CHEMICAL ABSTRACTS

Vol. 23.

JANUARY 10, 1929

No. 1

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Laboratory humidity cabinet. IRVING C. MATTHEWS AND ALOSCO M. BURGESS. Eastman Kodak Co., Rochester, N. Y. *Ind. Eng. Chem.* 20, 1239-40(1928).—A cabinet is built of alberene stone 1.5 in. thick, with all casings, ducts, etc., of Cu or brass, with a fresh air intake, water or steam spray nozzle, a series of eliminator plates of baffles, a blower to circulate air through the chamber, and thermostatically controlled steam coil as a heating unit, and with recording and automatic control instruments for both temp. and humidity. The cabinet can be used to simulate even tropical conditions, as it maintains temps. of 80-120° F. and any degree of humidity desired. It has proved satisfactory in making accelerated weathering tests on metals and other materials. It cost about \$1200, plus installation.

W. C. EBAUGH

Visible-action continuous-distillation apparatus for laboratory study of fractionation. RALPH H. ESPACH. Bur. Mines, *Repts. of Investigations* No. 2892(1928), 7 pp.—A detailed description of a tower which gives "very sharp and definite *seps.*" of petroleum products.

J. H. MOORE

Rapid filter for quantitative filtrations. NEO S. SERINIS. *Chemist-Analyst* 17, No. 4, 17(1928).—It is recommended to fill the pores of a Buchner funnel with asbestos, as in prepg. a Gooch crucible, and to place on top of the thin asbestos layer either a fluted or unfolded filter paper.

W. T. H.

Working with membrane filters. GUSTAV ECKERLIN. Staatl. Mainwasseruntersuchungsamt., Wiesbaden. *Kl. Mitt. Ver. Wasserversorg. Abwässerbeseitig.* 2, 119-23(1926); *Chem. Zentr.* 1927, II, 1743.—By careful operation and choice of the right kind of filter, just as accurate results can be obtained with membrane filters as with paper filters.

C. C. DAVIS

Electro-filters in the chemical industry. NACHTWEH. *Chem. Fabrik* 1928, 582, 593.—An elementary description of the Cottrell process, as practiced in Germany.

W. C. EBAUGH

Toy balloons and filtration. JOHN W. GARRETT AND C. D. HURD. Northwestern Univ., Evanston, Ill. *Ind. Eng. Chem.* 20, 1130(1928).—Instead of using rubber dams as aids in pressure filtration in the lab., as recommended by Gortner, *et al.*, ordinary toy balloons have been employed with success. Thus for the ordinary Buchner funnel a common toy balloon, when properly inflated, is of the proper size. Place it on top of the funnel after most of the solvent has been removed, but while the ppt. is still in a pasty condition.

W. C. EBAUGH

Suction as a filtering aid. GEORGE L. HOCKENYOS. Univ. Ill. *Chemist-Analyst* 17, No. 4, 18(1928).—To prevent using too much vacuum and possibly tearing the filter paper, it is recommended to use a water trap on the other side of the suction bottle. The trap consists of a stout test tube partly filled with water stoppered by a 2-holed rubber stopper carrying a tube that leads to the suction bottle and another tube that dips into the water and extends upward into the air. By varying the height of the water in the trap, the degree of suction can be regulated.

W. T. H.

Acid centrifugal pump. ALFRED KARSTEN-SALMONY. *Chem.-Ztg.* 52, 796(1928).—A new non-leaking pump of high-Si Fe, made by Wesseling Gusswerk Rheinguss, Wesseling.

J. H. MOORE

Centrifugal pumps with automatic equipment. N. C. BYR. *Iron Steel Eng.* 5, 332-3(1928).—A system of remote control of centrifugal pumps with automatic features is described. As the level in a water tower falls, a main pressure regulator starts a priming pump which exhausts the air from a main pump through a priming line and vacuum breaker. As the air is exhausted, the rising water fills the main pump casing up to the vacuum breaker. Here, the water raises a float closing the vacuum breaker switch starting the main pump motor and shutting down the priming pump motor. With increase in speed, the main pump motor develops enough pressure to shut off the

vacuum breaker, and at full speed, the pressure opens the main line check valve, and the water tower is filled, when the main pressure regulator opens and shuts the pump down. Simultaneously, the decrease in speed closes the main line check valve. Diagrams of (1) the general layout; (2) the automatic pumping system, (3) the vacuum breaker and (4) the elementary wiring system are given, together with an explanatory description.

S. L. B. ETHERTON

A new heating centrifugal. CARL HÜTTER. *Chem. Fabrik* 1928, 543-4(1928).—The app. is designed to sep. minerals by means of fused baths of salts of different sp. gravities. Small elec. fusion ovens are substituted for the baskets on the arms of the common type of lab. centrifugal. A motor in the base drives the app. at 2000 r. p. m. The powd. minerals and salts are fused in the ovens which may be heated to 600-900° and whirled for 3-5 mins., which is usually sufficient for a sharp sepn.

J. H. M.

Importance of standard thermometers in the testing of materials. W. H. FULWEILER. U. G. I. Co., Philadelphia. *Intern. Congress Testing Materials* 1927, II, 689-712.—When definite specifications are laid down for thermometers for various tests, the accuracy and reproducibility of the tests are increased. The cost of the thermometers is greatly reduced because "specially made types" are no longer necessary. Specifications are given for thermometers for the following A. S. T. M. tests: general purposes (3 ranges), distn. (high and low), Saybolt viscosity (3 ranges), softening or melting point (high and low), flash point in closed app. (high and low), flash point in open app., melting point of paraffin and petroleum, cloud and pure test (high and low), loss on heating, distn. of turpentine, heating test of tung oil (cf. *C. A.* 22, 2857). A tentative standard is proposed for the A. S. T. M. thermometer for Cleveland open cup.

G. CALINGAERT

Temperature control. ALVIN M. STOCK. *Ceramic Age* 12, 94-5(1928).—A brief description is given of the various types of pyrometers in common use.

W. H. R.

The development of automatic temperature control for industrial heating apparatus. A. N. OTIS. *Fuels and Furnaces* 6, 1387-94(1928).

E. H.

Pendulum viscosity tester. ALBRECHT AND WOLFF. *Petroleum Z.* 24, 551-5(1928).—The app. manufactured by Spindler and Hoyer, Göttingen, is described and calcn. methods are given.

M. B. HART

The Wolff lime tester for making a series of calcium carbonate determinations. A. HOCK. *Chem. Fabrik* 1928, 548.—Description of an app. for making several simultaneous volumetric CO₂ detns.

H. J. MOORE

A new condensation hygrometer. LEONARDO MARTINOZZI. *Nuovo Cimento* [N. S.] 5, No. 4, 137-42(1928); cf. *C. A.* 22, 3554.—M. describes a modification of the usual condensation type of hygrometer in which cooling is obtained by the evapn. of ether from the container holding the thermometer. It is provided with an indicator and direct reading scale. The instrument checked very well with an Assman psychrometer.

L. T. FAIRHALL

The pycnometer, its standardization and uses, with some notes on the accuracy of the instrument. WM. L. O. WHALEY AND ELLIS W. COATES. *Chemist-Analyst* 17, No. 4, 3-4(1928).—The difference between *sp. gr.* and *d.* is discussed and exptl. data are given showing the degree of accuracy that can reasonably be expected in work with the pycnometer of the type that is fitted with thermometer and capillary outlet tube.

W. T. H.

Practical study of the pyrometer. G. B. BROOK AND H. J. SIMCOX. *Heat Treating and Forging* 14, 1063-5(1928).—Means of preventing errors occurring in pyrometers are given. To insure against induction, the following arrangement is adopted. A Weston Elec. millivoltmeter (4" × 5") is placed in a Swedish Fe shell and so surrounded by another that between the 2 there is an air-gap. The instrument is read with a lens arrangement, the error never being greater than 0.5 m. v. or 8°. In order to eliminate errors due to the leads from the cold junction to the recorder controlling the reheating furnace, it has been found necessary to use Pb-covered paper-insulated cable laid in underground ducts. Cast Fe, protected with a coating of equal parts of French chalk and graphite in 10% Na₂SiO₃ applied daily 1/16" thick, is found to be the best material for sheathing couples used in Al-reheating furnaces. To protect the couple, in gas-fired furnaces, against SO₂ and other furnace gases the last 2-3 ft. of the sheathing is covered by a jacket contg. lime. A quick-reading couple, which eliminates the time lag introduced by a sheathed couple and is used for frequently detg. casting temps., is constructed according to Marsh (*Foundry* 55, 213(1927)). It is insulated by a silica tube wound with asbestos to within 1/2" of the end of the couple, the contacts being made by the molten metal. The ends are cut off when they become alloyed,

thus making the life of a thermocouple 2 months; if it is 36" long and 20 immersions are made in a day.

A simplified cataphorizer. W. D. HORNG., Hershey Corp., Hershey, Cuba. *Ind. Eng. Chem.* 20, 1147(1928).—A convenient cataphoresis app., with simplified connections, for use especially in sugar work, is described. Disadvantages of the ordinary type are eliminated by discarding the usual glass connections and passing over each stopper end a short piece of heavy rubber tubing, which holds snugly an ordinary cork through which pass a glass tube of 2 mm. internal diam. and a Pt wire about 0.5 mm. in diam.

W. C. EBAUGH

The vacuum tube voltmeter and its use for p_H determinations and in electrometric titration. HEINRICH THIELE. *Gas u. Wasserfach* 71, 854-6(1928).—The use of the vacuum tube voltmeter is discussed and diagrams are given for 2 set-ups. R. W. R.

A magnetic micro-balance. E. WOEKIND. *Z. angew. Chem.* 41, 771-4(1928).—A modification of the well-known Pascal set-up for measuring the properties of weakly diamagnetic or paramagnetic compds. The balance is replaced by a micro-balance and the magnet is improved. The principle of the Pascal method remains unchanged. The details and diagrams needed for practical use are given.

A. L. HENNE

Standardized stirring machinery in the chemical industry. HANS WOLLENBERG. *Chem.-Ztg.* 52, 815-6(1928).—Although chem. factories cannot be standardized like automobile works, parts of chem. app. can be so prepd. American practice in designing and building stirring app. is cited as an example, and the hope expressed that in Germany a similar method of operation may be developed.

W. C. EBAUGH

"Hydro" density recorder for liquids. ERIK K. H. BORCHERS. *Chem. Fabrik* 1928, 504-5.—A process and app. for the automatic recording of the sp. gr. of liquids are described. Two tubes are dipped into the liquid to different depths, and compressed air is forced through them in the form of bubbles. The difference in pressure of air in the 2 tubes is a measure of the density of the liquid itself, and this is then transferred to the recording instrument.

W. C. EBAUGH

A protected reservoir and buret. BARNETT COHEN. Hygienic Laboratory, U. S. Public Health Service, Washington, D. C. *Ind. Eng. Chem.* 20, 1238(1928).—A reservoir bulb has a 2-way stopcock above, one opening leading up to an inlet for inert gas and the other to a by-pass tube connected with a buret below the reservoir. At the lower end of the reservoir is also a 2-way stopcock; one opening leads to a tube through which liquid may be drawn into the reservoir, and the other to the buret below. By proper manipulation of these valves the app. can be flushed out with inert gas, filled with a liquid as desired, and everything protected from access to air.

W. C. E.

A wing-top oxygen-gas burner. G. ROSS ROBERTSON. Univ. of California at Los Angeles, Calif. *Ind. Eng. Chem.* 20, 1240-1(1928).—To give a wing-top burner suitable for working glass when natural gas is used as a fuel, the needle valve mechanism of 2 Tirrill burners had $\frac{3}{4}$ in. S. A. E. standard male threads cut in them, and were then fitted into a short length of 1-in. brass rod bored out and tapped with corresponding threads. A short section of the original tube from the burner is inserted into the top of the device, while below it a section of $\frac{1}{2}$ in. brass rod connects with a galvanized iron floor flange used as a base for the burner. A current of natural gas is first run through one side of the burner, and then O is admitted through the other side under pressure regulation so as to keep the flame barely non-luminous. The burner does not work with H alone nor with water gas, but will operate if even 15% natural gas be mixed with the above. Even 75% H and 25% natural gas worked well.

W. C. EBAUGH

The "Analytical Ultra Lamp" for fluorescent analytical investigations. FELIX MÜLLER. *Chem. Fabrik* 1928, 561-2(1928).—Description of a C filament lamp contg. Fe and W which gives a continuous ultra-violet spectrum and may be used in open day light for a large no. of investigations.

J. H. MOORE

New Orsat adsorption tube. A. H. MOODY AND G. E. STEVENS. *Chemist-Analyst* 17, No. 4, 15(1928).—A diagram is shown of an improved type of absorption tube for use in the standard Orsat app. for the measurement of CO_2 , O_2 and CO in flue gases. The absorption tube consists of 2 concentric glass cylinders sealed to each other at both ends. At the upper end connection is made to a short length of glass capillary tubing by means of which the gas to be analyzed is introduced. The outer glass cylinder carries at the top a goose-neck tube for venting the tube to the atm., to a rubber bag or to another tube used as a water seal. There is also at the top a $\frac{3}{8}$ in. opening carrying a short length of $\frac{1}{8}$ in. glass tubing for convenience in filling the absorption tube. The cylinders are sealed off square at the bottom to form a shoulder which acts as a support when the tube is placed in the Orsat cabinet. An opening with 0.5

in. glass is made at the bottom of the inner cylinder to facilitate the introduction or removal of glass tubes used to increase the absorbing surfaces. Entrance between the inner and outer cylinders at the bottom is made through $10 \frac{3}{16}$ in. holes placed 0.25 in. from the bottom of the inner cylinder. The filling openings at the top and bottom can be closed by rubber stoppers. W. T. H.

The efficiency and economy of so-called "colloid mills." FELIX HEBLER. *Chem. Fabrik* 1928, 581-2.—Although mills (e. g., Plafson's) designated as "colloid mills" can reduce a portion of their charge to colloidal dimensions and disperse these in a given medium, the quantity of material thus converted is so small compared to the total charge, and the time of grinding and input of power are so great, one cannot consider them as either efficient or economical. Expts. are reported to support this view. W. C. EBAUGH

Improved method for cleaning platinum ware. CARL GOODRICH. *Chemist-Analyst* 17, No. 4, 18(1928).—Instead of pouring out the $K_2S_2O_7$ fusion, continue heating the crucible over a Meker burner, while rotating the contents, until the material is spread out as a dry solid over the entire surface of the dish and there is no further evolution of vapors from the mass. Then rinse under the tap. W. T. H.

A method for the determination of carbon dioxide tension in small quantities (5 to 10 cc.) of fluid. A. BECK. *Chirurgische Universitätsklinik Kiel. Biochem. Z.* 199, 21-8(1928).—A description of app. S. MORGULIS

Some technical improvements in Czapek's apparatus for determining surface tension. V. I. KAMINSKII. *Kujalnitzki Liman, Odessa. Zhurnal expl. Biol. Med.* 10, 21-2(1928).—The app., as shown in the figure, is adapted to measure the surface tension of a soln. by detg. the water pressure in the left-hand branch of the U-tube necessary to force air through the capillary end of the bent right-hand branch which dips 1-1.5 mm. below the surface of the tested soln. The first appearance of an air bubble is the end point, and the amt. of H_2O added is measured from a buret. The greater the surface tension the more H_2O will be required. A stop cock is provided for draining and setting the initial level in the app. S. MORGULIS

Type of hydrogen electrode vessel useful for solutions of high resistance. R. J. BEST. Univ. of Adelaide. *Australian J. Expl. Biol. Med. Sci.* 5, [3], 233-6(1928).—The construction and operation of the app. are illustrated and described. The sensitiveness of the app. was such that the point of balance on the potentiometer could be ascertained to within a tenth of a millivolt when working with a soln. of as low a cond. as 10^{-8} mhos. L. W. RIGGS

Industrial furnace design. R. S. WILE. *Ceramic Age* 12, 58-9(1928).—Recuperators and tunnel kilns are recommended to effect economy. W. H. RISING

Recuperator unit for industrial furnaces burning oil. A. E. WALDEN. *Iron Steel Eng.* 5, 334-5(1928).—The unit was designed to be placed in the off gas flues but can be adapted for other places. The superheater section is a steel tube upon which are placed cast iron rings or fins. The tube is rolled into steel or cast iron flanges at one end and into a U tube at the other. Inside there may be a flat twisted strip to induce a rotation of the air, or a thin closed tube to increase the velocity of the air. Steam superheaters have a heat transfer of 6-13 B. t. u. per sq. ft., and air heaters from 2 to 6 B. t. u. The 2-in. recuperator unit has fins $3 \frac{1}{2}$ in. outside diam. and 2 sq. ft. of area per foot of length. The 4 in. unit has fins 6 in. outside diam. and 6 sq. ft. per foot run and 13 sections per foot. For such a metallic heater unit the limits of superheating should not exceed $1000-1200^\circ$ but it has been more. For the best results the air pressure should be at least 16 oz. and the air from the unit will run about $500-700^\circ F$. The unit saves upwards of 15% of the fuel cost on the forge furnace. S. L. B. ETHERTON

Air conditioning equipment. WALTER BURR. *Iron Steel Eng.* 5, 328-31(1928).—In the fabric filter the air is forced through a cloth screen, but the dirt restricts the openings and makes resistance excessive. In the air washer effective for soot, metallic and oily particles the dust particles impinge on wet eliminator plates. In the water spray filter, the metallic parts corrode in a very short time. Corrosion is avoided in the viscous filter. This unit is more effective for particles which have no affinity for water. The air is drawn through a series of metal deflecting surfaces coated with a viscous oil. Different forms of automatic self-cleaning viscous filters suited for

various purposes are described. The total cost of operation of air conditioning equipment on a 3750 h. p. motor is between \$215 and \$225 a year. The air velocity through the filter varies from 400 to 450 ft. per min. and the pressure drop from 0.25 to 0.4 lb. A useful discussion is given.

S. L. B. ETHERTON

The use of wrinkled pipe in the new steamer "Bremen." W. PAUL. *Apparatebau* 40, 242-3(1928).—The pipe is wrinkled, or creased, on the inner side of the bend. Cf. C. A. 22, 3320.

J. H. MOORE

Modern foam (fire-) extinguishing apparatus. J. HAUSEN. *Chem. App.* 15, 232-3(1928).—A detailed description of a large continuous foam generator in which the dry material is stored in the top and sifted down through a funnel into a chamber where it mixes with hydrant H₂O to produce foam. Also 2 types of small app. for using dry material are shown.

J. H. MOORE

Factors in modern methods of pulverizing (HARDINGE) 13. Apparatus for the estimation of electroendosmosis (SCHONFELDT) 4.

Toggle-jointed gripping device for holding hot beakers or other laboratory apparatus. RUDI STARK (to Central Scientific Co.). U. S. 1,688,404, Oct. 23.

Inverted-reading thermometer for low-temperature measurements. J. CASARELLI. *Brit.* 286,425, Feb. 2, 1927. Structural features.

Liquid-expansion thermometer. SOC. ANON. DES PISTONS IDEAL ET SEGMENTS ETANCHES. *Brit.* 285,882, Feb. 24, 1927. Structural features.

Colorimeter. R. A. LEGENDRE. *Brit.* 285,848, Feb. 23, 1927.

Filters. FILTRATION ENGINEERS, INC. Fr. 638,478, June 11, 1927. A reinforcing network or sep. elements such as endless flexible cords are provided for the filter cake to form on. The network may be removed and passed over drying cylinders.

Filtering apparatus. MARIUS GERRIT WAGENAAR HUMMELINCK. Fr. 636,437, June 22, 1927.

Flexible tube filter. MASCHINENFABRIK BETH AKTIENGESSELLSCHAFT. Fr. 636,274, June 20, 1927.

Filter for liquids, particularly wines and alcohols. LUCIEN BEURET. Fr. 32,558, Nov. 19, 1926. Addn. to 545,009.

Rotary vacuum filtration apparatus. WALTON C. GRAHAM. U. S. 1,687,863, Oct. 16.

Light filter. FRANZ ZERNIK. U. S. 1,688,259, Oct. 16. Hydroxyquinolinesulfonic acids in which the H of the OH group may be substituted by Me or other hydrocarbon radical are used in filters for ultra-violet rays.

Reticulated filter and cooperating scraper blades for cleaning the filter. CHARLES ST. C. BURNS (one-half to Foist Kay). U. S. 1,689,277, Oct. 30.

Bag filters for air or other gases. NEW HAVEN SAND-BLAST CO. *Brit.* 286,128, April 5, 1927.

Filter for air or other gases. ANTONIN BOULADE (to Soc. de Carburateur Zenith). U. S. 1,688,326, Oct. 23.

Device for purifying air. W. H. YARDLEY. *Brit.* 286,356, Dec. 1, 1926. A device is described which may be suspended in the atm. of a room and which circulates air over a purifying liquid placed in the device.

Device (with a funnel containing a sieve and jet pipe) for separating coarse particles and aggregates from finely divided pigments or other materials. GEORGE GALLIE and BENJAMIN D. PORRITT (to Research Association of British Rubber and Tyre Manufacturers). U. S. 1,688,307, Oct. 16.

Distillation apparatus. I. G. FARBERIND A.-G. Fr. 638,254, July 26, 1927. In an app. for distn., rectification or evapn., the vapor has its speed increased by passing through a narrowed portion of the neck of the container and then suddenly greatly reduced in a wide portion which is so shaped that vapor is caused to descend before again ascending, and at this point solid or liquid particles drop from the vapor and are led back to the distn. vessel.

Bubble plate column apparatus for fractional distillations. THEODORE BAKER and WILLIAM A. PETERS, JR. (to E. I. DuPont de Nemours & Co.). U. S. 1,688,515, Oct. 23. Various details of construction are specified.

Apparatus for separating the first and last runnings in the distillation of alcohol or other liquids. LOUIS EMILE RIVASSEAU DIT RIVASSEAU-CHOCARD and ALCIDE DAGAND. Fr. 636,429, June 22, 1927. A densimeter controls the flow of liquid towards one or another receiver.

Specific gravity registers for milk, gasoline or other liquids, flowing through dispensing apparatus, etc. WALTER J. ALBERSHEIM. U. S. 1,689,858-9, Oct. 30.

Liquid manometer and associated devices for metering the flow of gases. CLARENCE A. DAWLEY. U. S. 1,689,776, Oct. 30.

Cooling and straining device for separating oil or other vapors from gases. D. M. SHANNON. Brit. 285,928, Aug. 26, 1926.

Rotative apparatus for washing gas with automatic circulation of the washing liquid. FRITZ HAGER. Fr. 636,266, June 30, 1927.

Annular radiator for vacuum evaporating, particularly sugar solutions. AUGUST GRÄNTZDÖRFFER. Fr. 638,584, July 30, 1927. Constructional details.

Luminous neon tube. RAYMOND R. MACHLETT (to Rainbow Light, Inc.). U. S. 1,689,146, Oct. 23. Electrodes are used having an area less than 1 sq. dm. per amp. and the walls of the tube adjacent the cathode are provided with a mirror of electro-positive metal such as Cs. Cf. C. A. 22, 3556.

Vacuum tube for producing soft x-rays. KARL W. DAUMANN (to C. H. F. Müller Röntgenrohrenfabrik). U. S. 1,688,854, Oct. 23. Structural features.

Electric vacuum tubes. F. Y. ROBINSON AND METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Brit. 285,784, Nov. 9, 1926. Several filaments are connected in parallel and various structural details are described. After being mounted, the filaments may be coated as described in Brit. 285,538 (C. A. 22, 4279) with oxide or with a metal or compd. subsequently converted to oxide or may be otherwise treated to reduce the "work function," e. g., thoriated W filaments may be treated with a reducing agent such as C. Cf. C. A. 22, 2689.

Röntgen tube. SIEMENS-REINIGER-VEIFA GESELLSCHAFT FÜR MEDIZINISCHE TECHNIK M. B. H. Fr. 638,464, July 30, 1927. The electrodes of a soft-ray tube are carried by a single insulating base. The walls are of very thin glass or of metal with a window of Be.

Röntgen-ray tube construction. NAAMLÖÖZE VENNOOTSCHAP PHILIPS' GLOEI-LAMPENFABRIEKEN. Brit. 286,436, Feb. 14, 1927. The anticathode forms the armature or rotor of a motor and may comprise a Cu cylinder with an inner cylinder of Fe. Various structural features are described.

Röntgen-ray apparatus. K. MAYER. Brit. 286,283, March 3, 1927. Structural features.

Cathodes of electron emission tubes. LA RADIOTECHNIQUE. Fr. 637,962, Nov. 26, 1926. Cathodes which can be used directly in industrial currents have a core of refractory metal such as W, a covering sheath of insulating refractory material such as MgO and a layer of metal capable of emitting electrons.

Electron discharge device with a cathode of misch metal. JAMES E. HARRIS (to Western Electric Co.). U. S. 1,689,338, Oct. 30.

Electric discharge tubes. B. JAMES. Brit. 285,949, Nov. 16, 1926. Luminous elec. discharge tubes or lamps filled with Ne, He or other rarefied gas are provided with electrodes made of wire or metal strip and wound into a conical coil. The tubes around the electrodes may be protected, strengthened or cooled by coatings of materials treated with P₂O₅, "carbonic snow" suspended in acetone, Hg or CHCl₃ or by an evacuated shell or a shell contg. "liquids or chemicals." Various details are described.

Electric discharge devices. C. V. IREDELL (to Westinghouse Lamp Co.). Brit. 285,884, Feb. 24, 1927. Thermionic electrodes are formed of a refractory metal having incorporated with it a metal of good electron emissivity and a small proportion of a metal of the Ce group. Thoriated W is preferably used as the main body but Zr, U or V may be incorporated in Mo. The metal of the Ce group and the electron-emitting metal are present as oxides or reduced metal. Numerous details of prepg. the material are given. Cf. C. A. 22, 1501.

Infra-red-ray generator. HECTOR P. MACLAGAN (to McIntosh Electrical Corp.). U. S. 1,688,124, Oct. 16.

Acetylene generator. R. NIER, E. E. NIER, E. NIER and M. EHMER (trading as Nier & Ehmer). Brit. 285,898, Feb. 26, 1927.

Acetylene generator. JEAN PIERRE GOUJON. Fr. 637,983, Nov. 30, 1926. Constructional details.

Heat exchange system and apparatus for heating water, etc., by combustion gases. RAY C. NEWHOUSE. U. S. 1,689,927, Oct. 30.

Heat exchange apparatus suitable for use with petroleum oils, water, etc. ARTHUR P. BROCKLEBANK (to Foster Wheeler Corp.). U. S. 1,689,910, Oct. 30.

Glass-coated pipe coil suitable for heat exchange between foods, etc., and heating agents. EDWIN J. HANSON (to Glascote Co.). U. S. 1,689,435, Oct. 30.

Rotary heat exchange apparatus suitable for use with industrial wastes. FRANK S. BROADHURST. U. S. 1,689,189, Oct. 30.

Furnaces suitable for heating metal sheets or other articles in annealing boxes, etc. FORREST W. MANKER (to Surface Combustion Co.). U. S. 1,688,393-4, Oct. 23.

Furnaces. WM. STEFF. Fr. 636,195, May 18, 1927. Construction of mech. grate furnace in which the fuel is fed into the hottest part of the furnace.

Tilting furnace and charging apparatus construction. DEMAG A.-G. Brit. 286,224, Feb. 28, 1927.

Furnace for heating tubes, rods, etc. HIRSCH, KUPFER UND MESSINGWERKE A.-G. AND M. TAMA. Brit. 285,893, Feb. 26, 1927.

Furnace rabble arm construction. EDWARD J. FOWLER (to Nichols Copper Co.). U. S. 1,687,935, Oct. 10.

Apparatus for rocking the hearth of a furnace. WESTINGHOUSE ELECTRIC & MANUFACTURING CO., LTD. Fr. 636,457, June 22, 1927.

Apparatus for generating steam for power purposes utilizing caustic soda, etc. ERNST KOENEMANN. U. S. 1,687,941, Oct. 16.

Apparatus for pressure treatments. HIPPOLYTE MARCEL LAMY TORRILHON. Fr. 637,969, Nov. 27, 1926. To enable distn. and other app. in which increased or reduced pressure is employed to be made of Al or other weak material not attacked by the reagents used, the whole app. is enclosed in a strong metallic casing in which a pressure can be produced equal to that in the app.

Washing apparatus for coal, slimes, etc. OZÉE DELPLAN AND ALBERT QUAIRIAUX. Fr. 636,341, May 19, 1926.

Ozono-sterilizer of high frequency. MAURICE MORGENSTERN. Fr. 636,323, Apr. 16, 1927.

Revolving vacuum drying apparatus. AUGUSTINUS EDVARD JONSSON. Fr. 636,188, Oct. 14, 1926.

Vibrating apparatus for use in crystallizing or other operations. A. KUHN. Brit. 285,638, Feb. 2, 1927.

Apparatus for the continuous treatment of liquids. AKTIEBOLAGET SEPARATOR. Fr. 636,254, June 20, 1927. An app. is described for mixing a liquid with another liquid or solid and sepg. the two or their products of reaction, the sepg. means comprising fixed elements in a sepg. field of force which divide the mixt. into relatively thin layers having an angle with the direction of the lines of force considerably smaller than the angle of friction of all the matters present.

Apparatus for drying or cooling flour, starch or similar materials. ALEX G. HUHN (to A. Huhn Mfg. Co.). U. S. 1,690,013, Oct. 30.

Storage tank for gasoline or other volatile liquids. CLEON R. JOHNSON (to Standard Oil Development Co.). U. S. 1,690,072, Oct. 30. The tank roof is supported by a plurality of columns, a portion of which are encircled by an expansible chamber which is connected with a vent leading through the tank roof.

Apparatus for catalytic reactions. THE SILICA GEL CORP. Fr. 638,252, July 26, 1927. Improvements in catalytic app. are described, whereby the catalyst is brought in contact with a gas, the gas and catalyst are sepd. and the catalyst is treated to remove poisons and brought back into the operation. Non-treated gas is caused to pass transversely through the reaction zone. The catalyst may be a hard silica gel and may be introduced into and carried along by the gas current.

Annealing pot. JAMES H. TAYLOR. U. S. 1,688,999, Oct. 23. An upper enlarged portion of the pot is thickened by compression in the direction of the axis of the pot.

Thermionic valves. C. H. F. MÜLLER A.-G. Brit. 285,843, Feb. 22, 1927. Control electrodes (which may be wound to form a grid) comprise parallel or twisted wires insulated from each other.

Thermionic valve. C. B. UFF (to Westinghouse Elec. & Mfg. Co.). Brit. 285,810, Feb. 21, 1927. A thermionic cathode is used with at least one other metallic electrode such as an anode or control electrode the surface of which includes C to prevent emission of electrons, e. g., an electrode of Ni or W may be carbonized by heating in illuminating gas, or to a temp. of 800-1000° in C₂H₂ for 1-2 hrs. and then annealed during several hrs. while gradually reducing the temp. The cathode may comprise W or Ni coated with a mixt. of BaO and SrO.

Thermostat. EVERETT H. WARR. U. S. 1,689,542, Oct. 30.

Thermostat for controlling electric circuits. LAWIS J. GREENAWALT (to Westinghouse Elec. & Mfg. Co.). U. S. 1,687,664, Oct. 16.

Thermostatic devices. PORTER H. BRACE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,689,814, Oct. 30. An element formed of a Ni alloy having a relatively high temp. coeff. of expansion, such as "invar" or Monel metal, is used with another element formed of an alloy contg. Fe 1-3 and Ni 1 part and also contg. Co 1-20%. Cf. C. A. 22, 703, 1256.

Thermostatic electric switch. VICTOR G. VAUGHN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,689,809, Oct. 30.

Thermostatic electric switch. ROGER W. MCBRIEN. U. S. 1,689,210, Oct. 30.

Thermostatic electric switch. AUGUST J. MORTAU (to Westinghouse Elec. & Mfg. Co.). U. S. 1,689,795, Oct. 30.

Thermostatic electric switch plug. CHARLOTTE ARNESEN. U. S. 1,689,007, Oct. 23. Structural features.

Thermostatic valve construction. ENOCH THEANDER. U. S. 1,688,291, Oct. 16. A valve is specified which is suitable for controlling the flow of gas to burners of water heaters, etc.

2—GENERAL AND PHYSICAL CHEMISTRY

Criterion

RAOUL PICRET.

Arch. sci. phys. nat. [5], 8, 293-329 (1926).—

R. gives reasons for his belief that the ether possesses the attributes of mass, vol. and inertia, and hence fulfills the criteria of a reality which may be used in the equations of mechanics. The weight of a cu. km. of ether is calcd. to be 0.000,119,158 kg. The theory is advanced that each atom or mol. is inseparably surrounded by an envelope of ether. When spherical atoms or mols. approach in collision they can never actually touch each other, but the kinetic energy of their motion is transformed into the potential energy of deformation, which their ether envelopes undergo when they are in a position of close proximity. When the particles rebound the potential energy of their deformed ether envelopes reappears as kinetic energy. Heat, light and other types of radiation arise from the vibratory commotion of the ether envelopes which is supposed to result when impact occurs. With heat, the mean amplitude of such vibratory oscillations of masses of ether is the sole measure of temp. In reality, one can speak only of the temp. of a solid body whose center of gravity is immobile. The temp. of a gas is detd. practically by that of the solid walls which confine it. The work applied in compressing a gas is divided between increasing the potential energy of deformation of the ether envelopes and increasing the velocity of the mols. Only the work corresponding to the latter action contributes to the rise in temp. of the gas caused by compression. If 2 atoms which collide are cylindrical, it may be shown that they will reach a state of equil. in which their ether envelopes merge with one another, surrounding both atoms and forming a very difficultly separable system which is considered to represent a chem. mol.

R. H. LOMBARD

The evolution of the chemical elements. B. CABRERA. *Anales soc. españ. fis. quím.* 26, 186-205 (1928); cf. *C. A.* 22, 1271.—A review, with particular reference to the Aston curve.

The new singular elements—a plane and a solid angle in space. V. J. NIKOLAEV. *Ann. inst. anal. phys. chim.* (Leningrad) 3, 553-61 (1927); cf. *C. A.* 21, 3528 (1927).

G. B. KISTIAKOWSKY

The atoms per unit volume curve of the elements, a study of the specific weights of the elements in the liquid state. L. H. BORGSTRÖM. *Finska Kemistsamfundets Medd.* 36, 76-81 (1927).—The sp. grs. of the elements in the liquid and solid states are found to be nearly alike, which indicates that the at. radii must be nearly the same. The sp. gr. at the m. p. is also found in nearly all cases to be 10 to 20% greater at the f. p. than at the m. p. even though the temp. differences may vary from a few up to 1000°. The atoms per unit vol. curve is preferable to Meyer's at. vol. curve because equally large differences in d. have the same magnitude at high and low ds. The curve shows that 2 successive values tend to fall in the ratios of whole nos.; that in many cases the points fall on straight lines; that the slight bend in the at. vol. curve between Ti and Cu does not appear; and that the values tend to be multiples of the element at the nearest min. As regards polymerized elements it is pointed out that the atoms per unit vol. (at. wt./sp. gr.) in liquid O₂ and O are as 0.106 to 0.071, or as 2:3.

H. C. DUUS

X-rays do not always give the true lattice of crystals. CH. MAUGUIN. *Compt. rend.* 187, 303-4 (1928).—The remarks of Friedel (*C. A.* 22, 3074) that the true unit cell of a cryst. lattice is not always indicated by x-rays is substantiated by 2 types of minerals, i. e., by biotite (black mica) and by the chlorites. In both cases the unit cell is "3 times too small."

A. L. HENNE

X-ray examination of the anhydrous sodium sulfate-aluminum sulfate system. F. A. STIGGLE. Penn. State College. *Science* 68, 156-7 (1928).—Exptl. work was done to det. whether the anhyd. products obtained by the evapn. of aq. solns. contg. Na₂SO₄ and Al₂(SO₄)₃ are solid solns. or mech. mixts. or contain new chem. compds. Evapn. was carried out at the h. p. and the resulting solids were heated to 400°. The x-ray examn. was made with the powd. material, Mo K α radiation being used. This procedure was followed with a series of 10 samples, various proportions of the Na and Al salts being used. The equimol. mixt. showed no lines characteristic of either Na₂SO₄ or Al₂(SO₄)₃ but gave a characteristic diffraction pattern of its own, indicating a new individual. Samples richer in Al₂(SO₄)₃ showed lines of Al₂(SO₄)₃ superimposed on the pattern due to the new compd. which remained unchanged. Samples contg. an excess of Na₂SO₄ showed lines due to the new compd. with other lines not due to Na₂SO₄. These observations show that NaAl(SO₄)₂ is a definite compd. and not a mech. mixt. or a solid soln. There must also be another double sulfate contg. more Na₂SO₄ than NaAl(SO₄)₂. The complexity of the patterns indicates a low cryst. symmetry and no attempt at an analysis has been made.

A. W. KENNEY

The symmetry of the growth form of pentaerythritol. H. SEIFERT. *Z. anorg.*

allgem. Chem. 474, 318-20(1928).—A note on the work of Schleede and Hettich (*C. A.* 22, 4293). S. confirms symmetry class S_6 (cf. *C. A.* 22, 1711). S. shows that growth of pentaerythritol crystals results in twinning, not agreeing with Schleede's statement. He formulates the twinning as a mirror image symmetry in reference to the base (001). Single etch figures on the prism faces in classes C_6 and S_6 show simple asymmetry rather than "polar" or "unpolar" conditions as Schleede and Hettich give. Liebisch's "pyroelectric" effects (*Grundriss der physikalischen Kristallogr.* Leipzig 1896, p. 141) depend on subdivision, and are probably related to piezoelectricity. G. R. Y.

A new method for measuring deliquescent crystals. E. E. FLINT. *Trans. Inst. Econ. Mineral Met.* (Moscow) 1928, No. 34, 73-6.—F. describes new equipment for shielding deliquescent crystals on a goniometer. It consists of a spherical glass shield which fits a small glass salver in which the desiccating agent is placed. The crystal is supported upon a rod passing through the center of the salver.

R. L. HERSHEY

A study of crystal structure and its applications. Diffraction of light by crystals. W. P. DAVEY. *Gen. Elec. Rev.* 31, 496(1928).—A detailed review. C. G. F.

X-ray studies of the structure of salt adsorbed on cellulose. R. H. ABORN AND R. L. DAVIDSON. *Mass. Inst. Tech. Nature* 122, 440(1928).—Three possibilities are suggested for the adsorption of salts by cellulose: (1) a mech. holding in which both cellulose and the salt retain their original structure, (2) a reaction forming a new structural arrangement, and (3) a mol. or ionic dispersion of the salt throughout the cellulose units, the cellulose being structurally unchanged. X-ray investigations with cellulose and starch and with the salts NaCl and $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$ show that below a certain concn. the salt is molecularly or ionically dispersed (possibility 1) while above this concn. crystals of salt exist as such (possibility 3). This concn. is about 30 g. of tungstate to 100 g. of starch, and about 5 g. of NaCl to 100 g. of starch. Since these quantities of the salts are in proportion to their mol. wts., the phenomenon may be a mol. one.

JAMES M. BELL

The applicability of Fresnel's law in deducing evidence in favor of surface structure from surface reflectivity. S. S. BHATNAGAR, D. L. SHRIVASTAVA AND N. G. MITRA. *J. Indian Chem. Soc.* 5, 329-42(1928).—Light reflected from the surface of a liquid contg. polar groups such as OH, COOH, NH_2 , etc., should have a different intensity from that calcd. from Fresnel's law, provided the first reflection takes place from mols. in the surface layer. The app. used to measure the reflected light is sensitive between 70° and 30° reflection and is described at length. The ratio of the observed deflection of the liquid compared to H_2O at their resp. Brewsterian angles for the following liquids are: H_2O 1.000, EtOH 1.125, PrOH 1.245, iso-PrOH 1.200, BuOH 1.269, iso-BuOH 1.271, AmOH 1.269, Me_2EtCOH 1.259, AcOH 1.167, propionic acid 1.222, butyric acid 1.302, isobutyric acid 1.241, benzene 1.550, toluene 1.532, *m*-xylene 1.524, MeOAc 1.141, EtOAc 1.183, PrOAc 1.214, iso-BuOAc 1.213, $\text{C}_2\text{H}_4\text{Cl}_2$ 1.403, PhNH_2 1.750, PhNHFt 1.686, PhNMe_2 1.704, PhNEt_2 1.659, $\text{MeC}_6\text{H}_4\text{NH}_2$ 1.720, $\text{MeC}_6\text{H}_4\text{NMe}_2$ 1.637, $\text{Cu}_2\text{Fe}(\text{CN})_6$ soln. 1.000, gelatin soln. 1.000. Calcd. ratios of intensities at various angles of deflection are not equal to observed ratios of deflections in all cases, probably because of the wrong values of refractive indices for the effective wave lengths. Compds. having polar groups show observed values greater than those calcd., while the reverse holds for others. The differences are always greater for compds. contg. polar groups. For aromatic hydrocarbons and amines the observed values are less than those calcd. at high angles of incidence. The amines alone show greater values at small angles, probably because of at least 1 orienting radical. In the aliphatic compds., observed values are always greater than calcd. values. The mean deviations from calcd. values are greater for aromatic amines, presumably having mol. orientation, than for aromatic hydrocarbons. Study is being continued along similar lines as well as on colloidal solns. with monochromatic light from ultra-violet to infra-red regions.

RAYMOND H. LAMBERT

The "viscosity of structure" of some sols of polymerized carbohydrates. S. TSUDA. *Keijo Univ. Kolloid Z.* 45, 325-31(1928).—T. describes a viscometer with horizontal capillary for the study of the rate of flow of structurally viscous colloids. The viscosity of starch paste follows the law of Ostwald, and not that of Hagen-Poiseuille. The concn.-viscosity relationship for starch paste is approx. expressed by the formula of Arrhenius, in which the consts. are a function not only of the material but also of the dimensions of the viscometer and of the pressure. The viscosity of sols of agar follow the law of Hagen-Poiseuille at 50° and of de Waele-Ostwald at 80° . Reheated to 50° , it follows the latter at first, and returns to its original state only after a long time.

G. CALINOARET

The structure of matter. 1. The periodic classification of the elements. OTTO RAINMUTH. *J. Chem. Education* 1312-20(1928); cf. *C. A.* 22, 4049. E. H.

Reactions in the solid state. E. KORDS. *Glastech. Ber.* 6, 44-50(1928).—A summary of the work of G. Tammann and others on the interaction of crystals, relation of the crit. temp. to the m.p.s. of the substances and the amplitude of the vibrations of the atoms in the crystal lattice. The effect of a change in the crystal structure of one of the components is discussed and applied to the reactions between quartz and CaCO_3 , Na_2CO_3 , and K_2CO_3 . E. VALDEN

Gases with molecular attraction. KAMEKICHI SHIBA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 740-7, English Ed. 1, 65-6(1928).—Continuation of S.'s previous papers (*C. A.* 22, 3326). S. discusses the fundamental assumptions of the classical kinetic theory of gases and proposes a simple correction. The discussion is made mainly on the method of statistical mechanics, and the result is that the so-called ergodic hypothesis (quasi-ergodic) may not be used with 2 or more systems in thermal equil. The following expression is proposed as a correction of Maxwell's law of distribution of mol. velocities: $e^{-\frac{3m}{2\epsilon} (u^2 + v^2 + w^2)}$, where ϵ is the mean kinetic energy depending on the sp. vol.; this holds probably true, at least in sufficiently rarefied gases at sufficiently high temps. Some qual. results of the above corrections are pointed out. Remarks are made on the new statistics of ideal gases. A. L. HENNE

The behavior of gases in thin foams. ERNST BIESALKI. *Tech. Hochschule, Berlin. Z. angew. Chem.* 41, 853-6(1928).—It is well known that when the gas contained in the bubbles of a foam is a mixt. of O and H, it will not react on contact with a flame or a red-hot metal. But if colloidal Pd is present in the foam, reactions will be favored. H and O, C_2H_4 and H, C_2H_2 and H will react very smoothly. Salicylic acid and oleic acid have been hydrogenated by this method with much more ease than by the customary Paal method. A. L. HENNE

Homopolar union in excited hydrogen molecules. EGIL A. HYLLERAAS. *Z. Physik* 51, 150-8(1928).—A mathematical treatment of the case of action between 2 H atoms, one ordinary and one excited, leads to 4 solns., 2 leading to elastic collision and 2 to mol. formation. Both of the latter have symmetrical kernels, one with asymmetric and the other with symmetrical electron, corresponding to para term and an ortho term of the H mol. The curve shows a reduction of dissocn. work and an increase of moment of inertia against the ordinary state. G. B. TAYLOR

The rate of evaporation of molten cadmium in a high vacuum. ARTHUR A. SUNIER. *Univ. of Rochester. J. Phys. Chem.* 32, 1516-21(1928).—Sixty evapns. of Cd were carried out in Pyrex equipment at temps. from 335° to 425° at a pressure usually reaching 2×10^{-4} mm. by the end of the evapn. The av. rate of evapn. in g. per sq. cm. of surface per hr. ranged from 2.0 g. to 12.6 g. The widest variation at a given temp. (352°) was from 2.1 g. to 10.0 g. The theoretical rate of evapn. is calcd. from Herz equation $m = p\sqrt{M/2\pi RT}$, where m = g. evapd. from 1 sq. cm. in 1 sec., p = vapor pressure in bars, and M = mol. wt. The actual rate of evapn. varied from 4.2% to 40% of the theoretical rate. It seems probable that the low rates of evapn. were due to the fact that the surface of the Cd was dirty on account of the presence of CdO. D. H. P.

The absolute velocity of water molecules which are emitted from crystal hydrates upon dehydration. A. PREVDITSEV. *Inst. Physics and Biophysics, Moscow. Z. Physik* 51, 126-49(1928).—By means of a torsion and a micro-balance the dehydration velocities of $\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$, $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ and $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$ were measured. The abs. velocities of the H_2O mols., leaving the hydrates were calcd. and from these the heats of hydration. The heats agreed with values in the literature. G. B. TAYLOR

The volume isobars of water up to the melting-point curve. G. TAMMANN AND W. JELLINGHAUS. *Z. anorg. allgem. Chem.* 174, 225-30(1928).—The results obtained by Bridgman and Amagat are discussed critically. Tables and curves are given to substantiate the discussion. T. and J. repeated the measurements of the vol. pressure relationships up to 1500 kg./sq. cm. Their results show that Bridgman's values for 1000 and 1600 kg./sq. cm. are decidedly too great. The expl. method is briefly described, with references to a more detailed description. L. L. Q.

Properties of aqueous solutions, especially of sodium chloride solutions. A. A. LÄRRNER. *Tech. Hochschule, Dresden. Arch. Wärmewirt.* 9, 233-42(1928).—The sp. heat of NaCl solns. was studied between 20 and 100° in an adiabatic calorimeter with elec. heating. In a 3% soln. the sp. heat rises from 0.98 to 0.99 in this range; in a 26% soln. the sp. heat is about 0.75 at 25°, falls linearly to 0.69 at 75°, and then curves off to 0.51 at 100°. Values for intermediate comps. fall between these, but no

numerical data are given. L. then illustrates the formation of total heat curves, and their use for calcg. heats of diln. JAMES W. THIELE

An accurate method for observing the meniscus of liquids confined in small tubes. J. T. LLOYD. *Am. J. Pharm.* 100, 601(1928).—To overcome the refractive power of test tubes and make clear observation of their contents possible, the tube is submerged in a sq., wide-mouthed bottle of cedarwood oil of the same n as the glass of the tube. Naturally a bottle with plain sides must be selected. By this method the sides of the tube are apparently practically obliterated and clear observation of the films is made possible. W. O. GAESSLER

Can atmospheric oxygen be kept out by means of superimposed layers of different fluid substances? HANS SCHMALFUSS AND WILHELM PESCHKE. *Chem. Staatsinstitut, Univ. Hamburg. Biochem. Z.* 198, 487-93(1928).—Of the 13 fluid substances tested amyl alc. was most effective, anisole least effective in keeping out atm. O_2 . One or another fluid was found preferable, depending on whether it is intended for a long or brief period. The depth of the superimposed layer is of little significance. The O_2 enters the soln. not through the upper layer of protecting fluid but through the space between the container and the substance; this can be demonstrated with the aid of indicators (alk. pyrogallol). The O_2 can be kept out for long periods either by covering the soln. with melted paraffin which cools and solidifies very quickly, or in case the soln. has too high a temp., by covering it with a layer of a substance boiling at that temp., such as ether, and with the aid of a reflux condenser keeping this from evap. A 2-mm. layer is sufficient. S. MORGULIS

The electrolytic coagulation of colloids. V. Pure silicic acid sols. E. LASKIN. *Kolloid-Z.* 45, 129-36(1928).—The p_H of SiO_2 sols was detd. by the H electrode, by the quinhydrone electrode and by cond. measurements. Results are in fair agreement. Various sols were prepd. and the coagulating actions of such materials as $CaCl_2$, $BaCl_2$, $LiCl$, $AlCl_3$, $La(NO_3)_3$, $Th(NO_3)_4$ and $FeCl_3$ were studied. Dyes such as night blue, neutral red, rhodamine 6 G and methylene blue also have a coagulating action but SiO_2 is pptd. as fine flocs or as a powder and the material is deeply dyed. The principal factor in coagulation with electrolytes appears to be the dehydrating action on the colloid particle by ions which are strongly hydrated. Acid dyes produce no coagulation. These sols closely resemble mastic sols but are sharply distinguished from sols like As_2S_3 or WO_3 in which the existing H ion is neutralized by other cations. R. H. L.

Adsorption phenomena in solutions. XIV. Studies of the adsorption of homologous monobasic acids. BORIS NEKRASOV. *Z. physik. Chem.* 136, 18-33(1928).—The influence of the solvent on adsorption is not yet clear. Five charcoals were prepd. in these expts.: (1) blood charcoal known as "Carbo medicinalis Merck"; (2) no. 1 purified by the method of M. Dubinin (cf. *C. A.* 22, 3329), (3) wood charcoal for gas masks; (4) no. 3 purified as in (2); (5) sugar charcoal. The purification yields charcoals which adsorb the ions of HCl equally. The best adsorbent for I from $KI-H_2O$ solns. was purified blood charcoal; the poorest adsorbent was sugar charcoal. Adsorption of 0.01 M formic, acetic, propionic, butyric, valeric, caproic, and heptylic acids from water solns. on the 5 charcoals and stearic acid showed that the purification increased the activity of the blood charcoal, decreased the activity of the wood charcoal, and that the results for sugar charcoal contradict Traube's rule. Stearic acid showed no adsorption for the first 4 acids. In Et_2O and $EtOH$ solns., by using the 5 charcoals and adding caprylic, pelargonic, lauric, myristic, palmitic and stearic acids to the above list the purification of the charcoals showed the same results as those for water solns. Traube's rule holds for part of the series only, a min. occurring at 7-12 C atoms. Sugar charcoal adsorbs only the lower members of the series. 0.01 M solns. of the fatty acids in water, $MeOH$, $EtOH$, $MeCOMe$, $EtOEt$, petroleum ether, benzene, toluene, $CHCl_3$, CCl_4 , CS_2 on the unpurified charcoal showed that the results could be divided according to solvents into 2 groups, O-contg. and non-O-contg. solvents. Those in the former show sharp minima in the adsorption curve with the exception of water, and for all of them Traube's rule holds from about butyric acid up the series. For the second group the min. adsorption is very weak or absent, and a weak or no tendency to obey Traube's rule. Petroleum ether falls between the 2 groups, undoubtedly because it is a mixed solvent, in which minima are often observed. There is no parallelism between surface tension of the solvent and adsorption. Dielec. strength gives a qual. regularity for the first group but none for the second. Charcoals are composed of 3 constituents: (A) pure C, (B) hydrocarbons of high mol. wt. and (C) chem. active and inactive (SiO_2) ash. Blood and wood charcoal have different proportions of A and B, while sugar charcoal is practically pure A. This classification brings the results in agreement with Rehbinder's "displacement" rule. XV. Hydrolytic and molecular adsorption of alkaline earth

halides on charcoal. MARK CHEPELEVSKII. Inst. Political Economy, Moscow. *Ibid* 34-44.—Systematic investigation of adsorption of alk. halides on active charcoals measured at the same initial concn. showed that adsorbability depends on the cation. The series for cations is: $\text{Li} > \text{Na} < \text{K} < \text{Rb} < \text{Cs}$; for anions: $\text{I} > \text{Br} > \text{Cl}$. The halides of Be, Mg, Ca, Sr, and Ba were studied in 1/60 *N* solns. on Merck's blood charcoal and on sugar charcoal. The adsorption of the anions of Merck's charcoal was of the same order; Be. showed a very high adsorbability, the remaining cations about the same lower order. Sugar charcoal gives about the same results with the exception of Ba, which shows a high adsorption, due undoubtedly to adsorbed CO_2 from the activating process. The bicarbonate formed by the CO_2 reacts with the adsorbed cation, pptg. BaCO_3 in the pores. Proof of this is shown by the parallelism of carbonate soly. with the cation adsorption and non-dependence on anion. Mol. adsorption is a complicated process and may be due to secondary reactions as shown above.

ARTHUR FLEISCHER

Adsorption from concentrated solutions and the adsorption of liquids. R. DEFAY. *Bull. soc. chim. Belg.* 37, 63-87(1928).—The Ostwald theories have been tested experimentally; they are correct with charcoal and aq. solns. of AcOH . D. criticizes the assumption that the solute and the solvent are adsorbed independently of each other. The results are equally well explained without this assumption; he uses Schmidt's idea of the adsorption max. A method has been devised for measuring the adsorption of a liquid on a solid and has been applied to the measurement of the adsorption of water by kieselguhr.

A. L. HENNE

The adsorption of vapors. ARTHUR FLEISCHER. *Yale Univ. Am. J. Sci.* [5], 16, 247-58(1928).—The Zsigmondy view of adsorption as a combination of surface adsorption and capillary condensation as the explanation of vapor adsorption is held as leading to the type of curve often obtained with vapor systems. Langmuir's views are adopted for the surface adsorption and Anderson's equation is applied for capillary condensation. It is shown that Coolidge's hypothesis of the particular form of curve applicable to polar liquids is inadequate and that Patrick's interpretation must be modified. A. F.

Studies on the physical chemistry of resorption. I. P. I. JURŠIĆ. *Pathol. Inst. Charité, Univ. Berlin. Biochem. Z.* 196, 223-45(1928).—The diminution in attraction or repulsion effect of ions on the electrically charged water column in the pores of a charged membrane is not in agreement with the results obtained in model expts. If NaCl is present on one side of a membrane and a salt of a multivalent ion on the opposite side, the flow of water is in the direction from the first to the latter, the velocity of the transport being directly proportional to the concn. of both isotonic solns. If on one side of the membrane there is a univalent cation and on the other a multivalent ion, the water flows in the direction cation \rightarrow anion, the velocity again being proportional to the concn. of the 2 isotonic solns. Theoretical discussion of the significance of these exptl. observations should be consulted.

S. MORGULIS

Coagulation studies on quartz suspensions. J. A. HANLEY. *Kolloidchem. Beihefte* 25, 281-99(1927).—Quartz powder was sepd. into fractions contg. particles approx. the same size by a sedimentation process. Suspensions of 4 such fractions were prepd. and observations were made of the process of coagulation on the addn. of gradually increasing amts. of lime water to the several fractions separately and to certain mixts. The flocculation of single fractions takes place in 5 steps. (1) The particles tend to stick together. This tendency increases with size of particles and with the addn. of electrolyte. (2) Permanent clusters and flocks are formed which are not very dense. (3) Dense clusters appear which behave like individual particles of larger size. (4) The small clusters coalesce into larger flocks, which settle out quickly. The supernatant liquid may remain cloudy for a long time. (5) Chain-like aggregates are formed by the coalescence of small groups. Beyond this, further addn. of electrolyte has no effect. With mixts. of fractions the larger particles attract the smaller ones, the latter concg. on the larger particles in a given clump. The addn. of electrolytes does not result in fractionation according to particle size. The phenomena are illustrated by photomicrographs.

HARRY B. WEISER

Preparation of a chemically indifferent quartz material of well-defined size of grain and character of surface. G. KRAUSS. *Kolloidchem. Beihefte* 25, 299-314(1927).—By a sedimentation process a suspension of quartz powder was made contg. particles less than 0.02 mm. in diam. This was treated with concd. HCl and the ppt. obtained was extd. repeatedly with HCl during 3 or 4 days and finally with distd. H_2O to the pptn. concn. of the acid. The last trace of acid was removed by heating in a Pt dish. The powder was again suspended in water and the suspension boiled from 1/2 to 1 hr. in a thin-walled flask over a free flame. This operation served to sterilize the particles

and thus to prevent the growth of a micro-vegetation which covers the particles with a slimy film. Finally the purified particles are sepd. into fractions as uniform as possible by a process of elutriation, which is described in detail. Photomicrographs are given which show the uniformity of several fractions.

HARRY B. WEISER

Slipping phenomena in the sedimentation on an inclined surface. G. KRAUSS AND R. RÜGER. *Kolloidchem. Beihefte* 25, 314-8(1927).—Detns. were made of the angle of slipping of quartz particles in very dil. solns. of HCl, KCl, CaCl_2 , $\text{Ca}(\text{HCO}_3)_2$, AlCl_3 , $\text{Ca}(\text{OH})_2$, KOH, and NH_4OH . The app. consisted essentially of a rectangular glass vessel in the bottom of which were placed wedges made of black glass. The method was as follows: 0.27 g. of quartz, diam. of grains 0.01-0.02 mm., was suspended in 200 cc. of electrolyte and allowed to settle on a glass wedge. With 0.002 N CaCl_2 the surface of the wedge was uniformly covered with quartz when the angle was between 1.5° and 28° . With larger angles the particles showed a tendency to slip and at 47° the slipping was sufficiently great in 5 min. to give a white streak at the base of the black wedge. This was taken as the end point. The angle of slipping is altered by changing the elec. repulsion between the quartz granules and the glass surface. In accord with Schulze's law the discharging action of the 3 ions Al^{+++} , Ca^{++} , and K^+ was found to be in the ratio 1000:10:1. On the other hand, the discharging action of univalent H^+ was greater than that of bivalent Ca^{++} .

HARRY B. WEISER

The influence of dilute solutions of electrolytes on the mobility of suspended quartz-sand filter. M. STORZ. *Kolloidchem. Beihefte* 25, 319-53(1927).—The amt. of suspended quartz retained by a sand filter depends on the amt. of suspension flowing through and the electrolyte content of the suspension and of the wash water. In a sp. case 53.3% of fine quartz was washed out with a given amt. of H_2O contg. no HCl, 29.5% with 0.0001 N HCl, 6.2% with 0.00025 N HCl, and 2.8% with 0.005 N HCl. A small quantity of electrolyte below the pptn. value greatly decreases the amt. of fine quartz washed out from a sand filter and tends to prevent rearrangement of particles in the filter. This is of great importance in practice. The electrolyte content which detts. the retention and proper distribution of particles capable of moving also detts. the permeability of the filter to water.

HARRY B. WEISER

The influence of small concentrations of electrolytes on the sedimentation of quartz suspensions. H. SALLINGER. *Kolloidchem. Beihefte* 25, 353-60(1927).—Fifty cc. of CO_2 -free suspension contg. 2 to 6 g. of quartz was pipetted into a glass cylinder of 4 cm. internal diam., dild. with 50 cc. of H_2O and finally mixed with 50 cc. of electrolyte. This was allowed to stand 5 hrs., and a 5-cc. sample was withdrawn 6 cm. from the top and the quartz content detd. The following conclusions are reached. Curves showing the effect of increasing concn. of electrolyte on the degree of sedimentation are similar in form. There is an initial region in which the effect is slight, followed in turn by regions in which the sedimentation is (a) greatly increased and (b) not greatly changed. With the strongly adsorbed electrolytes such as AlCl_3 and $\text{Ca}(\text{OH})_2$, it is necessary to start with higher initial electrolyte concns. for coned. suspension than for dil. if comparable results are to be obtained. Observations with the strongly adsorbed AlCl_3 and $\text{Ca}(\text{OH})_2$, on the one hand and the weakly adsorbed KCl on the other show that the pptn. value for strongly adsorbed electrolytes increases with increasing suspension concn. and for weakly adsorbed electrolytes, decreases with increasing suspension concn. The curves for KCl, NaCl, and Na_2CO_3 are very similar. The weak action of Na ions as compared with K ions is shown at all chloride concns. Na_2CO_3 acts less strongly than NaCl because of the peptizing action of OH ion formed by hydrolysis.

HARRY B. WEISER

Adsorption measurements on quartz. H. SALLINGER. *Kolloidchem. Beihefte* 25, 360-78(1927).—Adsorption measurements on quartz were made with varying concns. of the following electrolytes $\text{Ca}(\text{OH})_2$, $\text{Sr}(\text{OH})_2$, $\text{Ba}(\text{OH})_2$, LiOH, NaOH, KOH, NH_4OH , Li_2CO_3 , Na_2CO_3 , K_2CO_3 . The adsorption values with hydroxides were made within an hr., since the quartz is attacked by prolonged action of the bases. The exponent n of the adsorption isotherm increases with the amt. of quartz. The n value decreases in the series Ca, Sr, Ba, and in the series Li, Na, K. This order is the reverse of the order of radius of the unhydrated ions. With $\text{Ca}(\text{OH})_2$, $\text{Sr}(\text{OH})_2$, and $\text{Ba}(\text{OH})_2$ the n values are proportional to the reciprocal of the square of the cation radius. The theoretical significance of this is not known.

HARRY B. WEISER

Theoretical deductions from the measurement of the angle of slipping. H. SALLINGER. *Kolloidchem. Beihefte* 25, 384-401(1927).—Equations are deduced for calcg. (a) the charge on quartz particles from the angle of slipping, (b) the abs. value of the quartz water potential, (c) the thickness of the elec. double layer from the observations on slipping and the adsorption measurements with quartz, and (d) the dependence of the

elec. charge of the quartz particles on the valence and concn. of ions from the slipping observations. The data of Krauss and Rüger on slipping of quartz particles and the adsorption measurements of Sallinger (see preceding abstracts) were used to test the validity of the equations.

HARRY B. WEISER

Model of the Pickering emulsion. R. E. LIESEGANG. Inst. physik. Grundlagen Med., Frankfurt a. M. *Kolloid. Z.* 45, 370-1 (1928).—CHCl₃ and powd. NaCl are shaken with a dil. soln. of Löffler's methylene blue. The drops of CHCl₃ are prevented from running together by the undissolved NaCl. The preps. keep very well, especially if the H₂O phase is satd. with NaCl.

G. CALINGAERT

New Hypotheses as to the cause of the formation of layers in suspensions. G. KRAUSS. *Kolloidchem. Beihefte* 25, 378-84 (1927).—Investigations of Ehrenburg and Ungerer (C. A. 16, 1169) led them to conclude that layer formation was due to variations of any kind which sep. the particles into well-defined groups. The setting of the particles into layers follows Stokes' law. Every layer corresponds to a definite grain size and the individual layers show distinct differences in weight and size of particles. K. favors the hypothesis that layer formation is due to discontinuity in the rate of fall of particles. Sharp differences in particle size in natural soil, regular d. differences and complicated explanations of the stepwise velocity of fall appear less probable than the explanation advanced by Ehrenburg and Ungerer.

H. B. W.

Contribution to the theory of adsorption from dilute solutions. H. SALLINGER. *Kolloidchem. Beihefte* 25, 401-12 (1927).—Adsorption measurements on quartz were made with the hydroxides of Ca, Sr, Ba, Li, Na, and K. The detd. adsorption values are in good agreement with the values calcd. by means of the equation $\ln \frac{S}{S-x} \cdot \frac{c}{S} = K_s$,

where x is the adsorption value, S is the satn. value of the adsorption, c the concn. and K_s a const. For the bivalent hydroxides the K_s values are practically the same (0.49), while for univalent hydroxides, the values are quite different (0.16 for LiOH, 0.32 for NaOH, and 0.93 for KOH). This is accounted for by assuming the const. K_s to be the quotient of 2 opposing forces: the quartz action which tends to hold the cations on the surface of the quartz and the H₂O action which tends to hold the ions in soln. If the quartz action is assumed to be approx. const. the reciprocal of the K_s values in a group of like-valent ions will give a relative measure of the H₂O action. Taking the degree of hydration as a measure of the H₂O action $K_s = f(r_h^3 - r_u^3)$, where r_h and r_u represent the radius, resp., of the hydrated and unhydrated ion and f is a const. for like-valent ions. The degree of hydration of bivalent ions differs much less than of the univalent ions; hence the K_s values for the hydroxides of Ca, Sr, and Ba are nearly the same, while for the hydroxides of Li, Na, and K, the K_s values vary appreciably. The relative K_s values for Ca, Sr, and Ba are shown to be in the ratio 1:1:1 and for Li, Na, and K the ratio is 1:2:5.8. Conclusion: the K_s values within a group of like-valent cations are approx. inversely proportional to the degree of hydration of the ion.

HARRY B. WEISER

Dependence of the mass (x) of an adsorbed material on the mass (m) of the adsorbent. H. SALLINGER. *Kolloidchem. Beihefte* 25, 412-22 (1927).—An attempt was made to show the dependence of the amt. adsorbed (x) on the amt. of adsorbent (m) by means of the equation $x = K \cdot m \cdot \log d/d_0$, in which $d = v/O = v/mO_1$ and d_0 is the thickness of the adsorption layer which for a const. y/v is taken as const. K is a const. and O_1 is the surface of 1 g. of adsorbent. This equation relating the 2 values held for observations of Schmidt (C. A., 5, 416) on the adsorption of I₂ from Cl₄ by sugar charcoal, Freundlich's data (*Kapillarchemie* (1922) 237; cf. C. A. 16, 1803) on the adsorption of AcOH from soln. by blood charcoal, and the adsorption of Ba(OH)₂ from aq. soln. by quartz. If d_0 is known, it is possible to calc. the sp. surface O_1 of the adsorbent from absorption data with variable (m) and const. (y/v) by means of the equation $O_1 = v/m \cdot d_0 \cdot 10^3 / K \cdot m$.

HARRY B. WEISER

Calculation of the hydrolysis constant of dissolved sodium carbonate by means of adsorption measurements on quartz-sodium carbonate and quartz-sodium hydroxide. H. SALLINGER. *Kolloidchem. Beihefte* 25, 423-4 (1927).—The hydrolysis const. of Na₂CO₃, K_h , was calcd. from the adsorption data by means of the expression $K_h = [2c' \cdot (c' + x) / (c - [x - 2c'])] \cdot 10^{-4}$, in which c is the amt. of dissolved hydroxide, c' the entire alkali titer of the soln. after adsorption and x the amt. of adsorbed hydroxide. c and x are obtained from adsorption measurements on quartz-Na₂CO₃ and c' can be calcd. by means of x from the adsorption isotherm for quartz-NaOH. In a sp. case a value of $K_h = 3.4 \times 10^{-4}$ was obtained as compared to Auerbach and Pick's (C. A. 6, 10) value 1.9×10^{-4} at 25°.

HARRY B. WEISER

Calculation of the electrolytic dissociation constant of ammonia from adsorption

data on quartz-ammonia and quartz-potassium hydroxide. H. SALLINGER. *Kolloid-chem. Beihefte* 25, 424-7(1927).—The dissozn. const. k of NH_4OH was calcd. from the adsorption data by means of the equation $k = (c')^2/V(t + c')$, in which V is the volume of the soln. in cc. and c the total amt. NH_3 and c' the active mass of NH_4OH in millimoles in V cc. after adsorption. c is detd. directly and c' is calcd. by means of x from the adsorption isotherm of quartz-KOH. In a sp. case the value of K by the method was found to be 2.5×10^{-5} .

HARRY B. WEISER

Orange-colored and orange-red colloidal gold solutions. P. P. VON VEIMARN. *Kolloid Z.* 45, 366-70(1928).—True orange-colored Au sols leave a clear colorless dispersoid after the Au has been dissolved by KCN. W. prepares them by reducing $\text{AuCl}_3 \cdot \text{HCl}$ with Na citrate. Upon addn. of KCN the orange-red sols turn orange, showing that the red particles are dissolved first. The orange Au sols prepd. by the reduction with tannin owe their color to the yellow dispersoid after the tannin has been oxidized by the Au salt.

G. CALINGAERT

The identification of unreduced gold compound in red gold sols by the ammonia test. P. P. VON VEIMARN. *Kolloid-Z.* 45, 203-7(1928).—A study has been made of the ring formed when NH_3 is added to a test tube contg. Au sol and known to contain some Au compd. Na citrate causes the colloid Au to become highly dispersed. The ring need not be formed quickly nor need it assume a blue color. Three groups of Au compds. may be obtained by the NH_3 test, i. e., those forming a blue ring quickly, those showing practically no ring and those showing a ring from purple-red to blue after a long time. Au is a very difficult material to use for dispersoidal studies since it is a multivalent element forming complex compds. V. expects to prep. a sample of disperse Au which will be contradictory to the view now held by many as to this process.

R. H. L.

Unprotected homogeneous silver hydrosols. III. J. VOIGT AND J. HEUMANN. *Z. anorg. allgem. Chem.* 173, 27-44(1928); cf. *C. A.* 22, 2502.—Ag hydrosols were prepd. by reduction of Ag_2O solns. by hydrazine sulfate, hydrazine hydrate and formol. The presence of alkali greatly influences the sols obtained. No treatment with Au or Ag nuclei was given. Hydrazine sulfate produces the finest sol and formol the poorest. On concg. from 0.001 to 0.005% Ag the sol became relatively unstable although a no. of particles did not appear to change. Coagulation was studied by observation of color change. The method of prepn. affects the first stage of coagulation while in later stages the properties of the medium are of most importance.

R. H. LAMBERT

The "solution" of colloidal silver in hydrogen peroxide. H. KOLLER-AEBY. *Kolloid-Z.* 45, 371-4(1928).—K. repeats the expt. under various conditions, and describes an intermediate stage in which the $\text{Ag}-\text{H}_2\text{O}_2$ system is colored a beautiful steel blue.

G. CALINGAERT

The solution of a metal in a melted salt. WILHELM EITEL AND BRUNO LANGE. *Z. anorg. allgem. Chem.* 171, 168-80(1928).—A study has been carried out with "pyrosols" by means of a specially heated ultramicroscope, which is described. Photographs aid in giving a clear picture of the app. Pb in PbCl_2 was first studied and no colloidal particles could be detected. The same results were found with Cd in CdCl_2 . By calcn. from Stoke's law, particles 35.5μ in diam. should be present if colloidal. A study of pyrosol with a Tyndall beam shows that no change in polarization occurs on adding Pb to melted PbCl_2 , giving evidence of compd. formation. Thermodynamic considerations favor mol. dimensions of particles. There is strong evidence that subhalides may exist which may dissociate with heating; the free metal formed causing color in the melt. On solidification, ultramicroscopic particles are observed.

R. H. L.

The growth action of sols of iron hydroxide, aluminum hydroxide, silicic acid and manganese peroxide. V. N. SIMAKOR. *Kolloid-Z.* 45, 207-30(1928).—Sols of $\text{Fe}(\text{OH})_3$, $\text{Al}(\text{OH})_3$, SiO_2 and MnO_2 were prepd. and the effect of electrolytes on their coagulation was studied. The first 2 have a pos. charge, while the latter 2 are charged negatively. The electrolytes used for coagulation were NaCl , BaCl_2 and Na_2SO_4 . The coagulation effect of a pos. on a neg. sol and the reverse action were studied both in the presence and absence of electrolytes. Dil. SiO_2 sol has a higher coagulation threshold than concd. sol. A sol. coagulating a mixt. of 2 oppositely charged sols does so in an additive manner in equiv. concn. Electrolyte greatly affects the reciprocal coagulation of oppositely charged sols.

RAYMOND H. LAMBERT

The viscosity change at the beginning of gelatinization of dilute agar-sols. H. G. BUNGENBERG DE JONG. *Rec. trav. chim.* 47, 797-818(1928).—The study of change from a sol to a gel has been made from viscosity measurements. The viscosity of a 1/1% agar sol increases steadily with time at 40° . A characteristic curve appears at lower temps. which is very pronounced at 35° . Two phases appear which may be de-

ected by the gelatinization curve, the first part of which is reproducible and rises steadily. A const. viscosity occurs after a time; then it again rises but in an erratic manner. This is explained by aggregation of particles which at first does not affect the mech. passage of material through a capillary but finally the particles become so large that errors are introduced. Electrolytes have a strong lyotropic influence at 0.2 *N* in the following series K_2SO_4 — KCl — KBr — KNO_3 — KI — $KCNS$, the last salt causing the least hydration. Ultramicroscopic examn. verifies the flocculation explanation.

RAYMOND H. LAMBERT

Relation between hydration and stability of sols and the bivalent nature of fluoride ions. S. GHOSH AND N. R. DHAR. *J. Indian Chem. Soc.* 5, 303–11(1928); cf. *C. A.* 22, 1512.—Sols have been classified as those in which viscosity decreases and surface tension and cond. increase on aging (i. e., become more hydrated), and those having the opposite tendency. The coagulation of $Zr(OH)_4$, $Cr(OH)_3$, and $Al(OH)_3$ by electrolytes has been studied and the pptn. values are greater for sols prepd. in the cold than in the hot. The difference is small for $Zr(OH)_4$ with the following increasing order for both sols: ferrocyanide > sulfate > oxalate > tartrate > fluoride > chloride > bromide > iodide. Additive amts. of KCl and K_2SO_4 are required to coagulate the sol. The order for coagulating $Cr(OH)_3$ or $Al(OH)_3$ prepd. either cold or hot is: sulfate > tartrate > oxalate > fluoride. Less electrolyte is necessary to ppt. either sol prepd. hot than in the cold. Stability is not assoc. with amt. of hydration. Jellies are formed more readily with $Zr(OH)_4$, V_2O_5 and $Ce(OH)_3$ than with $Fe(OH)_3$, $Cr(OH)_3$ and $Al(OH)_3$. Tendency to form jellies is connected with high degree of solvation and is therefore a good criterion of lyophile colloids. Fluoride ions act as bivalent ion ($F_2^{''}$).

R. H. LAMBERT

A contribution to the knowledge of activated silicic acid (silica gel). E. BEYL AND H. BURKHARDT. *Z. anorg. allgem. Chem.* 171, 102–25(1928).—The prepn. of 3 silica gels is described: one according to Patrick, another in which Na_2SiO_3 soln. was added to a mixt. of HCl and $NaCl$ and also the reverse at about 20° and finally repeating at about 5°. The heat of wetting for benzene and H_2O was detd. and activity was found to depend on degree of dryness of the gel after prepn. The absorption of crystal violet in a no. of liquid media was studied and only from tetralin did absorption take place strongly. Shaking greatly increases absorption. An isotherm of water vapor for silica gel as well as that of a mixt. of H_2SO_4 — H_2O is given at 13° for the various gels prepd. The absorption of I_2 from a hydrogel and a benzogel was studied. Drying at various temps. *in vacuo* and by alc., acetone and benzene shows that it is impossible to remove all the water. Silica gel was also made by addn. of aniline- HCl . The greater the diln. of materials, the greater is the porosity of the completed gel. The time of washing a gel plays an important role in activity. The aniline gel gives a far greater neg. vapor pressure on absorption of water than any other substance tested.

R. H. LAMBERT

An herapathite suspension. EMIL HATSCHKE. *Kolloid-Z.* 45, 195–7(1928).—Herapathite (quinine iodosulfate) was chosen for this study because it crystallizes from many solns. into single crystals and in many liquids it remains dissolved although it is decompd. The crystals are doubly refractive and very thin; giving purely linearly polarized light on transmission. Figures are given showing exceptional dichroism. At very low concn. of quinine no crystals are observed while supersatn. enters at high concn. Glycerol tetrachloroethane, tetrachloromethane and benzyl alc. were used as liquid media. Cellulose acetate and nitrate were tried as protective colloids; the former behaves like gelatin, changing from sol to gel on cooling below 40°. Violent shaking of the suspension causes it to acquire the optical properties mentioned.

R. H. L.

The electrokinetic potential of silicic acid gels. II. The influence of electrolytes. S. GLIXELLI AND J. WIERTELAK. *Kolloid-Z.* 45, 197–203(1928); cf. *C. A.* 22, 341.—The electrokinetic potentials of silicic acid gels measured in different ways do not give concordant data. Water is bound up in the gel on account of the presence of electrolytes. The potential drops with increasing concn. of acid for HNO_3 , HCl , H_2SO_4 , $H_2C_2O_4$ and H_3PO_4 and with decrease in valence of the acid radical. For the salts KNO_3 , $Ba(NO_3)_2$ and $La(NO_3)_3$ the potential is a linear function of concn., and decreases with valence of the cation. H^+ plays an important part on the elec. double layer. For inorg. salts the formula $\delta = a - k \log c$ is obtained, where δ is the electrokinetic potential, a and k are consts. and c is the concn. of electrolyte.

R. H. L.

Thermodynamic theory of the colloidal condition. A. MARCH. *Kolloid-Z.* 45, 97–112(1928); cf. *C. A.* 22, 3088.—A rigorous thermodynamic treatment is given to general colloidal systems. The energy, vol. and entropy of a disperse system are considered in terms of pressure and temp. where in thermodynamic equil. The disperse phase is imagined to be made up of particles of many sizes in a definite distribution. The surface tension is shown to be greater than 10 for particles greater than $r = 10^{-7}$

cm., shown by Ostwald and Hulett for the system $\text{CaSO}_4\text{-H}_2\text{O}$. The thermodynamics to electrolytic disson. and the influence of the elec. double layer on the stability of colloid systems are subjects discussed. The free energy of a protective colloid about particles of the disperse phase at equil. does not decrease steadily outward but passes through a sharp max. An explanation of coagulation is also given. The degree of dispersion of a suspensoid increases with increasing temp. and decreasing concn.

RAYMOND, H. LAMBERT

Permeabilities of colloidal substances to gases. KAZUO KANATA. Tokyo Imp. Univ. *Bull. Chem. Soc. Japan* 3, 183-8(1928).—The relative permeabilities of rubber, gelatin and celluloid for O , H , CO_2 , SO_2 and NH_3 have been detd. In the cases of celluloid and gelatin at least, the sorption of these substances are not adsorption phenomena. The mechanism of permeability and absorption is discussed. Conclusion: The permeability and hence the absorption is caused by the solution of gas in the colloidal substance.

A. L. HENNE

The ionic activity of gelatin. H. S. SIMMS. Rockefeller Inst. *J. Gen. Physiol.* 11, 613-28(1928).—Anions of ampholytes obey the modified Debye-Hückel equation. Gelatin solns. were titrated potentiometrically in the absence of salts and in the presence of NaCl , MgCl_2 , K_2SO_4 and MgSO_4 . From the data, the values of $S = v^2 - (v-1)^2$, where $v^2 = v^2 - (v^2 - v)r_s/18$, have been calcd. The max. and min. values of S with NaCl were used to calc. the mean distance (r_s) between like charges in gelatin. This distance is about 18 A. U. between acid or basic groups agreeing with the probable value. The data with NaCl are normal and obey the equation found to hold for simple, weak electrolytes. By using the NaCl data as a standard, the deviations produced by the other salts were calcd. and were also found to agree closely with those derived for simple, weak electrolytes. The deviations are related to the "apparent valences," i. e., values which are a function of the true valence and the distance between the groups. The "apparent valences" of gelatin are 2.4 for acid groups in alk. soln. and 1.8 for basic groups in acid soln. "The data indicate that gelatin is a weak multivalent ampholyte having distant groups and that the mol. has an arborescent structure with interstices permeated by mols. of the solvent and other solutes. The size and shape probably vary with the p_H ." The nature of the ionizable groups in proteins. *Ibid* 629-40.—Analysis of titration curves shows that gelatin contains acid groups with disson. indexes ($p_K = -\log K$) at p_H 2.9 to 3.5 corresponding with the amt. of dicarboxylic amino acids present. The acidic groups at p_H 9.4 in egg albumin agree with the amt. of tyrosine. The amts. of histidine and lysine in these 2 proteins agree with basic groups at p_H 6.1 and 10.4-10.6, resp. The quantity of arginine (p_H 8.1) in these proteins is considerably less than the amt. found on hydrolysis, the deficiency being compensated by a basic group at p_H 4.6. This basic group should be similar to aniline and cytosine, i. e., an amino group on a conjugated unsatd. (perhaps cyclic) system. The basic group at 4.6 is probably disrupted on hydrolysis, producing arginine. This prearginine has an important effect upon the properties of proteins, for otherwise the isoelec. point of gelatin would be 8.0 instead of 4.7 and that of egg albumin 6.6 instead of 4.8. Deamination of gelatin does not decrease prearginine, arginine and histidine groups but removes most of the lysine group.

C. H. RICHARDSON

Dialysis with stirring. M. KUNITZ AND H. S. SIMMS. Rockefeller Inst. *J. Gen. Physiol.* 11, 641-4(1928).—Substances to be purified are placed in collodion bags contg. a toy marble or a bubble of air, the bags then being stoppered and placed in glass tubes in a rocking machine. Distd. water is circulated around the bags while the machine is in motion. The rolling of the marbles or bubbles causes stirring making it possible to remove salts from protein solns. in 24-48 hrs. by this method.

C. H. R.

The effect of gelatin on the polymorphic transformation of mercuric iodide. JITSUSABURO SAMESEMA. Tokyo Imp. Univ. *Bull. Chem. Soc. Japan* 3, 189-91(1928).— HgI_2 contg. gelatin shows hysteresis of the transition temp., i. e., it is necessary to heat considerably higher than 127° to transform the red modification into the yellow one; on the other hand, the yellow modification remains unchanged for an indefinite length of time at room temp. Gelatin acts as a protective colloid in a solid phase. A lecture demonstration is described which shows the behavior of the protected supercooled HgI_2 . The transformation of the metastable form into the stable one is accelerated by light energy.

A. L. HENNE

Absorption of water by gelatin. II. The nitrate system. DOROTHY JORDAN-LLOYD AND WINIFRED BERTHA PLEASS. *Biochem. J.* 22, 1007-18(1928); cf. *C. A.* 22, 1078.—In acid swelling gelatin can absorb 70 times its own weight of water and still retain its cohesive properties. In alk. swelling the capacity for holding water in a jelly phase is of the same order. In salt swelling the capacity for holding water is only about half

salt appears to set in very rapidly, once a crit. water content has

solubility of poorly soluble salts. BENJAMIN HARROW. *KUNIO ANDO*. D. Biochem. Lab., *J. Biochem.* 9, 215-31 (1928).—The colloidal stability of poorly sol.

HgI, PbCrO₄, Cu₂Fe(CN)₆, ThFe(CN)₆, etc., was investigated.

but very sparingly sol., substances are classed as facultative col-

loids. The powder its elec. charge must be taken into consideration, but

expts. do not support the view that this is the most essential factor.

The cations:

are almost always more stable with an excess of anions than of

hydroxyl is more stable in an excess of KI than of KNO₃ soln. S. M.

of silver chloride and other sparingly soluble substances in gelatin.

A. C. CHATTERJI AND N. R. DHAR. *J. Indian Chem. Soc.* 5, 175-81 (1928).—In opposition to the common belief that sparingly sol. substances exist in a supersatd. condition in gelatin sol, a colloidal state is conceived. The cond. is lower and velocity of diffusion is far less than in cases of high ionization. The elec. cond. of various concns. of AgCl gelatin has been obtained. There is no sharp break in elec. cond. in passing from satd. to supersatd. soln. This is confirmed by others. E. m. f. measurements show Ag⁺ is present to about 40% of total Ag in soln. No definite relation between amt. of gelatin and non-ionic Ag exists.

R. H. LAMBERT

The empirical equation for gelation velocity. Studies on coagulation. II. KOZO HIRORO. Inst. Physiology, Kyoto Imperial Univ. *J. Biochem. (Japan)* 9, 103-15 (1928).—An empirical formula for gelation of gelatin, $\eta - \eta_1 = \mu/1 + (\mu/\lambda)t$, was confirmed at different concns. between 2.5 and 5.0% of Merck's powd. gelatin, the crit. concn. where $\lambda = \infty$ being 3.8%. The const. μ increases with the concn. of gelatin in a linear proportionality. The rate of increase is different in dil. and in concd. sol than at the critical concn., and is smaller than in the latter. Gelation of the agar-agar sol of 0.05 to 0.175% seems to bear a resemblance to the gelation of gelatin of low concns. The applicability of the empirical formula to this process has not been confirmed. The max. viscosity attained by gelation increases with the sol concn. Heating the sol at 98° gradually denatures it and reduces the max. viscosity.

S. MORGULIS

The conductivity method and proteolysis. II. An interpretation of the conductivity changes. HARRY D. BAERNSTEIN. Univ. Wisc. *J. Biol. Chem.* 78, 481-93 (1928); cf. *C. A.* 21, 3379.—There are 2 regions on the p_H scale in which the cond. changes and the amino N changes are identical in albumin digests. The changes in cond. produced by the addn. of ampholytes to HCl solns. may be quant. accounted for in some cases by the change in the H ion while in other cases the dicarboxylic acids must also be considered. It is questionable whether the Ag-AgCl electrode gives accurate results in Cl-ion detns. when protein materials are present because of the binding of the Ag ions by the protein. The H ions are probably bound in accordance with the mass law. Bjerrum's theory of ampholytic dissocn. apparently applies to one of the cases studied.

H. J. DEUEL, JR.

A new rock and a new rhythmic process in rock. Rhythmic ring formation. MAX STORZ. *Kolloid-Z.* 45, 231-8 (1928).—A study has been made of rhythmic banding in rock obtained from south Africa. Three classes are distinguished, i. e., coarse dispersions made of elastic sediment, colloidal dispersion called gelite and mol. dispersion or chem. sediment. The rock is about 94% SiO₂ and H₂O with a little over 2% Fe oxides. Photographs are given and a description follows of the growth of bands in the rock. The vivid coloring is due not to specific properties of color but to heterogeneous or chromolytic coloring as claimed by Ostwald. An explanation is given of the process of rhythmic formation which is believed to be a new discovery. A full explanation is given of 6 photographs included in the article.

RAYMOND H. LAMBERT

Secondary periodicity of Liesegang rings. B. DOGADKIN. *Kolloid-Z.* 45, 136-40 (1928).—The secondary periodicity obtained in Liesegang-ring formation cannot be explained by any theory so far proposed for primary Liesegang rings. By the use of small capillaries this phenomenon can be made more distinct and therefore can be more carefully studied. It is not characteristic of Liesegang-ring formation but must be explained by some synchronizing change in the ppt. formed. The soly. of the pptd. material is an important factor in the effect. Ag₂CrO₄ was specifically studied and an analysis of the Ag content was made by distance of diffusion. A typical diffusion curve is obtained. This is contrary to the wave-forming curve obtained for Liesegang rings. This secondary effect was also studied with respect to light action and was found to be absent when the system was protected from light.

R. H. LAMBERT

The dependence of internal pressures in solutions upon the nature of the dissolved substance. G. TAMMANN. *Z. anorg. allgem. Chem.* 174, 231-43 (1928).—T. discusses

the detn. of the effect of pressure upon the temp. of the max. supercooling, and the relations existing between the internal pressure and the concn. of the soln. ΔK is a measure of the attraction of the mols. of the dissolved substance for the solvent. The effect of the nature of the dissolved substance upon the concn. of the soln. is summarized, as follows: (1) For strong electrolytes the attraction of the mols. for those of the water is a complicated additive property, corresponding to their concn. in the soln. up to a concn. where n , the no. of moles dissolved in 1000 g. of water, is 1. The attraction of the individual ions is very different and decreases with the ionic vol. (2) Non-volatile, weak electrolytes or nonelectrolytes whose internal pressures are greater than those of water exhibit an attraction which is not essentially different from that of the electrolytes, but which may exceed that of the ions. Tables of ΔK values are given. (3) Volatile nonelectrolytes whose internal pressures are less than those of water, i. e., alc., show a complicated relationship between the mol. attraction and the concn. In dil. solns., the attraction of the mols. of the solute for those of the water may be smaller than that of the mols. for one another, giving a neg. ΔK value. With increasing concn., the attraction of the dissolved mols. for those of the water increases, the ΔK value passing through a min. However, if this min. is not observed the first additions of the solute have less effect upon the internal pressure than those of the following addns.

L. L. Q.

The variation of the temperature of the minimum volume of water as affected by the pressure compared with the variation of solutions as affected by the concentration. G. TAMMANN AND E. SCHWARZKOPF. *Z. anorg. allgem. Chem.* 174, 216-24 (1928).—The vol. isobars of water as detd. by Bridgman are discussed in connection with the effect of the concn. of various solutes as K_2SO_4 , Na_2SO_4 , H_2SO_4 , K_2CO_3 , Na_2CO_3 , $CaCl_2$, KOH and NH_3 , upon the change of the min. vol. of the soln. Graphs showing the relation between the temp. of the min. vol. and the concn., and between the temp. and the internal pressure are given. The t - p curves for Na_2CO_3 and $CaCl_2$ may possibly be in error. The relation between the temp. of the min. vol. and pressure seems to be linear up to 500 atm. The effect of supercooling while observations are being made is discussed for C_2H_5OH and HCl . The dilatometric method used is described briefly, as is the method of calcn. of results. The vol. isobars of solns. of $LiCl$, C_2H_5OH and HCl are given. The temps. of min. vol. are -57.5° for $LiCl$, -2.8 for C_2H_5OH and -12° for HCl .

L. L. Q.

Cryoscopic studies on the transition points of the compounds of organic solvents and salts. I. HAJIME OSAKA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 873-87 English Ed. I, 80-2 (1928).—To a known amt. of Me_2CO is added a sufficient amt. of salt (NaI) to form a satd. soln. and a solid phase, at a temp. 1° or 2° above the transition point (25.5°). The system is then supercooled; a crystal of the new phase ($NaI \cdot 3Me_2CO$) is added, and the highest temp. to which the thermometer rises is observed. It is then possible to calc. the cryoscopic const. for acetone. When mol. weights are to be detd. the lowering of the transition point is observed, instead of the customary lowering of the m. p. The following equation is to be used, in which the quantity

between parentheses represents the cryoscopic const. K : $\Delta T = \left(\frac{RT^2}{H} \frac{58.05}{100(c+i)} \right) \frac{100}{WM}$

where T = transition point, ΔT = the observed temp. lowering, R = gas const. H = heat of fusion of 1 mol. of the acetone compd., 58.05 = mol. wt. of Me_2CO , n = number of the Me_2CO mols. contained in 1 mol. of the compd., c = no. of Me_2CO mols. per mol. of salt in the satd. soln. at the transition point, i = the degree of dissocn. of the salt in the soln. plus unity, W = weight of Me_2CO , w the weight of the solute and M the mol. weight of the solute. Expts. with Me_2CO and NaI gave a cryoscopic const., $K = 24.0$, which was used for the mol. wt. detn. of naphthalene, camphor, benzoic acid and benzil by observation of the lowering of the transition point. Values were obtained within 4, 6, 1.5 and 2%, resp., of the theoretical values.

A. L. HENNE

Varying valency of platinum with respect to mercaptanic radicals. VII. PRAPULLA CHANDRA RAY, KSHITISH CHANDRA BOSE-RAY AND SACHINDRANATH RAY-CHAUDHURY. *J. Indian Chem. Soc.* 5, 139-47 (1928); cf. *C. A.* 22, 1922.—The action of benzyl sulfide on H_2PtCl_4 produces $PtCl_2 \cdot 2(PhCH_2)_2S$, $PtCl_2 \cdot 2(PhCH_2)_3S$ and $Pt_2Cl_4 \cdot 4(PhCH_2)_2S$. The first 2 have been subjected to the action of NH_3 , benzylamine, ethylenediamine, pyridine, aniline, dimethylaniline and piperidine, and the resulting products were analyzed. The compds. are mostly of the Werner type. In the absence of an ionizing solvent, the Cl outside the nucleus could not be shown directly to be ionizable, but it has been shown to be reactive by its action with bases. In $PtCl_4 \cdot 4NH_3$ both Cl atoms appear ionizable. The same is true for $PtCl_4 \cdot 4Py$. The methods of prepn. and identification are carefully described.

R. H. L.

The effect of salts on weak electrolytes. II. Calculation of overlapping constants. HENRY S. SIMMS. Rockefeller Inst., Princeton, N.J. *J. Phys. Chem.* 32, 1494-1515 (1928); cf. *C. A.* 20, 2774.—The potentiometric titration data of oxalic, malonic, succinic and azelaic acids are presented. The previously described method of calcg. titration indices of acids with overlapping consts. is reviewed. When a multivalent acid has titration consts. close together, the titration indices are correct only if the ionic strength is the same in all the exptl. points. A new method was devised for calcg. accurate titration indices from data with various ionic strengths R. L. DODGE

Activity coefficients and mass-action law in electrolytes. L. ONSAGER. Johns Hopkins Univ. *J. Phys. Chem.* 32, 1461-6 (1928).—The consideration of Soper (cf. *C. A.* 22, 1083), which lead to other limiting formulas for the activity coeffs. of electrolytes than those given by Debye and Hückel, are analyzed mathematically and shown to be erroneous. The fact that Soper's formulas agree better with the expts. considered by him is attributed to his applying the limiting square-root formulas at too high concns. R. L. DODGE

Extinction coefficient of mixtures of ferric chloride and organic acids in the ultra-violet as experimental evidence in favor of formation of unstable intermediate compounds. II. JNANENDRA CHANDRA GHOSH AND BHUPENDRA NATH MITRA. *J. Indian Chem. Soc.* 5, 191-202 (1928); cf. *C. A.* 22, 1899.—The intermediate products formed on photochem. oxidation of org. acids by ferric salts have been studied by measuring extinction coeffs. of the mixt. These coeffs. can be explained on the basis of an existing equil. due to the formation of loose complexes and that such complexes have a definite mol. extinction coeff. for each wave length. The concns. of such complexes have been calcd. from the data for the action of FeCl_3 on formic, acetic, propionic, oxalic, malonic, succinic, glycolic, lactic, tartaric, citric and mandelic acids. The range of concns. of the inorg. salt was so chosen that Beer's law would hold. The concn. of FeCl_3 was in most cases $\mu/1000$, although some data were collected at $\mu/3000$, where higher wave lengths could be measured. The value of K was assumed correct when extinction coeffs. could be reproduced. K diminishes as the mol. wt. in an homologous series increases. It increases, however, if a H atom of a CH_3 group is replaced by a COOH group. The same holds true if the H atom is replaced by an OH group. R. H. L.

Effect of electrolytes on the distribution of acetic acid between benzene and water. RAMPROSAD MITTRA. *J. Indian Chem. Soc.* 5, 209-19 (1928).—The partition of AcOH between C_6H_6 and H_2O and the influence of inorg. salts on the distribution have been studied. The salts used were NaCl , KCl , BaCl_2 , KNO_3 , K_2SO_4 , LiCl , $\text{Na}_2\text{C}_2\text{O}_4$, Li_2SO_4 , and Na_2SO_4 . Concns. of acid and salt were varied. E. m. f. measurements were made to obtain the change in activity of the H ion on addn. of neutral salts. Six tables of data are given which include calcd. ion strengths and concn. of acid in the 2 phases. Only a qual. discussion is given of the results since the quantity of acid in the benzene which obviously contains water is not accurately known. The neg. activation decreases in the order $\text{K} > \text{Na} > \text{Li}$ for sulfates and is probably present for all sulfates at sufficiently low concn. It is believed this neg. activation is due to the sulfate ion and that a pos. activation in a reverse direction occurs with the cation. Chlorides increase activation of the H^+ ion within the range studied, but it does not parallel activation of the AcOH mol. The agreement with the Debye equation is believed fortuitous and undissocd. mols. in aq. soln. are believed to exist. R. H. LAMBERT

Kinetic salt effect. I. The reaction between sodium monochloroacetate and sodium thiosulfate. A. N. KAPPANNA. *J. Indian Chem. Soc.* 5, 293-8 (1928).—The kinetics of the reaction between Na monochloroacetate and $\text{Na}_2\text{S}_2\text{O}_3$ have been studied at 50° , 60° and 70° and at various concns. The velocity const. increases with ion concn. in accordance with the theory of Brønsted. The temp. coeff. near 60° is 2. The activity coeff. does not change greatly between 50° and 70° but is much less than at 25° . Ten neutral salts have the following relative sp. effects with respect to ions: $\text{K} > \text{NH}_4 > \text{Na} > \text{Li}$ and $\text{Cl} > \text{NO}_3 > \text{SO}_4$. RAYMOND H. LAMBERT

The velocity of esterification of amides in alcohol. H. AUSTIN TAYLOR AND THOMAS W. DAVIS. New York Univ. *J. Phys. Chem.* 32, 1467-80 (1928).—The velocities of esterification of benzamide, formamide and acetamide were measured at 25° in dry and in aq. alc. solns., with HCl as a catalyst. The reactions indicate the kinetics of a bimol. reaction. Formamide possibly contains a tautomer that catalyzes its esterification. Small concns. of NH_4Cl or NH_4Br do not show any marked effect on the reaction velocity. Addn. of small quantities of water accelerates the reactions, a max. effect appearing between 8 and 12%. The acceleration is explained by assuming that a collision between alc. and amide mols. giving rise to an addn. compd.

precedes esterification. Water makes the crit. intermediate complex more unstable toward reactants than resultants. R. L. DODGE

Experiments on the electrocatalytic reduction of carbon monoxide. G. FOSTER AND M. SCHWAZAPPA. *Z. anorg. allgem. Chem.* 171, 163-7 (1928).—A "filter cathode" was used, consisting of a wire gauze covered with a thick layer of Ni powder through which gas could be bubbled. A diagram of the cell is given. The electrolyte was a mixt. of H_2SO_4 and $\text{H}_3\text{V}_2\text{O}_7$. HCHO , formed in small quantities, was the principal reduction product. Expts. without the Ni powder, with CO alone or mixed with H_2 and with NiSO_4 soln. as the electrolyte and other cathodes such as Cu, with or without Cu powder, Pb with or without Pb powder and nicked Pb, gave at most only traces of reduction products, among which HCHO could not be detected.

RAYMOND H. LAMBERT

The catalytic oxidation of carbon monoxide. IV. The pore volume of the catalysts manganese dioxide, copper oxide and mixtures of these oxides. HAL D. DRAPER. Univ. of Calif. *J. Am. Chem. Soc.* 50, 2637-53; cf. *C. A.* 17, 3824; 20, 2443, 3260.—The component oxides of a mixed catalyst retain their characteristic properties in mixts., and mixts. are more active catalytically than either pure component and thus the "mixture effect" is probably due to an acceleration of the electronic rearrangement postulated in the mechanism of catalytic reactions. Expts., completed in 1922, on the previously described catalysts deal with the pore vol. and related phys. properties. True d. and pore vol. of the catalysts were detd. by Hulett's immersion method (*C. A.* 14, 1073). No slow "drift" in the d. of the granules similar to that found with charcoal was noted, indicating either that there are very few small micro-capillaries or that the resistance to filling is less. Since compound formation is accompanied by a departure from linearity in the sp. vol.-compn. curve, the observed departure of 2% indicates the lack of any definite compd. being formed. Further indication of compd. formation by measuring the heat effects produced on mixing the oxides points to the same conclusions, as this was only 10 cal. per mole of 1 oxide. The observed enhanced porosity of the mixts. above that of the pure oxides is explained in terms of colloid-chem. phenomena. From the consideration of a theory of formation of the porous granule, a formula giving the vol. of water sorbed by a porous body in terms of the radius of curvature of the water surface corresponding to the equil. pressure of the water vapor, the no. and the radii and av. length of the capillaries of the solid, is derived. The slope of the vapor pressure-vol. curve is independent of the av. length of the capillaries and depends upon the no. and the radii of the capillaries present and the ratio of the satn. to the equil. pressure. Sorption curves on the catalysts show that the poorest catalysts have the finest-grained structure; the best, the ones with highest porosity and the smallest no. of fine pores and the largest no. of cavities. No explanation of the mixt. effect is offered. In the region of true adsorption all the curves except one coincide; this indicates that the ratio of surface exposed to pore vol. of granules is the same, in spite of the great difference in pore size.

ALBERT THOMAS FELLOWS

The influence of acids and bases on the inhibitory effect of gelatin upon the catalytic decomposition of hydrogen peroxide by colloidal platinum. H. V. TARTAR AND N. K. SCHAFER. Univ. of Washington. *J. Am. Chem. Soc.* 50, 2904-10; cf. *C. A.* 19, 2769.—This study of the influence of acidity and alk. on the inhibitory effect of gelatin upon the catalytic decompn. of H_2O_2 by colloidal Pt refutes Groh's (*C. A.* 9, 7) and Iredale's (*C. A.* 15, 2758; 16, 189) statement that the inhibitory effect of protective colloids is approx. proportional to their protective properties as measured by Zsigmondy's "gold number" and strengthens Tartar and Lorah's and Reinders' (*C. A.* 20, 1545) contention that the variation is in accordance with the known amphoteric character of the proteins. Bredig's Pt sol peptized with KOH was pipetted into 100-cc. flasks and isoelec. gelatin, acid or base added and dild. to 95 cc. and 5 cc. H_2O_2 added; 5-cc. portions of the reaction mixt. were removed and titrated at intervals in order to follow the course of the decompn., the H-ion concn. being detd. electrometrically. Results are expressed in terms of the half period and reaction const. from the unimol. formula were calcd. The results were excellently reproducible with alkalis and fairly so with acids. Time of dild. of the Pt and the duration of the catalysis must be controlled. Results with HOAc, H_2SO_4 and H_3PO_4 show that the inhibition increases rapidly to p_n 3.5-4 but beyond this point it constantly increases with HOAc, decreases with H_3PO_4 and first decreases and then increases with H_2SO_4 . This difference is attributed to the effect of the anions, as the inhibitory effect should increase to p_n 4.7; thus the inhibitory effect is not comparable to the protective effect. Data for KOH, NaOH, and $\text{Ba}(\text{OH})_2$ show that the OH ion is dominant in the catalysis, probably peptizing the Pt and directly decomposing the H_2O_2 . Careful standardization of the method is impera-

tive as the catalysis is influenced by the character and extent of the Pt surface and the concn. of the H_2O_2 .

ALBERT THOMAS FELLOWS

The new mass law. IV. The relation between the original mixture and the equilibrium mixture. RICHARD LORENZ AND P. WOLFF. *Inst. physik. Chem., Univ., Frankfurt a. M. Z. anorg. allgem. Chem.* 174, 181-70 (1928); cf. *C. A.* 21, 1743.—In studying condensed chem. systems, L. and W. classify equilibria upon the basis of the original compn. of the mixt. as follows: (1) Those having 2 constituents, a metal and a dissimilar salt. The relative amts. in both phases, the metal and the salt, are therefore defined by a detd. equil. (2) Those having 3 constituents, 2 metals and a salt, or 2 salts and a metal. The relative amts. in this case vary somewhat for a detd. equil. (3) Those having 4 constituents, 2 metals and 2 salts, where again the relative quantities are variable. L. and W. consider this case as superfluous. These classifications are explained by means of mathematical and graphical schemes, with various mixts. of Sn, $SnCl_2$, $CdCl_2$ and Cd as examples. The discussion as presented by L. and W. applies only to those systems in which equil. is reached without a change in the total no. of atoms or mols.; that is, the same no. of metal atoms will react as salt mols. in causing the equil. The no. of the different atoms and mols. present at equil. will depend upon the original quantities used and the nature of the constituents. L. and W. picture the method of reaching equil. by saying that the point which represents the original mixt. and which lies either at the corner or on the side of the graph, depending on the no. of constituents, moves in a straight line toward the point of equil. with a momentary velocity as detd. by the quantity and nature of the original materials used, at a const. temperature. Therefore the equiv. points lie upon the diagonals of the square. The reaction is more complicated, however, because of the formation of metal clouds. This effect exerts a min. effect and may be disregarded. The system $2Tl + CdCl_2 \rightleftharpoons Cd + Tl_2Cl_2$ is given as an example of an equil. in which the metathesis is represented by equiv. quantities rather than by equal quantities of atoms and mols. The systematic method of studying the system $Sn + CdCl_2 \rightleftharpoons Cd + SnCl_2$ is described. V. The mole number and the position of the equivalence point. RICHARD LORENZ AND GEORG SCHULZ. *Inst. physik. Chem. Univ., Frankfurt a. M. Ibid* 171-8.—Whether equations for equilibria involving substances which may be assocd. should be written as $Pb + 2AgCl = 2Ag + PbCl_2$ or $Pb + Ag_2Cl_2 = 2Ag + PbCl_2$ and $2Tl + CdCl_2 = Cd + 2TlCl$ or $2Tl + CdCl_2 = Cd + Tl_2Cl_2$ is discussed briefly. Graphs are given which compare the ideal equilibria curves, from the ideal mass law $(x/1-x) \cdot (1-y/y) = C$, with actual curves which follow the new mass law expression $(x/1-x) \cdot (1-y/y) = Kx^a$, where $u = f(x, y, a, b)$, where x and y refer to the mole fraction of the metal phase and salt phase, resp., and a and b refer to the van der Waals consts. Reactions of the following types are discussed: $A + B \rightleftharpoons C + D$; $A + 2B \rightleftharpoons C + 2D$; $A + B \rightleftharpoons C + 2D$. The method of detg. the locus of the equivalence point for these equations is given. It is not possible to conclude what the position of the equivalence point will be from the number of mols. entering into a reaction.

L. L. Q.

A homographical method for converting percentage by weight into atomic percents for ternary systems. O. REDLICH. *Z. anorg. allgem. Chem.* 174, 285-9 (1928).—R. indicates by means of simple mathematical equations and graphs, a method of converting the percentage by weight of the constituents of a ternary system into at. percents.

L. L. Q.

An explanation of the phase rule. O. REDLICH. *Z. anorg. allgem. Chem.* 174, 281-4 (1928).—R.'s explanation is summarized as follows: (1) For the identity of 2 closed systems, which are in equil., a similarity in the quantities, by weight, of the components, is a necessary condition, as well as total energy and total vol. (2) Those cases only shall be considered in which this condition regarding the components is satisfied, and in which it is assumed that all cases are included which are in complete equil., and which are not acted upon by any outside forces except that due to the pressure of the surrounding walls. (3) The quantities by wt. of the phases are independent of one another. (4) There is no relation between the quantities of phases and the intensive properties. These relations are expressed mathematically, and the usual phase rule expressions derived therefrom.

Equilibrium diagram of the system: antimony-arsenic. QASIM ALI MANSURI. Aligarh Muslim Univ., Aligarh, India. *J. Chem. Soc.* 1928, 2107-8.—By the method of thermal analysis this system, up to 80% As, is shown to consist of 1 series of solid solns. with a min. m. p. of 805° at 13% As.

JAMES M. BELL

Polyiodide equilibrium in aqueous and salt solutions. JOHN S. CARTER. Univ. Leeds. *J. Chem. Soc.* 1928, 2227-30.—From soly. measurements at 25° of I in aq. solns. of NaI and in aq. solns. of NaI contg. Na₂SO₄, the values of $K = \frac{[I_2][I_2]}{[I_3]}$ have been detd. on the assumptions that the only polyiodide is the triiodide, that the iodide and triiodide have no influence on the soly. of I as such, and that both salts are completely ionized. Although the values of K are not const., they are approx. the same for the 2 series at similar concns. of NaI. This agreement is much closer than would be anticipated from the activity theory. The data indicate the presence of polyiodides more complex than the triiodide in the more concd. solns. J. M. B.

Solutions. I. Freezing-point diagrams and latent heats of evaporation of binary mixtures of volatile liquids. WILFRED F. WYATT. Univ. Sheffield. *Trans. Faraday Soc.* 24, 429-38(1928).—F.-p. diagrams are found for the systems: (I) acetone-CHCl₃, (II) EtOH-CCl₄, (III) EtOH-C₆H₆, and (IV) C₆H₆-CHCl₃. In I an equimol. compd. is formed, m. -99.5°. In II a transition point occurs at 44.6% of CCl₄, temp. -47.6°. In III there is no transition point but the curve is displaced to the alc. side. A normal curve was found for IV. The solids sepg. were isolated and analyzed, and extended series of solid solns. are indicated. The transition point in II is due to conjugate solid solns., with a difference in mol. concn. at the transition point of about 5%. To investigate mol. forces in these binary mixts., preliminary considerations of latent heats are presented. Plotting internal mol. heat against concn. shows marked changes of slope in the first three cases. For I there is a similar change of slope when molal heat capacity is plotted against mol. concn. JAMES M. BELL.

Heat capacity at low temperatures of zinc oxide and of cadmium oxide. RUSSELL W. MILLAR. Pacific Exp. Sta., U. S. Bur. Mines, Berkeley, Calif. *J. Am. Chem. Soc.* 50, 2653-6(1928).—The heat capacities of ZnO and CdO from 70° to 300° abs. are detd. Calcns. from these values give the entropy at 298° abs. of ZnO as 10.28 cal. per degree, and of CdO as 13.17 cal. per degree. At this temp. ΔH for ZnO is -83130 cal. and for CdO ΔH is -54200 cal. JAMES M. BELL.

Surface energy of solid sodium chloride. III. The heat of solution of finely ground sodium chloride. S. G. LIPSETT, F. M. G. JOHNSON AND O. MAASS. McGill Univ., Montreal, Canada. *J. Am. Chem. Soc.* 50, 2701-3(1928). The heat of soln. of finely divided salt, a . . diam. of particles 1.3 μ , is 25 to 40 cal. less, numerically, than the heat of soln. of coarse salt at the same temp. and concn. Calcns. for the heat of soln. of sublimed salt of the same av. particle size give a heat of soln. only 11 cal. less than that of coarse salt. The difference is probably due to the uneven surface of the finely ground salt, giving a larger surface area than for the sublimed salt which appears definitely cubic when examd. under a microscope. JAMES M. BELL.

The heat of dissociation of oxygen as estimated from photochemical ozonization. OLIVER R. WULF. Univ. of California. *Proc. Natl. Acad. Sci.* 14, 614-7(1928). The heat of dissocn. of O₂ has been estd. by Warburg (cf. *C. A.* 14, 1637), as 138,000 cal. and by Born and Gerlach (cf. *C. A.* 16, 873), as 162,000 cal. W. believes that the latter est. rests upon a mistaken assumption. A recent study of the existing data on the absorption of light by gaseous and liquid O indicates that the est. of Warburg's is likewise in error in that it pertains probably to the mol. O₂, a polymer of O₂, rather than to O₂. If this is so, the true heat of dissocn. is lower than the value now generally accepted. R. I. DODGE.

Physical methods in the chemical laboratory. V. Production and measurement of high temperatures. ERICH SCHROER. *Z. anorg. Chem.* 41, 757-60(1928).—A review with up-to-date compilation of the German literature. **VI. Production and measurement of low temperatures.** MARTIN RUHEMAN. *Ibid.* 44, 50-51.—A review of the production of low temps., gas liquefaction, the adsorption process and low-temp. measurements, with 28 references almost exclusively German and Dutch.

The applicability of resonance methods for determination of dielectric constants of conducting liquids. HEINRICH KNIEPKAMP, Berlin. *Z. Physik* 51, 95-107(1928). Attempts were made to det. dielec. consts. of sugar and urea solns. by resonance methods. An inductionless shunt across the capacity in an oscillating circuit showed the position of current resonance depended on the shunt. This was not the case for potential resonance. The latter method has decided advantages for measuring the dielec. consts. of weakly conducting liquids. Measurements were made at various concns. with a wave length of 530 m. G. B. TAYLOR.

The absolute zero of internal energy and entropy, and the corresponding inertness of matter. R. D. KLEEMAN. *Science* 68, No. 1758, 235-6(1928).—The first and second differential coeff. with respect to the temp. of the internal energy, pressure and

vol. of a condensed substance are zero at $T = 0$ either at const. pressure, vol., or at equil. pressure. Matter thus possesses a remarkable inertia to temp. changes at $T = 0$. This suggests that at $T = 0$ an atom differs considerably from what it is at higher temps., this difference being no doubt assocd. with change of electronic configuration. This is in accordance with M.'s deduction (C. A. 21, 2416) that at $T = 0$ the internal heat of vaporization L is zero and that a substance in the gaseous state at $T = 0$ possesses an abnormally large sp. heat which may amt. to thousands of cal. per g. These results may be explained by supposing that during evapn. an atom undergoes a change in electronic configuration which gives rise to a decrease in internal energy equal to the work done against the at. forces of attraction and that on heating the vapor an approx. equal increase of internal energy takes place with corresponding reversal of electronic configuration.

F. R. BICHOWSKY

The entropy of vaporization of unassociated liquids. JOHN CHIPMAN. Georgia School of Technology. *J. Phys. Chem.* 32, 1528-31(1928).—The empirical equation of Trouton, Nernst, Bingham, Forcrand, Kistiakowsky and Mortimer expressing the heat of vaporization as a function of the b. p. are compared. The equation of Kistiakowsky (I), $\Delta S = R \ln V$ (where V is the natural log. of the mol. vol. of the vapor in equil. with the liquid) is found to be valid over a wide range of temp. for unassocd. liquids. By calcg. the entropy of vaporization to a concn. of 0.00507 moles per l. for a no. of gases and solids it is found that I is less reliable at lower temp. than at the b. p. By subtracting I from Sackur's equation for the entropy of a monatomic gas, where $S = R \ln (T^{3/2} H^{3/2} V) + C$ an expression is obtained by which the entropy of a monoat. liquid in the neighborhood of its b. p. may be roughly estd. since $S = \frac{1}{2} R \ln (TW) + C$.

D. H. POWERS

Quinhydrone electrode. F. J. MAFFEI. Polytechnic School of S. Paulo. *Bol. soc. chim. S. Paulo* 1, 61-6(1928). The colorimetric method for the detn. of H-ion concn. is simple, convenient, but is not very sensitive; the natural color of the soln. interferes, and salts and protein matter are not without action. The potentiometric method, with the H ion electrode, though more sensitive, is not very convenient, since time is required before equil. is set up between soln. and electrode, and the electrode is influenced by O, by reducers and by unsatd. substances necessitating special app. to obtain pure H. Hence the quinhydrone electrode deserves attention. Haber, Russ, Granger and Nelson have shown that in an aq. soln. of benzoquinhydrone the dissocn. can be represented by: $C_6H_4(OH)_2 \rightleftharpoons C_6H_4O_2 + 2H^+ + 2(-)$. An electrode of Pt or Au is placed in the soln. and acts as a H electrode, the potential being $E = E_0 + (K/2) \log [C_6H_4O_2 / C_6H_4(OH)_2] + K \log [H^+]$. This may be written $E = E_0 + K \log [H^+]$ or $\log 1/[H^+] = p_H = (E - E_0)/K$. Working against the calomel or satd. KCl electrode the expression becomes $\log 1/[H^+] : p_H = (0.4557 - 0.00028 t - E)/(0.0541 + 0.00021)$. Billman preps. the soln. to be used thus: a soln. of 100 g. Fe NH₄ alum in 300 cc. water is added to a soln. of 25 g. hydroquinone in 300 cc. water, and cooled, filtered and washed 4 or 5 times. LaMer and Parsons concluded that the quinhydrone electrode is a satisfactory substitute for the H electrode as long as an alky. of p_H of 8 is not exceeded and oxidants and reducers are absent. Autoxidation must be guarded against. Subsequent work confirms the statement that at 18° the quinhydrone electrode gives good results in solns. whose p_H is less than 8 though near $p_H = 7$ the results may be a little low. Cullen and Billman and also Grossman used the quinhydrone electrode for blood. Schaefer and Schmidt use it for gastric juices, the cerebrospinal fluid and urine. Kolthoff found errors in the presence of proteins, Harris used the electrode for amino acids, Wegner and McGill for alkaloids and Watson for sugar liquors. A bibliography is given of 24 references mostly in English, French and German.

The influence of electrostatic fields on the dielectric constants of bodies in nematic phase (liquid crystals). MIECZYSLAW JEZEWSKI. *Phys. Inst., Cracow. Z. Phys.* 51, 159-64(1928).—Dielec. consts. of *p*-azoxyphenetole and *p*-azoxyanisole were measured in fields from 0 to 1000 v. per cm. at various temps. The dielec. consts. decrease with applied voltage at all temps. until a temp. was reached where only the amorphous phase of the substance existed. Here the decrease with field strength was insignificant.

G. B. TAYLOR

Experimental proof of negative dispersion. H. KOPFERMANN AND R. LADENBURG. Kaiser Wilhelm Inst. f. phys. Chem. u. Elektrochem., Berlin-Dahlem. *Nature* 121, 1-8-9(1928).—By considering the dispersion of a gas in the neighborhood of an isolated spectral line, a formula is derived for the change in n . This formula contains a term for the "negative dispersion" effect. This term is considerable if the gas is excited strongly and if the difference of energy between the 2 quantum states is not too large.

Such "negative" dispersions" have been found experimentally when Ne is electrically excited by c. ds. beyond 100 milliamps. per sq. cm. JAMES M. BELL

The action of salt mixtures on copper. A. LAUNERT. *Compt. rend.* 187, 206-7 (1928); cf. Peczalski (*C. A.* 19, 2022).—L. heats Cu rods 3.55 cm. in diam. and 20 cm. long in the presence of the pure KCl, BaCl₂, and SrCl₂, and their 3 binary mixts. in various proportions, and measures the resistance and diam. of the rods at temps. below the eutectic point of the pairs of salts. Conclusion.—The slight variations observed can be explained by the absorption of salt vapors by the metal. G. CALINGAERT

GUÉRIN, GEORGES: Osmose, dialyse, ultrafiltration. Paris: Dunod. Reviewed in *Tiba* 6, 1199(1928).

Physical methods in chemical laboratories. VII. The significance of spectroscopy for chemical investigation (2nd Part). EUGEN RABINOWITSCH. *Z. angew. Chem.* 41, 1021-8(1928); cf. *C. A.* 22, 4017. W. C. EBAUGH

Testing the Schrödinger theory. J. L. SNOEK, JR., AND L. S. ORNSTEIN. *Z. Physik* 50, 600-8(1928).—Absorption of lines in the Balmer spectrum of H is measured in the fine structure of H α and H β by means of an echelon spectroscope and the method of photographic photometry. The ratio of the total absorption of H α to H β is found to be in satisfactory agreement with the theoretical value, 5.37. W. F. MEGGERS

The propagation of Schroedinger waves in a uniform field of force. G. BREIT. Dept. of Terrestrial Magnetism, Carnegie Institution of Washington. *Phys. Rev.* 32, 273-6(1928).—The phase-difference between a Schroedinger wave refracted by a uniform field of force and the primary wave is calcd. The results are shown tabularly and graphically. As the wave length increases, the phase difference decreases, reaches a min., and then increases again. It is suggested that the intensity of some crystal reflections should vary anomalously as a result. BERNARD LEWIS

The structure of acetylene. JARED K. MORSE. Univ. Chicago. *Proc. Natl. Acad. Sci.* 14, 645-9(1928).—Since C₂H₂ can be considered as an C₂H₄ mol. (*C. A.* 22, 1879) from which 4 H atoms have been removed and since the infra-red bands have recently been analyzed, it is possible to write down the coordinates of the dynamic isomers of C₂H₂, compute the moments of inertia of these structures and compare them with the moments of inertia obtained from the band spectra analysis. The moment of inertia of 2.5 $\times 10^{-39}$ g. sq. cm. which represents the moment of inertia of the most abundant of the dynamic isomers calcd. on the basis of the model presented in the paper from abs. values of the radius of the C atom (diamond) and the length of C-H bond (solid C₂H₆) obtained from x-ray expts. is in remarkable agreement with the value 2.4 $\times 10^{-39}$ g. sq. cm. obtained by Levin and Meyer by means of the quantum theory from the analysis of the infra-red absorption bands of gaseous acetylene. MARIE FARNSWORTH

The assignment of quantum numbers for electrons in molecules. I. ROBERT S. MULLIKEN. Washington Square Coll., New York Univ. *Phys. Rev.* 32, 186-222 (1928).—The problem of making a complete assignment of quantum nos. for the electrons in a (non-rotating) diatomic mol. is considered. A tentative assignment of such quantum nos. is made in this paper for most of the known electronic states of diatomic mols. composed of atoms of the first short period of the periodic system. The assignments are based mainly on band-spectrum and to a lesser extent on ionization-potential and positive-ray data. The methods used involve the application and extension of Hund's theoretical work on the electronic states of mols. Although the actual state of the electrons in a mol., as contrasted with an atom, cannot ordinarily be expected to be described accurately by quantum nos. corresponding to simple mech. quantities, such quantum nos. can nevertheless be assigned formally, with the understanding that their mech. interpretation in the real mol. (obtained by adiabatic correlation) may differ markedly from that corresponding to a literal interpretation. With this understanding, a suitable choice of quantum nos. for a diatomic mol. appears to be one corresponding to an atom in a strong elec. field, namely, quantum nos. n , l , σ , and s , ($s_r = 1/2$ always) for the r th electron and quantum nos. s , σ_1 , and σ_2 for the mol. as a whole (σ_1 and σ_2 represent quantized components of l , and s , resp., with reference to the line joining the nuclei). These quantum nos. may be thought of as those assoc. with the imagined "united atom" formed by bringing the nuclei of the mol. together. A notation is proposed whereby the state of each electron and of the mol. as a whole can be desig-

nated, e. g., $(1s)^2 (2s)^2 (2p)^2$, 3P for a seven-electron mol. with $\sigma_1 = 1$, $s = 1/2$, in a symbol such as $2s^2$ the superscript denotes l , the main letter, σ_1 , thus $2s^2$ means that the electron in question has $l = 2$, $l = 1$, $\sigma_1 = 0$. Electrons with $\sigma_1 = 0$, 1, 2,—are referred to as s , p , d —electrons. It is shown that in a mol. it is usually natural to define a group of equiv. electrons giving a resultant $\sigma_1 = 0$, $s = 0$ as a *closed shell*; in this sense, two s electrons, or four p , or d , f —, electrons form a *closed shell*. The possible mol. states corresponding to various electron configurations are deduced by means of the Pauli principle. Electrons which undergo an increase in their n values (principal quantum nos.) when atoms unite to form a mol. (Hund) are here called *promoted electrons*. The electrons in a mol. may be classified according to their *bonding power*, positive, zero, or negative. Electrons whose presence tends to hold the mol. together, as judged by the fact that their removal from a stable mol. causes a decrease in the energy of dissociation D or an increase in the equil. internuclear sepn. r_0 may be said to have *positive bonding power*, and are identified with, or defined as, *bonding electrons*. Bonding power in terms of changes of D and of changes of r_0 are distinguished as "energy-bonding-power" and "distance-bonding-power." On the whole, promoted electrons should tend to show negative energy-bonding-power, unpromoted electrons positive energy-bonding-power, but much should depend on "orbit dimensions." Certain rules governing the relations of the electronic states of a mol. to those of its dissociation products are discussed; in addn. to theoretical rules established by Hund in regard to σ_1 and s values, another rule is here proposed, namely, that the σ_1 values of all the at. electrons before union should be preserved in the mol. (σ_1 conservation rule). Selection rules for electronic transitions are also discussed; in addn. to rules given by Hund, the following are proposed: $\Delta l = \pm 1$ for intense transitions: $\Delta \sigma_1 = 0, \pm 1$. *Results*.—The key to the assignment of quantum nos. made here is found in the fact that the mols. BO , CO^+ and CN show an *inverted* 3P state instead of the normal 3P which should occur if this state were analogous to the ordinary 3P states of the Na atom. The existence of such a low-lying inverted 3P indicates that in these mols. there exists a closed shell of p electrons from which one is easily excited. It is concluded that this is a $(2p)^4$ shell. The identification of 2 other closed shells, of s electrons, very likely $(3s)^2$ and $(3s')^2$, follows; the electrons in these and the $(2p)^4$ shell are roughly equal in energy of binding. According to this interpretation, the electron jumps involved in the band spectra of BO , CN , CO^+ and N^+ are more analogous to x-ray than to optical electron transitions. From this beginning, proceeding to CO , N_2 , O_2 , O_3^+ , F_2 , C_2 , etc., a self-consistent assignment of quantum nos. is built up for most of the known states of the various mols. treated in this paper. The spectroscopic analogies of CN , N_2 , NO , etc., to Na , Mg , Al are justified and the partial failure of these analogies such as the chem. resemblance of CN to a halogen, are explained. Nearly all the hitherto observed ionization potentials of the mols. discussed can be accounted for by the removal of a *single* electron from one or another of the various closed shells supposed to be present. The N_2^+ band fluorescence produced by short wave-length ultra-violet light (Oldenberg) is accounted for as the expected result of photo-ionization of a $3s^2$ electron. The steadily decreasing heat of dissociation in the series, $N_2 - NO - O_2 - F_2$, is accounted for by the successive addn. of promoted $3p^2$ electrons with strong neg. bonding power. Starting from N_2 , whose normal state corresponds to a 1S configuration of closed shells, we add one $3p^2$ electron to give the 3P normal state of NO , and O_2^+ , two to give the 1S normal state of O_2 , four to give a closed shell, $(3p)^4$, which accounts for the 1S normal state of F_2 . In N_2 (probably also in O_2 and the other homopolar mols.) band systems for which $\Delta l \neq 1$ are notably lacking, thus giving support to Hund's predicted selection rule for homopolar mols., in the analogous heteropolar mol. CO , many systems occur with $\Delta l = 0$ than those for which $\Delta l = \pm 1$. On account of this strict selection rule in N_2 certain levels should be metastable, in particular the final level of the α afterglow bands of *active nitrogen*. There is evidence for the existence of a strict selection rule $\Delta s = 1$ in homopolar mols.

BERNARD LEWIS

Artificial disintegration by means of alpha particles from polonium. HANS PETERSSON. Radium Inst., Vienna. *Arkiv Mat. Astron. Fysik* 21A, No. 2, 11 pp. (1928).—Since the α -rays from Po are sufficiently powerful to cause disintegration, Po is a more convenient source of radiation than the shorter-lived $Ra C$. From an investigation on the disintegration of C by means of α -particles from Po , it is shown that only with α -particles of a range less than 2 cm. no at. fragments of retrograde direction are observable from this element by the scintillation method. These results are contrary to the results of Bothe and Fränz (*C. A.* 22, 1902), who are not able to disintegrate C with Po .

MARIE FARNSWORTH

The artificial disintegration of atoms and their packing fractions. HANS PETERSSON.

son. Radium Inst., Vienna. *Arkiv Mat. Astron. Fysik* 21A, No. 1, 16 pp. (1928).—Starting from the assumptions that mass and energy are equiv., and that to each kind of stable atom must be ascribed a definite at. mass agreeing with the values found by Aston's precision measurements, the mass-energy balance for various hypothetical disintegration processes is worked out. It is found that, from an energy point of view, the simple release of a proton from the C or from the O nucleus by means of α -particles from Ra C is not compatible with Aston's measurements. If, on the other hand, the release of an H-particle is supposed to involve also the capture of the α -particle by the residual nucleus as has been found to be the case with certain light elements, the disintegration of C and O is compatible with Aston's measurements. Also, with an analogous nuclear synthesis between a Br nucleus, Br₇₆ and a colliding α -particle forming a nucleus of Kr₈₂ with a proton escaping, a positive mass energy balance is found, indicating that this process should be possible. On the other hand, the same reasoning applied to bombarded He shows that the fraction of the kinetic energy of an α -particle from Ra C which is available for disintegration work at its collision with a free He nucleus is much too small to cover the neg. mass energy balance involved in the ensuing synthesis of a Li₇ nucleus and a free proton, indicating that this kind of He disintegration is not possible. From the general validity of the whole-no. rule with the heavier elements and their isotopes, inferences are drawn which run against the assumption that the He nucleus is the dominant subnuclear unit. With regard to the supposed compn. of the C and the O nuclei from He-subnuclei only, it is shown, that the excess of packing responsible for keeping these together is less than the mass equiv. of the kinetic energy available for disintegration work at their collision with an α -particle from Ra C. Hence, granted the existence of subnuclear He⁺⁺ units within these at. nuclei, the release of a secondary α -particle and residual C nucleus from an α -bombarded O atom ought to be possible as well as the complete disintegration of C into He by the same means.

MARIE FARNSWORTH

The energy output of the β recoil of thorium B. I. WERTENSTEIN. Radiologische Lab. der Warschauer Wiss. Ges., Warsaw. *Z. Physik* 40, 463 (1928).—Answering the criticism of K. Donat and K. Philipp (cf. C. A. 22, 538), W. recalls the exptl. conditions in which his collaborator A. Muszkat performed her work, and shows that the results of D and P. do not contradict M.'s results and are perfectly compatible with them.

A. L. HENNE

The γ -ray spectrum of protoactinium and the energy of the γ -rays accompanying α - and β -ray transformation. LISE MEITNER. *Z. Physik* 50, 15-23 (1928).—In the γ -ray spectrum of Pa 3 rays of wave lengths 130, 41.9 and 38.2×10^{-11} cm. have been detected by the method of deflecting β -particles in a magnetic field. A comparison of the γ -rays of Ra B, Ra C, Ra D, Th B, Th C, Pa, RdAc and Ac X, shows that (1) if they accompany β -ray emission variations in the radiated energy as great as 1 to 50 exist, whereas if the γ -rays accompany the emission of α particles the radiated energies are all approx. the same; (2) of the elements of a series emitting α -particles the one of longest half-period emits the γ -ray of greatest energy, and of the elements of a series emitting β -particles the one of shortest half period emits the γ -ray of greatest energy.

C. C. KIESS

Note on thermionic emission. LEWIS TONKS. General Elec. Co., Schenectady N. Y. *Phys. Rev.* 32, 284-6 (1928).—Electron emission expts. can throw light on the surface heat of charging only if the density of electrons in equil. with an emitting surface is the same whether evapn. occurs with const. surface charge or with surface charge equal (and opposite in sign) to evapn. charge. This equality is proved thermodynamically in the present note.

BERNARD LEWIS

The critical potentials of metallic vapors: I. Copper. H. B. WAHLIN. Univ. of Wisconsin, Madison, Wis. *Phys. Rev.* 32, 277-83 (1928), cf. C. A. 22, 533. By using a method for detg. the crit. potentials of metallic vapors in which the vapor is produced in the neighborhood of a gauze by vaporization of the gauze, it has been found possible to det. a no. of crit. potentials in Cu vapor in the region 0 - 20 v. The values found in the region 0 - 11 v. can be identified from the spectroscopically known energy levels. The interpretation of those above 11 v. is incomplete. Some of them agree with certain soft x-ray levels, and some with second ionization potentials. Whether the remaining levels correspond to spark terms or not remains to be seen.

BERNARD LEWIS

Oscillations in ionized gases. IRVING LANGMUIR. Gen. Elec. Co. *Proc. Natl. Acad. Sci.* 14, 627-37 (1928).—In strongly ionized gases at low pressure, e. g., in the Hg arc, the free electrons have a Maxwellian velocity distribution corresponding to temps. that may range from 5000-60,000, although the mean free path of the electrons may be so great that ordinary collisions cannot bring about such a velocity distribution.

Electrons accelerated from a hot cathode, which originally form a beam of cathode rays with uniform translational motion, rapidly acquire a random or temp. motion which must result from impulses delivered to the electrons in random directions. Such scattering might be caused by elec. oscillations of very high frequency and of short wave length. Oscillations with amplitude less than 0.2 v. and frequencies up to 1.2×10^9 have been observed. These oscillations are discussed from a math. and phys. viewpoint.

MARIE FARNSWORTH

Reflection and refraction of electrons by a crystal of nickel. C. J. DAVISSON AND L. H. GERMER. *Bell Tel. Labs. Proc. Natl. Acad. Sci.* 14, 630-27(1928); cf. *C. A.* 22, 4354.—If a homogeneous beam of electrons is directed against a 111-face of a Ni crystal at various angles of incidence, in which observations are made on the intensity of scattering in the plane of incidence as a function of bombarding potential and direction, it is found that the incident beam of electrons is regularly but selectively reflected from the crystal face. At a given angle of incidence the reflected beam is observed whenever the speed of the incident electrons is comprised within any of certain ranges, and within each of these ranges the intensity of the beam is characterized by a sharply defined max. The phenomenon is interpreted as a wave-mechanics analog of the regular selective reflection of monochromatic x-rays from a crystal face. Contrary to the results found for x-rays, the intensity of the reflected beam is not a max. when the wave length of the incident beam satisfies the Bragg formula; and the wave length of the beam of the scattered electrons as calcd. from the de Broglie formula is never the same (except in a special case) as that of the corresponding beam of x-rays. Reasons for these discrepancies are discussed.

MARIE FARNSWORTH

The velocity distribution of photoelectrons produced by soft x-rays. E. RUDBERG. King's Coll., London. *Proc. Roy. Soc. (London)* A 120, 385-422(1928).—A special method of magnetic analysis was used to det. the distribution of velocity among the photoelectrons produced in solid conductors by soft x-rays. This depended on the application of a variable magnetic field to prevent the electrons of low velocity from reaching a cylindrical electrode. Data are given for the electron emission from Ag, Cu, Al, C and a transparent Ag film deposited on quartz. In all cases the emission consisted of 1 group of electrons with energies corresponding to a few v., and a much smaller group having energies chiefly in the region 200-280 v. The first group is reduced by about 50% by baking the targets at 400°. The second group is not appreciably affected by this treatment. Unlike the other metals, Al did not show any reduction of the first group on heating. It is suggested that the second group of photoelectrons, which has about the same magnitude for all the metals except Al, consists of fast primary electrons produced directly by the incident radiation and that the group of slow-moving electrons is the secondary emission resulting from the presence of rapidly moving electrons in the target. The energy distribution among the fast electrons is satisfactorily accounted for by assuming an incident radiation consisting of the C K α line. The distribution of energy among electrons of the first group compares well with the data of other investigators for the secondary emission produced by electrons of corresponding energy. The energy distribution in the secondary emission is to some extent detd. by energy losses in the target before they escape. Preliminary measurements indicate an absorption coeff. of 3×10^5 /cm. for the radiation used in this work.

A. W. K.

The dielectric constant of air at radio frequencies. A. B. BRYAN AND I. C. SANDERS. The Rice Inst. *Phys. Rev.* 32, 302-10(1928).—A radio-frequency method has been used to measure the dielec. const. K of dry air free from CO₂, the value obtained being 1.0005893 for standard conditions of temp. and pressure. The probable error due to accidental variations is 0.34%. The method is a modification of the usual heterodyne beat arrangement. Capacity changes produced when the pressure in the test condenser is changed are compensated by a suitable condenser in parallel. The beat note frequency is compared with that of a fork by means of Lissajou's figures. The test condenser is made of invar to avoid temp. effects. Short connecting wires are used to minimize lead-inductance effects. A few preliminary measurements made with a large d. c. voltage across the condenser indicate no change in the dielec. const. of air H₂ or NH₃. There is some indication that a discharge through the gas decreases its dielec. const. but the effect is probably spurious.

BERNARD LEWIS

Association in liquid dielectrics. J. ROLINSKI. *Techn. Hochschule Warsau Physik. Z.* 29, 658-67(1928).—The elec. polarization of binary mixts. of dipole-free liquids (C₂H₆, CS₂ and CCl₄) is detd.; the independence of the mol. polarization on the concn. and the validity of the additivity law for the vol. polarization is established. A binary mixt. of a dipole substance (ethyl ether, chlorobenzene and quinoline) with a dipole-free substance (benzene) is studied and it is shown that the mol. polarization

of these dipole substances are not const. but decrease with rising concn; this indicates assocn. of the mols. On the basis of the fact that in the substances being studied, the dipole moment of 2 assocd. mols. vanishes, the assocn. degree, i. e., the proportion of the assocd. mols. to the total go. is calcd. and it is found that it increases with increasing concn. and at equal concns. it is larger, the stronger the dipole moment of the assocd. liquid. The additivity law in the binary mixts. of the above dipole liquids is not fulfilled for vol. polarization and the deviation is explained by assocn. M. F.

Further Röntgen spectroscopy measurements in the L- and M-Series of rhenium. H. BRÜHSE. *Z. Physik* 50, 762-8(1928); cf. *C. A.* 22, 1276.—The weaker lines of the L-series of Re, the L-absorption bands and the strongest lines of the M-series are measured and the corresponding term values are calcd. The detn. of the wave lengths of weaker lines forms an extension of the earlier work on the L-series of Re (cf. *C. A.* 22, 1276). The wave lengths of 25 L-series lines ranging from 991.0 to 1627.3 X. U. are tabulated; the L-absorption limits are measured at 1173.8, 1034.0, and 987.1 X. U., and 4 M-series lines are measured at 6708, 6692, 6491 and 5875 X. U. W. F. M.

Theory of the double x-ray spectrometer. M. M. SCHWARZSCHILD. Columbia Univ. *Phys. Rev.* 32, 162-71(1928).—The geometric factors in the construction and use of the double x-ray spectrometer are examd. in detail. The resolution of the instrument is not affected by the width of the slits but the height of the slits must be limited to preserve resolution. A formula is given for the limiting value of the ratio of the av. height of effective slits to the distance between effective slits for any particular width of observed line, in order that the width observed be the result principally of the physical factors. The phys. factors, namely, crystal imperfection, line width, diffuseness of absorption limits, are also discussed and formulas are derived by means of which the exptl. curves found with the instrument may be interpreted physically. B. L.

Further x-ray investigation of long-chain compounds (*n*-hydrocarbon). ALEX MÜLLER. *Proc. Roy. Soc. (London)* A 120, 437-59(1928).—The present investigation was made with a single crystal of the natural hydrocarbon $C_{29}H_{60}$. This material was carefully purified and its compn. checked not only by analysis but also by the comparison of its powder x-ray diagram with similar diagrams of the synthetic products $C_{30}H_{62}$ and $C_{31}H_{64}$. The natural product by this method was clearly indicated as C_{29} . The minute crystal was attached to a thin glass fiber and placed in the goniometer of an x-ray spectrograph so that complete rotation and oscillation photographs could be taken with copper radiation. The *d*, determined by the flotation method, was 0.95. The chief interest of the investigation was in the development of the appropriate geometrical structure factor for long-chain compounds of which this is a typical example. The application of this method made it possible to fix the structure quite definitely and the following numerical data were obtained: The crystal belongs to the orthorhombic space group Q_{16}^H . The unit cell has the dimensions $a = 7.45$ A. U., $b = 4.97$ A. U., $c = 77.2$ A. U. (error approx. $\frac{1}{2}\%$). There are four mols. to the unit cell. The cross-section area occupied by one mol. is 18.5×10^{-16} square cm. The distance between two consecutive scattering centers on either of the two lines of C atoms in the mol. is 2.537 A. U. (error approx. $\frac{1}{2}\%$). The distance between two consecutive diffracting centers in the chain is between 2.0 and 1.8 A. U. The distance between the two rows of C atoms in the mol. is between 1.6 and 1.2 A. U. The zigzag angle of the carbon chain is between 76° and 92° . The angle between the plane of the two rows and the symmetry plane in the crystal is between 23° and 39° . The gap between the ends of two consecutive mols. in the crystal, measured along the C axis, is 3.09 A. U. The distance of nearest approach between two diffracting centers on two neighboring mols. side by side is between 3.6 and 3.9 A. U. The distance of nearest approach between two diffracting centers on neighboring mols. end to end is about 4.0 A. U.

A. W. KENNEY

X-ray diffraction in liquids: a comparison of isomers of normal heptane and of certain carbon chains. G. W. STEWART. Univ. of Iowa. *Phys. Rev.* 32, 153-61(1928).—With the K_α doublet of Mo, diffraction ionization curves are reported on synthetic decane, 2,2,4-trimethylpentane, 2-methyl-2-hexylene and the following 8 isomers of *N* heptane: 2,2,3-trimethylbutane, 3,3-, 2,3-, 2,2- and 2,4-dimethylpentane, 3-ethylpentane, 3-methylhexane and 2-methylhexane. The expts. are a continuation of former work (cf. *C. A.* 21, 3549; 22, 1098 and Stewart and Skinner, *C. A.* 22, 1098). The diffraction peak of synthetic decane occurs at precisely the same angle as that of the other *N* paraffins contg. from 5 to 15 C atoms so that the diam. of the *N* paraffin chain throughout this range, as computed by Bragg's diffraction law, is 4.04 A. U. The experience with *N* decane was a repetition of that with *N* pentane previously reported. The length of the chain is in agreement with the formula, $L = (1.24 n +$

2.70) $\times 10^{-8}$ cm. if n is the no. of C atoms, and if the mols. may be regarded as longitudinally parallel and in square array in the plane normal to their lengths. The agreement is within less than 1%. With the exception of 2-methylhexane wherein 2 diams. are found, and of 3-ethylpentane which is a sym. branched structure, all the other heptane isomers, 6 in no., have diams. that are 1.04 A. U. larger than the N paraffins. A consideration of this fact and of the alterations in density not in agreement with the formula just cited brings the conclusion that the mol. chains of the isomers are distorted either by bending or by another type of atom sepn. A tentative conclusion is that the attachment of 2 CH_3 groups to the same atom may or may not increase the diam. by the same amt., this depending upon whether a third CH_3 branch is attached to an adjacent atom or to the next but one. The attachment of a CH_3 group on the next to end C atom seems, in the case of 2-methylhexane and 2-methyl-2-hexene, to produce 2 sym. branches of one CH_3 group each. Both this and the preceding conclusion are highly tentative but suggest the possibility of learning more of the nature of the chain by more extended expts. on isomers of N paraffins. The foregoing expts. contribute to our knowledge of mol. structure and to the evidence for the cybotactic state as one of importance in fundamental phenomena in liquids. B. L.

Methods of x-ray analysis. C. GOTTFRIED. *Glastech. Ber.* 6, 177-83(1928).—A summary of the methods used in x-ray crystal analysis with a brief description of the theory used to interpret the exptl. results. The application of x-ray analysis to glass technology is touched upon and some of the results obtained are mentioned, viz., the devitrification of window glass with the formation of tridymite and wollastonite; the devitrification of Ce glass with the formation of crystals of CeO_2 ; the presence of fine crystals of Pb when a Pb glass is strongly heated; and the presence of cryst. Cu in copper ruby. E. VALDEN

The intensities of Röntgen spectrum lines, especially of the K-series of aluminum as dependent on the voltage of the tube. EGON LORENZ. *Z. Physik* 51, 71-94(1928).—The effect of very high exciting voltages on the intensities of x-rays was measured, first qualitatively for W, and then quantitatively for Al. The stray rays emitted by a W anticathode are attributed to excitation by secondary electrons coming from the focus of the primary electron stream. The difference between the voltage corresponding to the stray rays of shortest wave length and that of the shortest ray directly excited by the primary electrons determines the x-ray levels from which the secondary electrons are ejected. When the voltage applied to the tube becomes 40 times that required to excite an electron in a particular level the liberation of secondary by primary electrons becomes nil; i. e., the intensity of the corresponding series lines becomes zero. Quant. results of the same character, derived from expts. on Al in which thick Al and very thin foil were used for anodes, show that the intensities of the K-series increase as the square of the tube voltage until a voltage twice that of the excitation potential is reached. Thence the increase is more gradual, reaching a max. at a voltage 11 times the excitation potential. At higher voltages there is a decline in intensity, until at 40 times the excitation potential (for the foil) the intensities are zero. C. C. KRISS

Intensities of K-series x-rays from thin targets. D. L. WEBSTER, H. CLARK, R. M. YEATMAN AND W. W. HANSEN. *Proc. Natl. Acad. Sci.* 14, 679-86(1928).—The intensities of the Ag K_α lines were measured as a function of the voltage, the Ag targets being films deposited on Be and so thin (280 A. U. thick and less) that there was no appreciable retardation of the cathode rays. The results, which give the relative probability of direct K-electron ionization as a function of the energy of the cathode rays, are only in qual. agreement with the theories of Davis, of Rosseland, and of Thomas. An empirical equation is given which satisfies the observed data. C. C. KRISS

The spark spectra of selenium and tellurium. LÉON AND EUGÈNE BLOCH. *Compt. rend.* 187, 562-4(1928); cf. *C. A.* 22, 543.—Lists of wave lengths, comprised between 3400 and 2200 A. U., are presented, which belong to the following spectra: Se IV, Te II, Te III, and Te IV. The behavior of the lines in highly condensed spark discharges was the method employed for assigning them to various ions of Se and Te. C. C. KRISS

The presence of predicted iron lines in the solar spectrum and the terms in the arc spectrum of iron. CHARLOTTE E. MOORE AND HENRY N. RUSSELL. *Astrophys. J.* 68, 151-64(1928).—A new table of terms is presented for the Fe arc spectrum which includes all known to date. All the possible term combinations have been calcd. with the result that wave lengths of lines which should occur but have not yet been observed in lab. sources are now available. Of these, 289 have been identified among the solar lines of hitherto unknown origin. A table lists the new lines together with their term com-

binations and solar identifications. A prolonged exposure to the Fe arc has brought out a no. of these previously unobserved lines. C. C. KIESS

The influence of various substituents on the color and absorption spectra of indigo, thioindigo and indirubin. J. FORMANEK. *Z. angew. Chem.* 41, 1133-41(1928).—See C. A. 22, 3583. E. H.

The K-Röntgen absorption spectrum of potassium in various compounds. ORRO STELLING. *Z. Physik* 50, 626-9(1928).—Since it is of theoretical interest to know the the K-absorption spectrum of a positive ion in different compds., the K-limit of the free element K and of 27 salts of K is accurately measured. The wave length for the element is 3431.0 X. U., but for compds. contg. K it is 3.1 to 5.5 X. U. smaller. W. F. MEGGERS

Measurements of the M-series in the Röntgen spectra of the elements from uranium to gadolinium. ERNST LINDBERG. *Z. Physik* 50, 82-96(1928).—A careful survey has been made of the M-series of the elements from U(92) to Gd(66) including Re(75) and Hf(72). A Siegbahn precision vacuum spectrometer was used in the work, and the results cover the wave-length interval from 2.5 to 11.5 A. U. The wave-length measurements for each element are listed in comprehensive tables, as are also the values of V/R and $\sqrt{V/R}$ derived from them. C. C. KIESS

Investigation of the band spectrum of mercury hydride. E. HULTHÉN. *Z. Physik* 50, 347-62(1928).—New bands have been observed in the spectrum of HgH , in particular one at 4902 A. U., which corresponds to the long wave convergence point conditioned by the dissociation of the mol. This band and also the ones at 3500 A. U., and 3274 A. U. of the system $^2P - ^2S$ have been analyzed on the basis of the new wave-length measurements. New bands, degraded toward the red, in the region 3100 to 2900 A. U., have been analyzed and assigned to the system $^2S - ^2S$. The term analysis of these systems is in all points in harmony with Hund's theory (C. A. 21, 1226, 1930, 3310) including the fine structure relationship. C. C. KIESS

Interpretation of band spectra. II. R. DE L. KRONIG. *Z. Physik* 50, 347-62(1928).—A theoretical investigation of the diatomic mol. on the basis of the wave mechanics (cf. C. A. 22, 1278). C. C. KIESS

The band spectrum of beryllium oxide. ERNST BENGTSSON. *Arkiv Mat. Astron. Fysik* 20A, no. 28, 1-18 pp.(1928).—Analysis of the 2 groups of bands of BeO at 4709 A. U. and 4427 A. U. shows that the lines belong to either simple P or R branches. The formula derived for the null lines is $\nu_0 = 21196.9 + 1363.0 n' - 8.0 n'^2 - 1417 n'' + 10.15 n''^2$, in which n' and n'' are resp. the quantum nos. of the nuclear vibrations in the initial and final states. From the rotational terms determined empirically are derived values for the initial and final moments of inertia of the mol. and also for the separ. of the at. nuclei. For the dissoci. energy a value of 6.1 v. or 140 cal. was found. In the ultra-violet a group of bands was measured of which the wave nos. are given by $\nu = 31890 + 1006 n' - 10 n'^2 - 1126 n'' + 10 n''^2$. C. C. KIESS

The oscillation and rotation spectrum of a molecule of the type of methane. W. ELERT. *Z. Physik* 51, 6-33(1928).—Hund has given the theoretical term scheme for mols. with more than 2 nuclei (C. A. 21, 3310). His method is here extended to mols. of the type of CH_4 but limited to the vibration-rotation spectrum. On the assumption that the equil. position of the nuclei is a regular tetrahedron with the 4 similar nuclei at the vertices and the fifth occupying the center, the symmetry relations of the vibration and rotation characteristic functions are derived, and the term scheme is worked out. The results thus obtained are used in calcg. the sp. heats of methane. C. C. K.

Interpretation of the atmospheric oxygen bands; electronic levels of the oxygen molecule. R. S. MULLIKEN. *Nature* 122, 505(1928). The electron configuration which gives rise to the normal state, 3S , of the mol. O_2 also gives rise to the metastable states 1D and 1S , the latter lying 1.62 v. above the normal 3S . The atm. bands of O_2 which appear in the red end of the solar spectrum are attributed to the transition $^3S \rightarrow ^1S$, the initial 3S being the state which combines with the normal 3S to give the Schumann-Runge bands in the ultra-violet. C. C. KIESS

The wide bands of continuous absorption in the halogens. P. BOVIS. *Ann. phys.* 10, 232-344(1928).—By the standard methods of spectrophotometry the absorption spectra of extremely thin lamina of Br and I are studied in the visible and ultra-violet. The absorption spectra of certain salt solns. serving as photometric standards are first investigated. These include 0.1 N solns. of CuSO_4 , CuCl_2 , $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2$, CoSO_4 , CoCl_2 , mixt. of CuSO_4 and CoCl_2 , NiSO_4 , NiCl_2 and K_2CrO_4 . The stability of these solns. has been tested during 4 years and their absorption spectra are found to be practically invariable. The violet and ultra-violet absorption of liquid Br is investigated between 5° and the b. p. of Br at normal pressure. By comparing the results with

liquid Br and with gaseous Br it is seen that in the 2 different states Br possesses a violet band in common; the max. absorption occurs for $\lambda 0.421 \mu$. But the max. optical density referred to the same mass of Br traversed by the light is 2 times greater for the liquid than for the gas. While the abrupt side of the absorption band is toward longer wave lengths according to theory the absorption bands of the halogens actually face in the opposite direction. The effect of temp. on the opacity of liquid Br is the same as if its coeff. of expansion were 70 times greater than it really is. The absorption of dil. solns. of Br in water, CHCl_3 , CCl_4 , CS_2 and EtOH is also observed. Besides the violet band of Br which is more or less displaced and widened a strong narrow band is measured in the ultra-violet near 0.260μ . The absorption spectrum of solid I in layers about 0.5μ thick was measured; a wide band with max. intensity at 0.255μ appears to correspond to the region of continuous absorption reported for I vapor in the region 0.206μ . The absorbing properties of solid I are complicated by phenomena of pleochroism, of which a brief study was also made.

W. F. MEGGERS

Spectra of mercury at atmospheric pressure. W. H. CREW AND L. H. DAWSON. *J. Optical Soc. Am.* 17, 261-70 (1928).—Light from a Hg arc in quartz, operating at atm. pressure, and excited by various elec. means was photographed through a quartz spectrograph. With very high currents through the arc some 13 lines were found to be self-reversed, 2 of which are spark lines. The reversal of one of these ($\lambda 1942$) supports the view of Carroll, Turner and Compton that it is a member of the first doublet of the principal series of Hg^+ . Lines of the diffuse series of Hg appear to be the most readily reversed. With relatively low currents through the arc the continuous spectrum appears in 4 discrete bands, 3 of which have intensity maxima lying close to the 3 spectral series limits: $\lambda 4580$; $\lambda 3320$; $\lambda 2240$. A modification of Bohr's theory, which attributes bands of continuous radiation to the recombination of electrons with at. or mol. ions, agrees very well with the observed facts.

W. F. MEGGERS

Wave lengths and Zeeman effects in the yttrium spectra. WM. F. MEGGERS. *Bur. Standards J. Research* 1, 319-41 (1928).—The wave lengths corresponding to approx. 1000 lines photographed in the arc and spark spectra of Yt were measured relative to secondary standards in the Fe spectrum. The values extend from 2127.99 Å. U. in the ultra-violet to 9494.81 Å. U. in the infra-red. Comparison of relative intensities and other characteristics of lines in the different sources permitted a sharp discrimination between 4 classes of lines; about 500 are ascribed to neutral atoms (constituting the Yt I spectrum), 240 originate with singly ionized atoms (Yt II spectrum), 10 belong to doubly ionized atoms (Yt III spectrum), and most of the remainder describe the band spectrum characteristic of mol. compds., presumably Yt oxide. Measurements of Zeeman effects for 220 Yt lines ranging in wave length from 3173 Å. U. to 6896 Å. U. are included.

W. F. MEGGERS

Supplements to the spectra of neon, argon and krypton. W. GREMMER. *Z. Physik* 50, 716-24 (1928).—A 4-m. concave grating was used to photograph the spectra of Geissler tubes contg. Ne, Ar, or Kr. Exposures of 36 to 60 hrs. revealed some new red and infra-red lines which with Ne and Ar are in large part explained as members of known *sp*-, *ps*- or *pd*-series. The Kr spectrum shows similarity in structure with the Ne and Ar spectra; 4 *s*-terms are established from their sepns. which appear as const. differences between the wave nos. of Kr lines; the sepns. are 655.0, 4275.1 and 944.9 cm^{-1} .

W. F. MEGGERS

Isotopes of neon. T. R. HOGNESS AND H. M. KVALNESS. Univ. California. *Nature* 122, 441 (1928).—The isotope Ne^{21} has always been observed while Ne is used as a calibrating gas. The possibility of a hydride of Ne^{20} is eliminated since no ion of mass 23 was found, which would correspond with the hydride of Ne^{22} . Atm. Ne is composed of 10% of Ne^{21} , 2% of Ne^{22} and the remainder Ne^{20} . JAMES M. BELL

Anomalous dispersion of unexcited gases. III. Transformation and density of unexcited atoms in neon: statistical equilibrium in the positive beam. HANS KOPFERMANN AND RUDOLF LADENBURG. *Z. Physik* 48, 51-61 (1928); cf. *C. A.* 22, 4364.—From the values for anomalous dispersion of the yellow-red Ne lines the relative oscillator strength f_{ij} , and the transformation probability A_{ij} , have been calc. for the corresponding lower state j . The values thus obtained are independent of current and pressure. The relative at. densities have been calc. for the S_2 , S_1 and S_0 states. The ratios $N_2:N_1:N_0$ approximate to 100:60:20 of the statistical equil. at very high temps., when the current increases (independently of pressure). From these values, the A value of all the lines has been calc. By using the f summation law the same result is obtained. Finally, the abs. values of the oscillator strengths, the transformation probabilities, the life period and the atom densities in the unexcited S state have been estd.

S. L. B. ETHERTON

Investigations on anomalous dispersion in calcium, strontium and barium vapor. V. PROKOPIEV. *Z. Physik* 50, 701-15(1928).—By the app. and method (Hook method of Roschdestwensky) described elsewhere (*Z. Physik* 48, 276 (1928)), the anomalous dispersion in Ca, Sr and Ba vapor is investigated in the vicinity of the resonance lines $1^1S_0 - 2^1P_1$ and $1^1S_0 - 2^3P_1$. The ratio of the no. of dispersing centers for the first and second line decreases rapidly with increasing at. no.; for Ca it is 33,000, for Sr 1660, and for Ba, 146. The relative probability A_2 of the spontaneous transition of the intercombination line $1^1S_0 - 2^3P_1$, assuming the probability of spontaneous transition of $1^1S_0 - 2^1P_1$ as unity, satisfies the interpolation formula $A_2 = \frac{1}{2}(\Delta\nu/\delta\nu)^{1.44}$ in which $\Delta\nu$ and $\delta\nu$ signify the term differences $2^3P_1 - 2^3P_0$ and $1^1S_0 -$ center of gravity of $2^3P_{0,1,2}$ in cm^{-1} . The relative probabilities for Mg and Zn are calcd. from this relation. W. F. MEGGERS

Note on the extinction of the D-lines in flames by addition of chlorine. J. FRANCK AND G. E. GIBSON. *Z. Physik* 50, 691(1928).—The extinction of the D-lines of Na in a flame when Cl is added may be explained either by the transformation of free Na atoms into NaCl, or by the return of excited Na atoms to the normal state through collisions of the second kind with Cl. Comparison of the disappearance of the D-lines in absorption with their extinction in emission indicates that the extinction of the D-lines is due to the disappearance of free Na atoms. W. F. MEGGERS

The carrier of the Fulcher spectrum of hydrogen. E. HIEDEMANN. *Z. Physik* 50, 618-25(1928).—It is well known that the portion of the "many-lined" spectrum lying between H_α and H_β , the so-called Fulcher bands, react differently to variations in excitation conditions than the remainder of spectrum. A detailed discussion of all the observational material leads to the conclusion that the Fulcher bands are emitted from a lower excitation level of the H_2 mol. than the remaining lines; and that they do not belong to the H_2 mol. as others have stated. W. F. MEGGERS

Favoring the appearance of the Balmer lines by the addition of argon. E. HIEDEMANN. *Z. Physik* 50, 609-17(1928).—Observing the discharge in a tube contg. pure H at 0.5 mm. Hg pressure and operated by high-frequency oscillations showed the first 3 Balmer lines and the "many-lined" spectrum with about equal intensity, the Fulcher bands appearing especially strong. Addn. of A to the H did not weaken the Balmer spectrum appreciably but the many-lined spectrum was completely extinguished, the Fulcher bands being the last to disappear. The action of A on the excitation processes is thought to be the following: with increasing addn. of A lower excitation stages are preferred and the short-wave portion of the many-lined spectrum therefore vanishes before the Fulcher bands. The relatively strong Balmer spectrum is due to the relatively long life and strong excitation of the H atoms formed, and the frequency of their formation is increased by collisions of the second kind which simultaneously depress the many-lined spectrum. W. F. MEGGERS

The absorption spectrum of cesium. IRENE MAUD MATHEWS. *Proc. Roy. Soc. (London)* A 120, 650-4(1928).—The light from a C arc after passing through a steel tube 3 ft. 6 in. long contg. Cs vapor was photographed with a concave grating of 10 feet radius; 32 members of the principal series of Cs were recorded as absorption lines. The doublets could not be resolved beyond the 8th. An effort was made to measure the wave lengths to an accuracy of about 0.02 Å. U., thus improving on the earlier measurements by Bevan (*C. A.* 7, 300) whose estd. error for most lines was 0.2 Å. W. F. M.

The first spark spectrum of krypton. P. K. KICHLU. *Proc. Roy. Soc. (London)* A 120, 643-9(1928).—Analysis of the published data on the spark spectra of Kr has revealed 42 levels in the spectrum of Kr^+ . Combinations of these levels account for about 160 spectral lines. The normal state of the Kr^+ atom is represented by a 3P term with sepn. of 5371 cm^{-1} . A Rydberg sequence of 3P terms gives the limit as 214,000, which corresponds to an ionization potential of 26.4 v. This is somewhat lower than the value 28.25 measured by Dejardin, but the discrepancy is perhaps due to the fact that the spectroscopic value is based upon an extrapolation from only the first 2 nos. of a series (cf. *C. A.* 22, 27 3837). W. F. MEGGERS

The quantum mechanics of the rotational distortion of multiplets in molecular spectra. E. HILL AND J. H. VAN VLECK. *Univ. of Min. Phys. Rev.* 32, 250-72 (1928).—The purpose of this paper is to give frequency and intensity formulas, for diatomic mols., applicable to the transition stage intermediate between the limiting cases (a) and (b) of Hund (*C. A.* 20, 2283; 21, 1228, 1930), namely, for very tight coupling and for very weak coupling, resp., of the spin axis. The treatment is by the new quantum mechanics, which has the advantage of yielding a simple frequency formula for the doublet case as well as exact expressions for the intensities. The last section is devoted to a consideration of " σ -type doubling." Interaction of σ -type

degeneracy is not treated here so that this section deals primarily with singlet states.

BERNARD LEWIS

An approximation method and application to some HCl bands. D. G. BOURGIN. Dept. of Math., Univ. of Illinois. *Phys. Rev.* 32, 237-49(1928).—A method of approximation applicable to some exptl. investigations is based on the inversion for $\mu(\nu)$ of the integral equation, $A(x) = \int_0^\infty (1 - e^{-\mu(\nu)x}) d\nu$. The general nature of the interdependence of $A(x)$ and $\mu(\nu)$ is described and a practicable method of characterizing certain types of $\mu(\nu)$ is developed in sufficient detail to permit of immediate application of the results. B.'s previously published data (*C. A.* 21, 2224; *Phys. Rev.* 31, 704 (1928)), for the HCl fundamental band lines has been approximated by line patterns based on the hypothesis of (a) Doppler broadening or error curve structure, (b) a Stark broadening due to the mol. force field set up by neighboring mols. and (c) an interrupted absorption process or dispersion curve type. The modifications attendant on recognizing the isotopic doubling of the lines are predictable from the calcn. for a doublet structure of infinite component sepn. The values of the line intensities and breadths and the Einstein coeffs. A_{10} and B_{10} are given for each of the assumed structures. Kinetic-theory considerations make it improbable that the Doppler effect is the primary detg. influence as regards line shape. The Lorentz line with a possible Doppler broadening superposed would seem to reproduce the exptl. data satisfactorily. The results are in keeping with an at. binding for HCl and if the at. character of the dissocn. products be accepted, it appears that the dielec.-const. measurements lead directly to the order of magnitude of the values for $\int_0^\infty \mu(\nu) d\nu$. This lends further support to Van Vleck's (*C. A.* 21, 2840) criticism of that explanation of the discrepancy between the extrapolated optical and direct measurements of the dielec. const. of HCl which depends on an appeal to the infra-red vibration bands. Some aspects of the recent work on the coupling effect in gases are examd. and Badger's (*C. A.* 21, 2844), data in the pure rotational spectrum of HCl have been studies on the assumption of a line structure derived on the basis of such "coupling" pressure broadening. The value for the line intensity found here is in slightly better agreement with the new quantum theory but the discrepancy is still excessive.

BERNARD LEWIS

The rotational structure of the blue-green bands of Na. F. W. LOOMIS AND R. W. WOOD. Alfred Loomis Lab., Tuxedo Park, N. Y. *Phys. Rev.* 32, 223-36 (1928).—Because of the theoretically impossible structure of these bands, as reported by previous observers, the authors have measured them, in absorption, in the 3rd-order spectrum of a 7-in. plane grating mounted in a 40-ft. spectrograph. Each band consists of only one P, one Q and one R branch. This accords with Mulliken's (*C. A.* 21, 206, 1057) theory that the electronic transition is $^1P - ^1S$, and with the nature of the fluorescence series. Moreover, the absorption series correlate properly with the fluorescence series. The combination relations have been applied to all measured bands and found to hold, rigorously with the exptl. error, except for the expected PQR defect, which is very small. The more important consts. of this band system are: $B_0'' = 0.15431$, $I'' = 179.5 \times 10^{-40}$ g. sq. cm., $r_0'' = 3.08 \times 10^{-8}$ cm., $\alpha'' = 0.00082$, $B_0' = 0.12541$, $I_0' = 220.9 \times 10^{-40}$ g. sq. cm., $r_0' = 3.41 \times 10^8$ cm., $\alpha' = 0.00094$. These extremely large internuclear distances correspond to weak mol. binding, which is in accord with the low heat of dissocn. reported by Loomis (*C. A.* 21, 1227-8). The locus of most intense vibrational transitions calcd. from these consts. and the previously reported vibrational consts., by the method of Franck and Condon, is a good representation of the observed distribution. There is no evidence of alternating intensities. B. L.

Extreme ultra-violet spectrum of argon excited by controlled electron impacts. K. T. COMPTON, J. C. BOYCE AND H. N. RUSSELL. Princeton Univ. *Phys. Rev.* 32, 179-85(1928).—Circulating purified A was excited by electrons from a Wehnelt cathode at various voltages up to 150 v., with gas pressures of about 0.05 mm. and currents of about 100 milli-amp. Such excitation has been shown to arise from single rather than multiple electron impacts. The spectrum was photographed with the aid of a high-vacuum spectrograph equipped with a glass grating. Eighty-eight lines, all believed to be due to A, have been found in the wave-length region 1066 to 461. Twenty of these belong to the known arc spectrum. Of the remaining 68 spark lines, 44 have not previously been reported. Previously known A III lines were not excited, so that the authors attribute the 68 spark lines to A II. Thirty-seven spark lines have been classified. Twelve of these classifications have been checked by numerous combinations involving lines in the near visible region (6883-2300). Tables of lines, terms and combinations are given. Three series of 2 members each give the series limit as 223, 363, so that the ionization potential is 27.82 ± 0.05 v. Adding the first ionization potential

15.69 v. gives 43.51 v. as the min. potential for double ionization. These refer to ionization to the 3P_2 limit, the lowest energy state of A III. A tentative term value of -33230 (relative to 3P_2) is given to the higher 1D limit. BERNARD LEWIS

The spectrum of sulfur, S II. S. B. INGRAM. Cal. Inst. of Tech. *Phys. Rev.* 32, 172-8(1928).—One hundred and eighty-three lines are classified in the spectrum of S II. 33 terms of the quartet system, 36 of the doublet system are detd. and correlated with the electron configurations by means of the Hund theory. The ionization potential of the S II ion is fixed at 23.3 ± 0.1 v. BERNARD LEWIS

The near infra-red absorption of artificial and natural sylvin. CLEMENS SCHAEFER AND CARL BORMUTH. *Z. Physik* 50, 363-5(1928).—The absorption bands at 3.23μ and 7.23μ observed by Coblenz, by Reinkober, and by the authors, in natural crystals of sylvin, are not exhibited by artificial crystals. This leads to the idea that these bands are due to an impurity in the natural crystal. It is pointed out that this impurity may be NH_4Cl , since the NH_4 group has 2 bands at exactly 3.22μ and 7.08μ . C. C. KIESS

Recombination light of the halogens. V. KONDRAT'EV AND A. LEIPUNSKII. *Z. Physik* 50, 366-71(1928).—A tube containing I vapor heated to 1000° glows with yellowish light, which consists of bands in the red, yellow and green. These bands correspond with those observed in absorption, and extend into the region covered by the absorption bands to wave lengths shorter than the convergence point; thus indicating that in the formation of the mol. I_2 , a normal and an excited atom combine with emission of energy equal to $h\nu$. Similar results were obtained with Br and Cl. C. C. KIESS

Remark on the broadening of spectrum lines by the vapor density of the absorbing atoms. ECKHART VOGT. *Z. Physik* 50, 395-6(1928).—It is pointed out that Trumpy's results for widening of lines, due to coupling as distinguished from widening due to impact by a foreign gas, range from 300 to 600 times larger than those obtained by Schütz. C. C. KIESS

The magneto-optical determination of the intensities of the first two members of the principal series of potassium and the vapor pressure of potassium. J. WEILER. *Z. Physik* 50, 436-9(1928).—From measurements of the magnetic rotation in the vicinity of absorption lines the intensities of the lines may be derived. For the first pair of the principal series of K an intensity ratio of 1.96 was thus detd.; and 1.94 for the second pair. The intensity of the first pair was detd. as 96 times that of the second. The measurements furnish as an empirical formula for the vapor pressure $\log pT = (20000/4.571T) + 9.866$. C. C. KIESS

The infra-red absorption spectra of organic sulfur compounds. II. Aryl groups containing mercaptans and sulfides. FREDERICK K. BELL. *Ber.* 61B, 1918-23(1928).—The absorption spectra of benzyl mercaptan, thiophenol, thio-*p*-cresol, dibenzyl sulfide and diphenyl sulfide were measured between 1.0μ and 12.0μ . The mercaptans are characterized by a pronounced band at 3.9μ , which is not present in the sulfides, and which serves as a test for distinguishing the 2 classes of compds. The 3.9μ band is most intense for pure aryl mercaptan and least so for pure alkyl mercaptan, its intensity for aryl-alkyl and alkyl-aryl mercaptans lying between these limits and approx. of the same magnitude. Curves illustrating the absorption of the compds. are given. C. C. KIESS

Series spectra of cadmium-like atoms. J. B. GREEN AND R. J. LANG. *Proc. Nat. Acad. Sci.* 14, 706-10(1928).—A classification of the spectrum Sb IV is given. The lowest term is $5^1S = 340,000 \text{ cm.}^{-1}$, from which an ionization potential of 42 v. is calcd. An extended classification of In III is also presented. C. C. KIESS

The band systems in the spectrum of I_2 vapor. PETER PRINGSHEIM AND B. ROSEN. *Z. Physik* 50, 1-14(1928).—A new system of ultra-violet absorption bands of I_2 vapor, which appear only when the gas is heated to 500° or more, is described. The wave nos. of these bands satisfy the formula $\nu = 41,900 + 70 n' - 90 n$, in which the no. n' refers to the position of a band within a group, and n to the position of the group within the system. In the near infra-red addnl. bands extending the systems already known have been observed. A term scheme is set up in which the new bands are linked with all the previously known band systems of I_2 . C. C. KIESS

A note on the series spectra of Sn IV and In III. K. R. RAO, A. L. NARAYAN AND A. S. RAO. *Indian J. Physics* 2, 477-83(1928).—With the aid of Lang's results (C. A. 21, 2433) it has been possible to extend the classification of Sn IV indicated by Rao (C. A. 21, 3828) and to place the lowest term 1^2S at $328,671 \text{ cm.}^{-1}$, giving 40.57 v. as the fourth ionization potential of Sn. For In III a new list of terms is given upon which the

classification is based. The lowest term $1^2S = 226,133$ gives an ionization potential of 27.91 v. C. C. KIESS

The spectrum of the hydrogen molecular ion. C. J. BRASEFIELD. *Proc. Nat. Acad. Sci.* 14, 686-89(1928).—It has previously been shown that at very low pressures the particles in the luminous canal-ray beam in H are practically entirely H_2^+ ions. The spectrum of this beam should therefore consist solely of bands emitted by H_2^+ . The wave lengths measured from plates obtained at pressures of 0.001, 0.002, 0.003, 0.004, 0.005, 0.006, 0.008 and 0.014 mm. are presented, and it is shown that some of them can be arranged into 3 Q branches degrading toward the red. The heads of the 3 bands are represented by the simple Rydberg formula $\nu = 27,743 - 4R/(m + \mu)^2$, where $m = 8, 9, 10$ and μ is approx. zero. C. C. KIESS

The absorption spectrum of nitrogen dioxide. LOUIS HARRIS. *Proc. Nat. Acad. Sci.* 14, 690-4(1928).—Expts. are described for obtaining the absorption spectra of NO_2 and $(NO_2)_2$. The single mols. absorb a large no. of bands, many with fine structure, from 6000 A. U. to 2250 A. U. The absorption of the double mols. in the gaseous state is continuous. The band of NO_2 at 2490 A. U. seems to be best for analysis of its structure, its lines being represented by the relation $Q_m = 40129.7 + 3.7 m^2$, where m varies from 0 to 12. C. C. KIESS

A new class of spectra due to secondary radiation. I. C. V. RAMAN AND K. S. KRISHNAN. *Indian J. Physics* 2, 399-419(1928).—When light from a quartz Hg lamp is scattered within a liquid a large no. of new lines, not in the incident light, are observed in the spectrum of the scattered light. Each liquid investigated (benzene, toluene, pentane, ether, MeOH, H_2O) shows a characteristic scattered spectrum, but for liquids having similar chem. groups in their compn. certain general similarities appear in the spectra. Measurements of the scattered spectrum of benzene show that for each line in the incident spectrum 7 scattered lines appear, of which 6 have wave nos. lower than that of the exciting ray and one has a higher wave no. The wave-no. differences between the exciting and scattered lines agree with certain characteristic infra-red frequencies of the mol. of the scattering liquid (C. A. 22, 4060). The phenomena are accounted for on the assumption that part of the incident energy is absorbed and part scattered by the mol. If the mol. is raised from its normal to a higher state the scattered radiation will be of lowered frequency, but if it is brought from a high energy state to a lower, the scattered radiation will be of higher frequency than the incident radiation. C. C. KIESS

The series spectra of mercury-like atoms (Tl II and Pb III). K. R. RAO, A. L. NARAYAN AND A. S. RAO. *Indian J. Physics* 2, 467-76(1928).—In the spectra of Tl II and Pb III multiplets have been found which represent the combinations $1^3D - 1^3F$, $1^3P - 1^3D$ and $1^3P - 1^3S$, and in addn. in Pb III, $2^3P - 1^3S$, $2^3P - 2^3S$ and $2^3P - 1^3D$. By assuming values for 3F the values of 1^3S , the lowest term of each spectrum, have been calcd., from which ionization potentials of 20.3 v. and 31.5 v. have been found for Tl^+ and Pb^{++} , resp. C. C. KIESS

Wave-length measurements in the arc and spark spectra of hafnium. WM. F. MEGGERS. *Bur. Standards J. Research* 1, 151-87(1928).—With the purest available samples of Hf salts the arc and spark spectra characteristic of this element were photographed with concave-grating and quartz-prism spectrographs. Wave-length measurements were made on about 2100 lines, but 600 of these were discarded as impurities, identified mainly as Cb, Zr and Ti. Nearly 1500 lines remain to describe the Hf spectra between the wave-length limits 2155.72 A. U. in the ultra-violet and 9250.27 in the infra-red. In this investigation an attempt has been made to improve upon an earlier description of these spectra, (1) by extending observations to shorter and to longer waves, (2) by increasing the precision of the wave-length measurements to ± 0.01 A. U. and (3) by making a more crit. differentiation between lines characterizing neutral atoms (Hf I) and those ascribable to ionized atoms (Hf II). Comparison of these results with the earlier measurements of Zr spectra proves that Hf was invariably present as an unrecognized impurity. The most sensitive Hf I and Hf II lines for spectrochemical identification are tentatively selected; the *rate ultime* for neutral Hf atoms is probably 4093.17 A. U. and for ionized atoms the line at 2773.37 A. U. The stronger Hf II lines are identified with faint Fraunhofer lines in the sun's spectrum. W. F. MEGGERS

The spectrum of doubly ionized magnesium. J. E. MACK AND R. A. SAWYER. *Science* 68, 306(1928).—An investigation of the condensed spark discharge in vacuum between electrodes of pure metallic Mg has revealed the levels of the most stable 3 configurations of the doubly ionized atom, isoelectronic with Ne. Relative values of the spectral terms of Mg^{++} arising from electron configurations $2p^4$, $2p^33s$ and $2p^23s^2$

are published and an ionization potential of 80 ± 2 v. is deduced for the Mg^{++} atom.

W. F. MEGGERS

The Zeeman effect for the spectrum of tantalum. J. C. McLENNAN AND A. M. I. A. W. DURNFORD. *Proc. Roy. Soc. (London)* A 120, 502-10(1928).—The Zeeman effects for 55 lines in the arc spectrum of Ta between 5584 Å. U. and 6676 Å. U. are photographed with a concave grating of 3 m. radius, the source being an arc in a magnetic field of about 21,500 gauss. Almost all of the patterns are measured as triplets but there is evidence that many of the lines are more complex.

W. F. MEGGERS

Tables of theoretical Zeeman effects. C. C. KIESS AND W. F. MEGGERS. *Bur. Standards J. Research* 1, 641-84(1928).—Landé has shown (C. A. 17, 2992) that the anomalous Zeeman effects can be expressed in terms of the normal triplet by multiplying it by a coeff. gm , in which m is the magnetic quantum no. and g is the splitting factor, a function of the quantum nos. R , K and J . In the present paper extensive tables give the theoretical Zeeman patterns based on Landé's g 's, for all term combinations of the doublet, quartet, sextet and octet even multiplicity systems; for the triplet, quintet and septet odd systems; and for the corresponding inter-systems.

C. C. KIESS

Series in the arc spectrum of chlorine. T. L. DE BRUIN AND C. C. KIESS. *Science* 68, 356-7(1928).—At the Bureau of Standards the arc spectrum of Cl has been photographed out to 9900 Å. U. in the infra-red. The new lines have been classified as members of the doublet and quartet systems. The lowest term is 2P coming from the electron configuration s^2p^4 . The other terms which have been established are 3P and 4P coming from s^2p^4 , and two sets of doublet and quartet S , P and D terms arising, respectively, from s^2p^4 and s^2p^4 .

C. C. KIESS

Supplementary note to "an interpretation of the continuous spectrum of hydrogen." YUTAKA TAKAHASHI. *Sci. Reports Tôhoku Imp. Univ. (Japan)* 17, 963-6(1928); cf. C. A. 22, 3834. (In English).—A theory is proposed to account for the continuous H spectrum which is analogous to the theory of the continuous x-ray spectrum. It is supposed that a moving free electron collides with a H mol. of which the disson. potential is 4.38 v. and the resonance potential about 11 v. corresponding to the wavelength limits 2820 Å. U. and 1100 Å. U., resp. Even though the probability of the emission of radiation by the collision is small, there should be a fairly strong continuous spectrum if the gas pressure in the discharge tube is sufficiently high. Since not all the energy of the colliding electron is imparted to the mol. and radiated as continuous spectrum the result will be to displace the spectrum to wave lengths longer than 2820 Å. U. These assumptions will account for the spectrum previously described (C. A. 22, 3834).

C. C. KIESS

The spark spectrum of argon. II. T. L. DE BRUIN. *Z. Physik* 51, 108-13(1928).—The analysis of A II previously reported (C. A. 22, 2326) is here extended by the discovery of more doublet and quartet terms made possible by new wave-length measurements. In all, 46 terms have been identified of the 59 theoretically possible. The terms and the classified lines, 180 in all, are presented in tables. The lowest term is $^2P_2 = 224,758 \text{ cm.}^{-1}$ from which an ionization potential of 27.75 v. is derived for A'.

C. C. KIESS

The Zeeman effect of the argon spark spectrum (A II). C. J. BAKKER, T. L. DE BRUIN AND P. ZEEMAN. *Z. Physik* 51, 114-35(1928).—Of the A spark lines classified by de Bruin (cf. preceding abst.) 110 have been examd. in the magnetic field. The data for these are tabulated. Although many of the patterns are in agreement with those given by Landé's theory (C. A. 17, 2992) others, for lines originating in the higher terms, exhibit deviations from it. The terms resulting from the $4s$ electron all have the theoretical g 's; of those coming from $4p$, 7 of the 8 quartet terms have normal g 's but the 5 doublet terms all have abnormal g 's. All the terms from the $5s$ electron have abnormal g 's, which is a contradiction of Preston's rule that the same Zeeman effects are exhibited by series lines resulting from term combinations of the same type.

C. C. KIESS

Further studies on light absorption in the ultra-violet by α -amino acids, polypeptides, 2,5-diketopiperazines and betaines. EMIL ANDERHILDEN AND ERNST ROSSNER. *Univ. Halle. Z. physiol. Chem.* 178, 156-63(1928); cf. C. A. 22, 3172.—Absorption curves are given for glycylglycine, *dl*-leucylglycine, glycyl-*dl*-leucine, and the 2 corresponding anhydrides, all of which lie very close together. A redetn. of the curve for the tripeptide *dl*-leucylglycylglycine gave a somewhat different result from that previously reported because of greater purity of the material. Curves are plotted also for betaine and hordenine and their HCl salts. In order to det. whether highly purified cysteine reverts spontaneously to cystine, the curve was plotted for a freshly prepd. soln. and again after the same soln. had been allowed to stand 2, 5 and 12 days, observing

elaborate precautions such as the use of quartz vessels to avoid any possible contamination. The position of the curve gradually shifted until it occupied a position intermediate between that of cystine and that of freshly dissolved cysteine.

The absorption of the mercury line 1941.5 A. U. in the positive column and the optical determination of the concentration of mercury ions. W. DE GROOT. *Z. Physik* 50, 559-69(1928).—An expt. is described which demonstrates that the Hg line 1941.5 A. U. ($1^1S - 2^3P_{1/2}$ of ^{199}Hg) is absorbed in the pos. column of a tube contg. a mixt. of Hg vapor at 2 to 4 mm. pressure with A at 0.25 mm. pressure. The source was a low-voltage arc contg. Hg in an atmp. of Ne at 17 mm. The observations consisted in measuring the absorption of 1941.5 as a function of the current used to excite the vapor in the absorption tube. From these observations the no. of Hg ions per cc. ranged from 1.6 to 3.2×10^{10} for a tube with a pos. column 80 cm. long and 2.6 cm. diam., carrying current of 100 milliamp. at 150 v. C. C. KIESS

The intensities of forbidden lines in the magnetic field. W. C. VAN GEEL. *Z. Physik* 51, 51-61(1928).—In the Zn I spectrum the forbidden lines P_0D_1 , P_1D_1 and P_0D_2 of the multiplet at 3345-3282 A. U., were excited in a magnetic field and their intensities were measured in relation to the non-forbidden lines. For P_0D_2 and P_1D_1 it was possible to measure also the intensities of their Zeeman components. The observed intensities although showing a satisfactory agreement with the theoretical values are in general somewhat larger than the calcd. values. But for the positions of the Zeeman components the observed values differ from the theoretical by amounts greater than the permissible errors of measurements. This is attributed to a perturbation of the term 3D by the term 1D , which lies very near it. C. C. KIESS

Calculation of intensities for incipient Paschen-Back effect. A. ZWANN. *Z. Physik* 51, 62-70(1928).—The matrix theory of the Zeeman effect given by Heisenberg and Jordan (*C. A.* 21, 1753) has been developed to give the intensities of the Zeeman components of the triplet PD multiplet, with special reference to the forbidden lines corresponding to the quantum jumps $\Delta j = 2$ and 3. The theory was tested on the observations made by van Geel (see preceding abs.). C. C. KIESS

The band fluorescence of mercury vapor. S. MROZOWSKI. *Z. Physik* 50, 657-90 (1928).—The excitation conditions and the structure of the Hg fluorescence bands are investigated. Changing structure which accompanies change in the density of Hg vapor is ascribed to reabsorption, but the annihilation of fluorescence at high temp. is probably due to diminished absorbing capacity of the bands. Every spectral line lying in the absorption range of Hg vapor excites the fluorescence but the structure of the spectrum depends on the method of excitation. A plausible assignment of the bands to the 2^3P states of the atom is found and from the convergence limit of the bands the heat of dissociation of the Hg mol. is detd. at about 15 kg. cal. W. F. MEGGERS

The measurement of ultra-violet quanta by fluorescence photometry. WM. T. ANDERSON, JR., AND LESTER F. BIRD. Hanovia Chem. & Mfg. Co., Newark, N. J. *Phys. Rev.* 32, 203-7(1928).—The relative intensities of monochromatic ultra-violet light detd. throughout the ultra-violet Hg spectrum by the use of a fluorescence photometer employing widely different chem. substances check the intensities of the light given by a thermopile. The agreement between the photometric and thermopile measurements indicates that both methods may be employed for measuring accurately the energy in the ultra-violet region. BERNARD LEWIS

The Raman phenomenon in xylene. C. E. BLEEKER. *Z. Physik* 50, 781-6 (1928).—Raman has shown that when liquids are irradiated with Hg light the scattered light contains, besides the original Hg lines, new lines and a continuous spectrum. The new lines are explained by assuming that the incident radiation is partly absorbed by the liquid mols. and partly scattered with modified wave length. The spectra of Hg light scattered by benzene, toluene, xylene and CCl_4 were photographed but results are published for xylene only. The wave lengths and intensities of about 30 lines were measured in the interval 4098 to 6557 A. U. From the wave no. differences between the modified lines and the exciting Hg lines the wave lengths of 16 infra-red absorption bands are calcd. These range from 3.27μ to 303.0μ ; 11 of them, viz., 3.27, 3.42, 4.00, 6.20, 6.47, 6.83, 7.25, 9.05, 9.45, 9.91, 13.65μ agree closely with absorption bands observed in xylene by Coblentz at 3.25, 3.40, 5.25, 6.20, 6.73, 6.86, 7.20, 8.9, 9.5, 9.8μ , 15.6μ . No anti-Stokes lines were found in xylene. W. F. MEGGERS

The Raman effect. PETER PRINGSHEIM AND B. ROSEN. *Z. Physik* 50, 741-55 (1928).—By illuminating with the light of a Hg lamp the spectrum of light scattered in a no. of simple org. compds. is photographed with a glass-prism spectrograph. The compds. studied are CH_2Cl_2 , CHCl_3 , CCl_4 , $\text{C}_6\text{H}_5\text{Cl}_2$, C_2Cl_4 , $\text{C}_2\text{H}_2\text{Cl}_4$, C_6H_6 , $\text{C}_6\text{H}_5\text{Cl}$ and $\text{C}_6\text{H}_5\text{CH}_3$. In each case a no. of modified lines are found in the spectral range 4100 to

5700 A. U. The estd. intensities, wave lengths and corresponding wave nos. of these lines are given and practically every one is assocd. with a particular Hg line. The new lines are explained on the assumption that the incident radiation is partly absorbed by the mols. of the liquids and partly emitted as light of increased (or decreased) wave lengths (Raman effect). The difference in wave no. of the exciting line and the modified scattered line is thought to be the wave no. of an absorption band characteristic of the liquid. Comparison with the infra-red band spectra of the above-mentioned liquids shows that every Raman line can be ascribed to a known infra-red frequency, but not every infra-red band has a Raman line assocd. with it. Anti-Stokes lines are present in considerable no. but decrease rapidly in intensity as their distance from the exciting line increases. The Raman spectrum of SiCl_4 is extremely weak and has no recognizable similarity to that of ClCl_4 . Crystal quartz gave a no. of lines but only part of them can be interpreted with known absorption bands; fused quartz on the other hand, does not give any modified lines in its scattered light. W. F. M.

The Raman effect in highly viscous liquids. S. VENKATESWARAN. *Nature* 122, 506(1928).—To det. the influence of the state of mol. aggregation on the Raman effect observations of the scattering of light from the Hg arc were made with dry glycerol at various temps. and with glycerol- H_2O mixts. of various strengths. The continuous spectrum excited by the line 4358.3 A. U., is very intense with dry glycerol but weakens when the glycerol is heated to 120° . Similarly, in the mixts. with H_2O the continuous spectrum weakens as the proportion of glycerol in the soln. is diminished. C. C. K.

Origin of the electrically excited helium. L. S. ORNSTEIN, H. C. BURGER AND W. KAPUSCINSKI. *Z. Physik* 51, 34-50(1928); cf. *C. A.* 22, 2512.—A vacuum thermocouple was used to measure the intensities of lines emitted by He sources which afforded observations for gas pressures ranging from 0.3 mm. to 40 mm. For sources with pressures of 0.01 to 0.05 mm. photographic methods were employed. The variations in the intensities with current strength and pressure, and with diam. of the capillary of the discharge tubes are shown graphically for the lines 20,582, 7281, 6678, and 5016 A. U. of the singlet system, and 10,830, 7065 and 5876 A. U. of the triplet system. From these results it is concluded that only a part of the emitted light comes from the recombination of electrons with ions; the rest is due to direct excitation or to at. impact. From a comparison of the intensities, for different pressures, of lines representing similar term combinations in the triplet and singlet systems, e. g., $2^3P - 3^1D$ with $2^1P - 3^1D$, etc., it is shown that a selection principle governing electronic impacts holds which is analogous to the selection principle governing radiation. S. L. B. ETHERTON

The mechanism of photo-sensitization and photo-inhibition from the point of view of absorption spectra. B. K. MUKERJI AND N. R. DHAR. *J. Indian Chem. Soc.* 5, 411-5(1928).—The absorption spectra have been photographed of the various constituents of systems which react or are inhibited from reacting in the presence of photocatalysts. The photo-sensitizing reactions examd. include: reduction of Fehling's soln. in the presence of $\text{UO}_2(\text{NO}_3)_2$ and of FeCl_3 ; of oxalic and chromic acids in the presence of MnSO_4 and H_2SO_4 ; CuSO_4 and $\text{K}_2\text{C}_2\text{O}_4$ in the presence of $\text{UO}_2(\text{NO}_3)_2$ and of FeCl_3 . The reactions examd. from the point of view of photo-inhibition include: formic and chromic acids in the presence of MnSO_4 ; oxidation of benzaldehyde in the presence of hydroquinone, and in the presence of phenol. A study of the spectrograms shows that the addn. of U or Fe salts to mixts. reacting photochemically causes an increase in light absorption by the entire reacting system and that in the presence of photoinhibitors no such increase in absorption occurs. C. C. KIESS

Photooxidation of anthraquinone. KARL PFEILSTICKER. *Biochem. Z.* 199, 8-11 (1928).—The exptl. evidence that the 2 carbonyl groups of anthraquinone become reduced under the action of photooxidation leads to the following considerations: The photochem. reaction is considered as the sum of cathodic and anodic phenomena, the mol. group taking up the light acting as the cathode. It may also be regarded as a reaction involving a splitting of H_2O , the H^+ attaching itself to the light-sensitive group. This fundamental reaction requires 1 electron for each H-atom in the electrolysis. According to Einstein one light quantum is needed for the work of the photochem. reaction: $\text{H}_2\text{O} + 1 h\nu \rightleftharpoons \text{H}^+ + \text{OH}^-$. In anthraquinone the light-sensitive carbonyl groups add on H atoms under the influence of quanta, generally 1 atom for 1 quantum, while the corresponding OH groups are taken up by the oxidizable substances. The

oxidation of toluene to benzoic acid can thus be formulated: $3\text{C}_6\text{H}_5 \begin{array}{c} \diagup \text{CO} \\ \diagdown \text{CO} \end{array} \text{C}_6\text{H}_5 + 6\text{H}_2\text{O}$

the presence of free O_2 the anthrahydroquinone is reconverted to anthraquinone and H_2O_2 which can oxidize some of the substances and thus reduce the no. of quanta required for the reaction if it were only photooxidation. It is pointed out that chlorophyll acts similarly to anthraquinone.

S. MORGULIS

The combination of hydrogen and oxygen by electric discharges. ROGER D. RUSK. North Central Coll., Naperville, Ill. *Phys. Rev.* 32, 287-92(1928); cf. *C. A.* 22, 3841.—*Combination of H_2 and O_2 in the Geissler discharge, low-voltage arc and electrodeless discharge.*—It was noted that combination ceased to be explosive in equiv. vols. of the 2 gases at pressures below 3 cm. Logarithmic decrease in pressure was obtained in equiv. vols. in the Geissler discharge for const. current, whereas excess O_2 increased and excess H_2 decreased the rate of combination, a similar change in rate having been noted by Lind (*C. A.* 13, 1183) in α -ray expts. *No. of H_2O mols. formed per pair of ions, as function of pressure.*—From a consideration of the no. of ions present in the Geissler discharge, it appears that the no. k , of H_2O mols. formed per pair of ions at the lower pressure is much less than unity, but that it increases with increasing pressure and may approach Lind's value at somewhat higher pressures. The pressure at which k approximates unity is such that the time between mol. collisions is of the order of magnitude of the life of an excited H atom. This is consistent with the view that combination may be due to some similar type of excitation produced by a process secondary to ionization.

BERNARD LEWIS

"After-effect" in certain photochemical reactions. II. B. K. MUKERJI AND N. R. DHAR. *J. Indian Chem. Soc.* 5, 203 8(1928).—The "after-effect" observed in many photochem. reactions is of common occurrence and is observed in FeSO_4 and I, oxalic acid and I, NaNO_2 and I, the bleaching of dicyanine, Na malonate and I, Na formate and HgCl_2 , Na lactate and I, decompn. of Fehling's soln. in presence of FeCl_3 , CuSO_4 and NH_4 oxalate in presence of FeCl_3 and in the decompn. of K mangani-oxalate. Reaction velocities were measured in hollow transparent quartz cubes kept at const. temp. The most noticeable "effect" appears in the decompn. of K mangani-oxalate. The life-period of activated mols. in photochem. reactions in solns. is considerably prolonged and the slow reversion of activated mols. into the inactive state is the main cause of the phenomenon of "after-effect."

Vessels for radioactive liquids. EUGÈNE LEVOUX. *Fr.* 637,980, Nov. 29, 1926. To prevent contact with the air, vessels for contg. and drawing off radioactive liquids have piston-like stoppers with rubber disks between Al disks of slightly smaller diam.

4—ELECTROCHEMISTRY

COLIN G. FINK

Electric normalizing and annealing. ANON. *Iron Age* 122, 818-21(1928).—The installation of 8 elec. furnaces at the Timken Roller Bearing Co. is described. These include 2 pit furnaces for annealing high-C chrome steel, each rated at 850 kw. and 50 tons capacity; pusher type furnace for normalizing, rated at 700 kw. with capacity of 150,000 lb. per day; 300 kw. double-end furnace for heat treating bar or tube stock; 2 car type furnaces for annealing miscellaneous bar stock—one is 315 kw. and the other 460 kw. Projected installation will raise the connected load from 3600, at present, to 5450 kw.

A. D. SPILLMAN

An improved spark gap generator for high-frequency furnaces. WALTER ROSENHAIN AND FRANK ADCOCK. *Electrician* 101, 395(1928).—The regulation of power input to a moderate capacity Northrup furnace is improved by making the Cu electrodes fixed, and varying the level of the Hg pool. The movable reservoir mentioned by Northrup (*C. A.* 13, 1046) has not been applied; instead, the Hg is connected by a rigid pipe to a reservoir contg. an eccentrically mounted Fe armature. Turning the armature through 90° changes the Hg level by $1/8$ in. (2.2 cm.), which is twice the required range. Higher power can be employed, and less H is consumed.

BENJAMIN MILLER

Electric heat treating. A. N. ORIS. *Elec. World* 92, 979-82(1928).—An abstract outlining a variety of elec. furnaces for heat treatment. Since the cost of heat for most products is about 1% of their value, the difference between fuel and elec. heating, if any, is small enough in most cases to have no appreciable effect on production costs. Any such difference is easily outweighed by any reduction of rejects, or retreats, greater uniformity, and the permitting of higher speed of cutting operations, lower labor cost, facility in handling rearrangements. Several types of furnaces are illustrated.

W. H. BOYNTON

Carboly (tungsten-cobalt-carbide)—a new tool material. SAMUEL L. HOYT. *Gen. Elec. Rev.* 31, 585-91(1928).—A discussion of the characteristics of certain W-carbide tool materials, which have been given the trade name of "carboly." The hardness is between that of natural sapphire and the diamond. Means of measuring its hardness and comparing with other hard materials are outlined. Carboly is featured by low thermal expansion and thermal cond., great chem. stability and retention of strength and hardness at elevated temps. It will take and retain a sharp cutting edge. A no. of unusual applications of carboly as a cutting tool are given. These include making of certain alloys of Cu-Sn-C, commutators of elec. motors consisting of alternate layers of Cu and mica, insulating materials, bakelite, etc.

W. H. B.

Electrochemical reduction of solid electrodes. III. The explanation of the behavior of chromites. KURT FISCHBECK and ERICH EINECKE. *Z. anorg. allgem. Chem.* 175, 335-40(1928); cf. *C. A.* 22, 544.—If a stick of fused synthetic cuprous chromite or ferrous chromite is used as an intermediate electrode, chromic acid is found only in the anolyte. If a stick of natural ferrous chromite is used, chromic acid is found in the catholyte also. But if Hg be substituted for the electrolyte on one side of the electrode, the mineral behaves normally, and chromic acid is formed only when the chromite is anode. It is shown that when the mineral is an intermediate electrode the chromic acid formed at the anode end electroendosmose through the porous electrode under the influence of the potential drop along it. This potential drop is relatively great because natural chromite is a poor conductor. No specific values are given, but a piece having a vol. of 3-4 cc. has a resistance of 20-40 kilo ohms. The resistance is less when the electrode is anode. The resistance decreases with c. d. The pore volume was detd. in 2 ways. The first consisted of driving out the air and measuring it. This gave a value of 0.4 cc. per 100 g. The other value, 0.15 cc. per 100 g., was obtained by weighing a sample in the air-dried condition and after baking at 180°. The sample had first been water soaked, so that the difference in weight gives the vol. The second method is held to be better, as the air held in the capillary pores of the mineral is under pressure. **IV. Reduction of several sulfides.** *Ibid* 341-2.—NiS and CoS were prepd. from the sulfates. The powd. sulfides were placed on a Pb cathode in 2% H₂SO₄ electrolyte. H₂S was evolved, and the metals went into soln. C. d. was varied from 0.5 to 20 milliamps. per sq. cm. Current efficiencies, measured by subtracting the vol. of H from the equiv. vol., decreased with time and with increasing c. d. A Zn blende of unknown origin was powdered and treated in the same way. The cathode gas contained H₂S, and notable Zn ppts. were obtained. The c. d. averaged 10 milliamps. per sq. cm.

BENJAMIN MILLER

Theoretical potentials of sodium, potassium and calcium. PAUL DROSSBACH. *Z. Elektrochem.* 34, 205-11(1928).—D. believes that more reliable values for the potentials of light metals can be obtained by calcn. from thermal data on the basis of Nernst's heat theories, than can be obtained by direct or indirect measurement. This is accomplished for K and Na from thermal data on the chlorides and for Ca from thermal data on the hydrate. The theoretical potentials obtained are as follows: $e_{Na} = -2.52 \pm 0.02$ v., $e_K = -2.73 \pm 0.02$ v., $e_{Ca} = -2.39$ v.

H. SROBARTZ

The behavior of various metals when used as electrodes for alternating current electrolysis. A. P. ROLLET. *Compt. rend.* 185, 457-460(1927).—The metals investigated were polished to a mirror surface, and only one side of the electrode was exposed to the soln. 50 cycle sine wave a. c. was used. The temp. was 20°. The critical c. d. as defined by Shipley and Goodeve (*C. A.* 21, 1597) is independent of the voltage between the electrodes. Though the c. d. be above the critical value, no gas bubbles form unless the voltage between electrodes (e_{max}) is greater than a critical value. This critical voltage is equal to the decompn. voltage in d. c. electrolysis. In general, the c. d.-voltage relation can be graphed as a straight line passing through the origin. But if the electrode area is less than 1 sq. mm. the graph is curved below the critical voltage, and the critical c. d. cannot be exceeded. The critical c. d. increases with the concn. of electrolyte to a limit value, then remains const. The concn. at which this limiting critical c. d. is reached increases with the electrode area, but the limiting

value is const. No explanation is given for these 'area' effects. Limiting critical c. ds. are given for 8 metals in KOH and for Au and Pt in H_2SO_4 . B. MILLER

Investigations on the electrodeposition of silver, with special reference to the use of sodium cyanide. EDWARD B. SANISAR. *Trans. Faraday Soc.* 24, No. 91, 45-55, Preprint(1928).—A study is made of the effect of the different bath constituents on the deposit, and the behavior of Ag-plating solns. contg. NaCN in place of KCN to det. whether the salts are interchangeable or not. A scratch hardness test is employed in which the width of the scratch is measured by a micrometer eye-piece. A loaded diamond is the scratching agent. The hardness

figure = $\frac{1}{\text{breadth of scratch in micrometer divisions}} \times 10,000$. The hardness figures are purely arbitrary, but the hardest deposit has the highest hardness figure, which is in keeping with the usual methods of expressing hardness. The test is applied to det. the change of hardness of deposited Ag with variation in: (1) carbonate content; (2) % excess of free CN; and (3) c. d. Also, to record the effect of using mixts. of NaCN and KCN. Conclusions from the exptl. work are: (1) NaCN may replace KCN and a bath consisting of $AgNO_3$ 35 g./l., NaCN 40.4 g./l., Na_2CO_3 80 g./l. and 100% excess CN gives good, satiny deposits at c. ds. of 0.302 amp./sq. dm. and upwards; (2) increasing carbonate content causes a softening in the Ag deposit; (3) increasing free CN up to 200% excess makes for softer Ag deposits, after which the type of deposit changes and becomes harder, the amt. of free CN largely detg. the hardness of the deposit; (4) variation of c. d. has little influence on the hardness, high values favoring soft deposits; (5) with pure salts good Ag deposits are obtained from baths contg. both Na and K cyanides, but the 2 cyanides should not be used together indiscriminately where there is danger of impurities in the baths. W. H. B.

Electrodeposition of aluminum. D. B. KEYES, SHERLOCK SWANN, JR., W. KLABUNDE AND S. T. SCHICKTANZ. Univ. of Illinois. *Ind. Eng. Chem.* 20, 1068-9(1928).—Al is deposited from low-melting org. compds. using an Al anode and Cu cathode. A smooth coating is obtained at 20° from diethyl aluminum iodide or ethyl aluminum diiodide, the electrodes being 1 cm. apart, c. d. 0.02 amp./sq. cm., and voltage 40, while with a mixt. of tetraethyl ammonium bromide and $AlBr_3$ at 100° with 0.2 amp./sq. cm. and 16 v., the deposit is only partially adherent. An x-ray diffraction pattern of the Al deposit shows that it is made up of small crystals in random orientation, the size being within the range of 10^{-4} - 10^{-3} cm. H. STOERTZ

Stain spotting of cast metals (after plating). W. P. BARROWS. *Metal Ind.* (N. Y.) 26, 397-8(1928).—A progress report of a study of "crystal spots" and "stain spots" which appear on cast metals after cleaning and plating, brass, bronze and malleable or gray Fe castings being employed. It is stated that stain spots may occur on either oxidized or unoxidized finishes, while crystal spots occur only on the finishes which contain S, such as the oxidized finishes or black Ni deposits. Stain spots occur on both lacquered and unlacquered, plated and unplated specimens, while crystal spots occur only on lacquered objects. The presence of humidity appears to be necessary. Conclusion: Stain spots are usually due to pores in the castings, hygroscopic compds. being occluded or formed in these pores by the action of the cleaning, plating or coloring solns. The spotting might be prevented by eliminating pores from the castings, preventing staining compds. from entering into or remaining in the pores, or by excluding moisture from access to the pores after the articles are finished. H. S.

Electrolysis at high current density (ozone). EML. DUHME AND HANS GERDIEN. *Wiss. Veroffentlich. Siemens-Konzern* 7, 304-6(1928).—By pumping intensely cooled H_2SO_4 at high velocity through hollow electrodes it was possible to use a c. d. of 450 amp. per sq. cm. without sparking and surface alteration at the electrodes. A 9% yield of ozone was obtained. The app. is described. B. MILLER

New apparatus for the estimation of electroendosmosis. NIKOLAUS SCHONFELDT. *Wiss. Veroffentlich. Siemens-Konzern* 7, 301-3(1928).—An app. is pictured and described. The soln. to be investigated is floated on glycerol, and the glycerol on concd. $ZnSO_4$ soln., in which are placed the Zn electrodes. The original should be consulted for details. B. MILLER

Investigation on diaphragma. II. Porosity and endosmosis. K. ILLIG AND

N. SCHONFELDT. *Wiss. Veröffentlich. Siemens-Konzern* 7, 294-300 (1928); cf. C. A. 22, 733.—The elec. charges on various diaphragms in KCl and CuSO_4 solns. have been measured with new app. The results show that if the Helmholtz formula is valid the charges on diaphragms decrease as the porosity increases. A simple method for detg. pore vol. is described. B. MILLER

Electrical precipitator for brown coal dust. ANON. *Siemens Z.* 8, 573-81 (1928).—A popular review of the development of the Siemens-Schuckert electrical dust precipitator and of its application to powdered coal driers. Various constructional features and safety devices are described. There are about 400 installations. Drier capacities are increased 10-40%. Purification efficiency is better than 98%. The energy consumption is about 0.05 kw. hr. per 1000 cu. m. BENJAMIN MILLER

Electrical dust precipitation. EDWIN H. LEWIS. *J. West Scot. Iron & Steel Inst.* 35, Part VI, 98-100 (1928).—The gases from a rotary cement kiln are treated with an Oski elec. precipitator. This differs from the Cottrell precipitator in that poorly conducting, reinforced concrete, collecting electrodes are used rather than metallic electrodes. This eliminates loss due to "back ionization." The dust is allowed to accumulate until it falls of its own weight. In addn. to the elimination of electrode-tapping, the power consumption is lowered. The gases must be cooled to about 200° to protect the concrete. This is done by water sprays, from ordinary oil burner nozzles. The power consumption is about 6 watt-hrs. per 1000 cu. ft.; the water consumption is about 1 gallon per 1000 cu. ft. The special electrically-conducting concrete is made from granulated blast-furnace slag, well-burned red ashes and cement. B. MILLER

J. H. MOORE

The production of copper castings having high electrical conductivity. GEORG MASING AND CARL HAASE. *Wiss. Veröffentlich. Siemens-Konzern* 7, 322 (1928). Molten Cu absorbs gases and vapors, especially O and S. Melting under a protective layer of C or slag does not entirely prevent contamination. The purest electrolytic Cu carries traces of electrolyte, so that a certain content of O and S must always be expected in technically melted Cu. This would not be particularly troublesome, were it not for the fact that SO_2 is formed, which escapes during solidification, and causes a porous structure. Since it is practically impossible to avoid SO_2 , it is necessary to get rid of it chemically. P is the preferred reagent, since it is easily handled, its amt. can be readily controlled, does not require high temp. for reaction, and gives castings with a good surface. Its great defect is that it leads to lowered cond. In the effort to improve the cond. castings were made with extremely low P content. The cond. was not improved as much as expected. This was found to be due to the low density, since the same material had much higher cond. after drawing and annealing. Li, Be, Mg, Ca, Al, Si and boron suboxide were tried. Li gave good results, but required extreme care. Be gives good results, but is expensive. Mg, Ca and Al give poor surface. Si is not so good as P, and boron suboxide requires high and controlled temps. The best results were obtained with an alloy of Be 80%, Al 20%. This is much cheaper than pure Be, and as effective. B. MILLER

Electric conduction in hard rubber, Pyrex and fused and crystalline quartz. HERBERT H. RACE. *J. Am. Inst. Elec. Eng.* 47, 788-91 (1928). Polarization and conduction both result in the conversion of elec. energy into heat, producing local and general heating, which may be contributing causes to the progressive deterioration and final break-down of the insulation. The const. potential method described provides a means of studying the inherent voltage-current-time relations which may be masked, where alternating applied potential is employed. The object of the tests was to det. curves of elec. current flow as functions of time, through certain solid dielectrics, after const. potential has been either applied to or removed from opposite faces of a flat plate of the sample. Means of making tests and exptl. results on 4 materials are given. Expts. were conducted with an air gap and with intimate contact. Several curves are included. Peculiar reversals are noted in the charge and discharge curves for fused quartz. W. H. B.

A high-resistance liquid rheostat. ANDREAS GYEMANT. *Wiss. Veröffentlich. Siemens-Konzern* 6, 58-66 (1928). The object of the investigation was to develop a usable rheostat of the order of one million megohms. The final form was a glass tube, 2 cm

in diam., 1 m. long, filled with a soln. of picric acid in a mixt. of benzene and EtOH. With the picric acid content kept at 0.7%, the resistance varied from 0.01 megohm per cm. at 100% EtOH to 1,000,000 megohms per cm. at 100% benzene. The resistance value is permanent if the soln. is protected from air (best by sealing the tube), but small quantities of water lower the resistance. The temp. coeff. changes with the alc. content; it is 0.013 at 100% EtOH, drops to a min. of -0.0252 at 5% EtOH, then rises to 0.024 at 0% EtOH. Ohm's law applies to the highest p. d. used, 4 kv. per cm.

B. MILLER

The electrostatic forces on the filament wires of vacuum tubes. K. POHLHAUSEN. *Wiss. Veröffentlich. Siemens-Konzern* 7, 109-19(1928).—The usual single wire filament of a vacuum tube is the axis of the cylindrical anode. To get high capacity multi-wire filaments are used, the wires being parallel to the axis. With several wires residual electrostatic forces must be considered, whereas the symmetrically placed single wire is force-free. These forces are proportional to the square of the voltage; in high-voltage rectifying tubes they may reach dangerous values, and possibly destroy the filament. Formulas are derived for calcg. these forces in tubes with and without central supports, neglecting end effects. A 100 kv. rectifier, with anode radius 3.75 cm., 10 filament wires of 0.025 cm. radius on a circle of 2.25 cm. radius, is taken as an example. Each filament wire must withstand a force of 2.12 g. per cm. of length. An axially placed support of 0.25 cm. radius increases the force by 7%.

B. MILLER

Direct-current generators of very high voltage. S. R. BERGMAN. *Gen. Elec. Rev.* 31, 596-9(1928).—A novel type of high voltage d. c. generator for use in radio, telegraphy and telephony is described and illustrated. The characteristics of the machine depend upon the fact that the armature reaction is completely neutralized by the compensating winding. There is no distortion of the field flux which leads to the following advantages: (1) no extra load losses due to field distortion; (2) the field may be weakened without any penalty; (3) the machines run without sparking; and (4) the absence of field distortion leads to a stable commutating zone.

Electric firing and stained glass (PEARSON) 10. Electric heating of glass annealing furnaces (TAMEL) 19. Hydrometallurgical laboratory [electrodeposition of Fe] (TRAILL) 9. Electrolytic corrosion prevention of condenser tube corrosives (PHILO) 14. Deposition of rubber (Fr. pat. 638,504) 30. Sugar crystals (Fr. pat. 638,328) 28. Wire for uninsulated electric conductors (Brit. pat. 286,264) 9. Apparatus for producing artificial silk (Brit. 286,086) 23.

Dry cell electric battery. WM. M. TURNLEY. U. S. 1,688,565, Oct. 23. Structural features.

Electric dry cell battery. CHARLES A. GILLINGHAM (to National Carbon Co.). U. S. 1,688,073, Oct. 16. Structural features.

Electric battery with supplementary electrode for indicating fall in level of the electrolyte. E. ELWESS. Brit. 285,622, Jan. 7, 1927. Various structural features are specified.

Storage battery grids. ROBERT L. ELLERY. U. S. 1,687,752, Oct. 16. Structural features.

Storage battery plates. WILLARD L. REINHARDT (to Willard Storage Battery Co.). U. S. 1,688,399, Oct. 23. Plates are treated with a soln. such as glue or "sol. cellulose" which when dry will leave a moisture-excluding coating on the plates and the plates are then heated in an inert gas, e. g., in superheated steam.

Separators for storage batteries. WILLIAM L. KANN. U. S. 1,688,336, Oct. 23. Wood of the Myristicaceae family such as Kwatta wood is used for manuf. of separators. Cf. C. A. 22, 3846.

Cover for storage batteries. COMPAGNIE GÉNÉRALE D'ÉLECTRICITÉ. Fr. 636,309, March 2, 1927.

Insulating ring for storage batteries with bipolar electrodes. COMPAGNIE GÉNÉRALE D'ÉLECTRICITÉ. Fr. 636,304, Feb. 16, 1927.

"Splash-preventing" device for electric batteries. J. STONE & Co., LTD., A. H. M. J. WARD AND S. C. DAVEY. Brit. 285,993, Nov. 25, 1926. Structural features.

Electrolytic rectifier. JAMES K. ELDERKIN (to Forest Elec. Corp.): U. S. 1,689,819, Oct. 30. Structural features.

Cell for electrodeposition of metals. ROBERT D. PIKE, GEORGE H. WEST and BENJAMIN P. LITTLE (West and Little to Pike). U. S. 1,689,597, Oct. 30. A porous diaphragm seps. anode and cathode compartments and a const. level of liquid is maintained in both compartments. Various structural features are described of an app. adapted for deposition of Fe or Zn.

Electrodeposition of metals. SIEMENS & HALSKE A.-G. Brit. 286,457, March 8, 1927. In electrodeposition of metals or alloys from a molten mass on to metallic bodies, a mass is employed having a m. p. at least 100° below that of the article on which the deposition is made. Cr, Ni, Mo, W or the like may be deposited alone or simultaneously with other metals from a molten bath composed chiefly of B compds., sulfates, bisulfates, silicates or cyanides. Cr is deposited on Fe from a mass contg. Cr oxide 15, borax 40 and Na metaphosphate 50 parts, at a temp. of about 950° employing a current of about 1000 amp. per sq. m. of cathode; a Ni compd. may be added to deposit Ni with the Cr.

Apparatus for electrodeposition of metals from circulating electrolyte solutions. I. G. FARBENIND. A.-G. Brit. 285,824, Feb. 21, 1927.

Electrolysis of water. GEORGE FRANCOIS JAUBERT. Fr. 638,346, Dec. 1, 1926. See Brit. 281,674 (C. A. 22, 3591).

Electrolytic production of metals, metalloids or compounds. JEAN LUCIEN ANDRIEUX. Fr. 638,345, Dec. 1, 1926. A fusion bath composed of boric acid or borax with the addn. of fluorides, chlorides or phosphates is used to dissolve oxides of metals or metalloids or other O compds. from which the elements or their borides, or compds. of metals and metalloids may be obtained by electrolysis.

Electrolytic aluminum. SOC. ANON. POUR L'IND. DE L'ALUMINIUM. Fr. 638,465, Jan. 21, 1927. In the production of pure Al from crude or impure Al, solid electrodes in an electrolytic bath of lower m. p. than the m. p. of the cathodes are used. The electrolyte may be halogen compds. or sulfides of Al and of alkali or alk. earth (including Mg) meta's. The electrodes may be alloys of Fe and Si contg. at least 1 atom of Si for 1 atom of Fe.

Electrolytic separation of chromium. CHROM INDUSTRIE MAX WOMMER. Fr. 636,424, June 22, 1927. Salts of feeble acids having a disson. const. less than 10^{-7} are added to the aq. chromate solns. in the electrolytic sepn. of Cr. By this means a change of anions is obtained, the result of which is that the strong acid drives out the feeble acid from its salt and thus lowers the concn. of H ions to a favorable value, so that a sepn. of Cr at relatively feeble current densities becomes possible.

Coating metals with chromium. SIEMENS & HALSKE A. G. Fr. 638,238, July 26, 1927. Large objects are coated electrolytically with Cr bit by bit, the uncoated part being protected by flowing part of the soln. used over it, or enclosing the article in an atm. of H.

Drying electrolytic iron or other corrodible materials. ALBERT PEARSON (to Western Electric Co.). U. S. 1,687,588, Oct. 16. A non aq. solvent such as denatured alc. is added to moist particles of electrolytic Fe or other corrodible materials, the mixt. is agitated and the liquid portion is then withdrawn, and these operations are repeated until the moisture originally present on the particles is replaced by the solvent; the latter is then removed by evapn.

Electrical condenser. ARTHUR J. WEISS (to Dubilier Condenser Corp.). U. S. 1,688,478, Oct. 23. Condenser bodies which may be formed of paper and metal foil are impregnated with a heated insulating material such as melted paraffin and then are immersed while heated in another material such as petrolatum which has a lower m. p. than the material used for the first impregnation, and the condenser is cooled while immersed in the second material.

Continuously loaded electric conductors. OLIVER E. BUCKLEY (to Western Electric Co.). U. S. 1,689,324, Oct. 30. The magnetic properties of a loaded conductor are improved by passing it through a magnetizing coil.

Stifling electric discharges. SIEMENS-SCHUCKERTWERKE G. M. B. H. Fr. 636,520, June 24, 1927. Elec. discharges are stifled or their production is prevented by placing in the probable path of the discharge substances which will remove so large a no. of electrons or ions that the remainder are not sufficient to carry the current. Thus, to prevent an arc in safety fuses with fusible Ag wire, halogens or their compds. may

be used, e. g., I_2O_5 becomes dissocd. at the temp. produced and combines with the Ag ions.

Heating reacting or other liquids by electric current. GUSTAV BAUM (to Niagara Electro Chemical Co.). U. S. 1,688,679, Oct. 23. An elec. conductive liquid such as HOAc and EtOH (to form EtOAc) is passed through ceramic material or other suitable elec. non-cond. structure with multiple channels and elec. current is passed through the liquid to heat it. An app. is described. U. S. 1,688,680 also relates to app. for this purpose.

Apparatus for electrically heating metal bars. ERNEST S. JEFFERIES (one-third to Ebenezer A. W. Jefferies). U. S. 1,689,876, Oct. 30.

Hammer device for removing dust from electrodes of dust precipitation plants. LODGE-COTTRELL, LTD. AND L. LODGE. Brit. 286,390, Dec. 11, 1926.

Direct-humidity recording apparatus. ERNEST B. WOOD (to Western Electric Co.). U. S. 1,689,313, Oct. 30. Various features of elec. app. are specified.

"Synthetic" pig iron. AKTIESELSKAPET NORSK STAAL (ELEKTRISK-GAS-REDUKTION) AND E. EDWIN. Brit. 286,067, Feb. 12, 1927. See Can. 283,386 (C. A. 22, 4102).

Nickel flakes. COMPAGNIE GÉNÉRALE D'ÉLECTRICITÉ. Fr. 638,013, July 5, 1927. Flakes of Ni for addn. to the active mass of elec. storage batteries are made by deposition of layers of Ni alternately with an anodic polarization of their surface, and treating with an acid, e. g., 10% H_2SO_4 which will penetrate the capillary spaces between the layers and sep. them by liberation of H. Fr. 638,014 describes a process for making the flakes in which alternate layers of Ni and Cu are deposited, the Cu being afterwards dissolved out by solns. of ferric salts contg. neither Cl nor free acid. $Fe_2(SO_4)_3$ is preferred, and air, O, persulfates or O carriers such as Ce sulfate.

Hydrogen peroxide. I. G. FARBENINDUSTRIE AKTIENGESSELLSCHAFT. Fr. 636,330, May 6, 1927. The cathodes used for the reduction of O to H_2O_2 are made of non-precious metals or Ag or their alloys having a smooth or polished surface, the conductivity of the electrolyte being assured by using acids or salts which do not attack the metals used. Examples are given of a cathode of polished leaf steel V₂A of Krupp, with an electrolyte of 1% HNO_3 , and of Ag and an electrolyte of 0.7% H_3PO_4 .

Clarifying alcohol. OVIDIO LEONORI. Fr. 636,550, June 24, 1927. Anhyd. alc. is freed from suspended substances, such as metallic carbides used for dehydrating it, by passing through it an elec. current of feeble intensity and low tension, which produces a deposition of the particles on one of the electrodes.

Open electric furnaces. SOCIÉTÉ ÉLECTRO-MÉTALLURGIQUE DE MONTRICHER. Fr. 32,778, Dec. 28, 1926. Addn. to 608,404.

Electric resistance furnace. ROLLO B. LINCOLN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,687,676, Oct. 10. Structural features.

Resistor for electric furnaces. GEORGE M. LITTLE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,687,677, Oct. 16. Resistors are formed of adjacent contacting plates of alternately hard and soft carbonaceous resistor material.

Electric furnace and electrode crane construction. ALBERT E. GREENE. U. S. 1,687,937, Oct. 16.

Electric air-heating furnace. WM. DOHERTY. U. S. 1,688,270, Oct. 16. Structural features.

Electric furnace for annealing metal strips by induction current. MANUEL TAMA. U. S. 1,689,309, Oct. 30.

Working electric annealing furnaces. BROWN, BOVERI & CIE. Fr. 636,414, June 22, 1927.

Steel finishing in an electric arc furnace. ALBERT E. GREENE. U. S. 1,687,936, Oct. 16. A bath of molten steel in the furnace with a covering of slag is prepd. for the finishing treatment; silica sand is then added under an electrode on top of the slag and a carbonaceous reducing agent is added on top of the sand and the mixt. is subjected to the heat of the arc until silica is reduced and the steel underneath is deoxidized and finished.

Mercury-vapor lamps. QUARELAMPEN-GES. Brit. 286,317-8, March 4, 1927. structural features

Mercury vapor lamp. HEINRICH PFERDMENGES. Fr. 638,338, July 27, 1927. In a Hg vapor lamp the irradiation chamber is formed by a U-shaped socket in the luminous bulb and has a tube extending nearly to the bottom. The liquid to be submitted to the action of the rays flows down the tube and returns in the space outside of it acting as a cooling means.

Incandescent electric lamp. RICH HENKEL and HANS WOLFF (to General Electric Co.). U. S. 1,687,496, Oct. 16. Lamps are formed with filaments such as W

and with a filling of a suitable gas such as Ar or Ne contg. also a halogen NH_4 compd., e. g., NH_4Cl , which serves to lessen the chance of short circuiting.

Gas-filled electric incandescent lamp. JAN BERGMANS and THEODORUS J. J. A. MANDERS (to General Electric Co.). U. S. 1,688,777, Oct. 23. Structural features.

Filaments for electric lamps. JACQUES ANTOINE MARIE HAWADIER. Fr. 638,349, Dec. 1, 1926. See Brit. 281,685 (C. A. 22, 3593).

5—PHOTOGRAPHY

C. E. K. MEES

Practical notes on photography. HARRY R. URQUIHART. *Pharm. J.* 120, 416-7 (1928).—Practical notes on aperture and exposure, treatment of too weak or too dense negatives, plates from films, leaf prints, microscopic objects, etc. S. WALDBROTT

Panchromatic photography. "POLYCHROME." *Pharm. J.* 120, 415 6(1928).—Definition of the term, and discussion of methods and detail of manipulation. S. W.

Formation of fine grains in developing. A. LUMIÈRE, L. LUMIÈRE AND A. SEYEWETZ. *Chimie et industrie Special No.*, 501-6(April, 1928).—Reduction in the size of the Ag grains obtained on developing seems possible only provided the original grains of the emulsion are of a definite size, below which $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$ developer cannot modify the dimensions of the grains. The modification in the size of the grains by the developer depends on the nature of the emulsion used. With a rapid Lumière plate (blue label) the following results were obtained: (1) $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$ developer contg. Na_2SO_3 but no alkali gives the finest grains. Developing is rather slow, but can be accelerated without increasing the size of the grains by addn. of borax; greater acceleration is obtained with a small quantity (1%) of Na_2CO_3 , but with slight increase in the size of the grains. (2) Introduction of a Ph or $\text{C}_6\text{H}_4\text{NH}_2$ group in one of the NH_2 groups of $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$ does not modify the above properties; but they do not persist in mono- and dimethyl derivs., which seem to increase the size of the grains. (3) By using borax and a large excess of Na_2SO_3 instead of Na_2CO_3 in metol-hydroquinone and metoquinone developers, the size of the grains can be reduced slightly. (4) Addn. of NH_4Cl to an alk. developer, such as normal hydroquinone or genol-hydroquinone developer, appreciably reduces the size of the grains, but less than does $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$, and in addn. the negative is considerably fogged. With emulsions in which the AgBr grains are appreciably finer than the blue label Lumière plates (rapid micro Lumière plates, slow Lumière plates (red label)) there is no appreciable difference in the results obtained with ordinary alk. developers and with Na_2SO_3 - $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$ developers.

A. PAPINEAU-COUTURE

The sensitizing, ripening substances in gelatin. A. STEIGMANN. *Kolloid Z.* 46, 57-9(1928). By expt. and observation it has been proved that *Thiosinamin*, the halogen silver salt sensitizer, which is active through formation of Ag_2S nuclei, is not present as a natural component of the gelatin raw material. The theory of the formation of Ag_2S nuclei in photographic sensitization is not limited herewith.

L. F. MAREK

Toning of stereoscopic transparencies. OLINDO VERATTI. *Il progresso fotografico* 35, 256-66(1928).—Transparencies for toning are made on chlorobromide plates giving black tones, Ag lactate plates being suitable for ferricyanide toning. It is important to wash thoroughly and dry before toning. Dark browns and reds are obtained with U and transparency is increased by treatment with very weak thiosulfate and Na_2CO_3 , which also stabilizes the image. The U color can be modified by mordanting basic dyes on to it. Good colors are also obtained by toning with Cu, the usual Cu ferricyanide toner being employed. Basic dyes can be mordanted to this tone; the yellow tinge left by Cu is more easily eliminated than the color of the U mordant. Ferricyanide and dichromate bleaching were found unsatisfactory as a mordanting method for basic dyes. To obtain satisfactory mordanting, it is necessary that Ag should be present in addn. to the U or Cu. Single metals by themselves do not act well as mordants.

R. SANSONE

Glycerol and its substitutes [in photographic industry] (DARKE, LEWIS) 27.

Silvering photographic films. PALMIRE HENRI NICOLLE and MAURICE JEAN EDMOND CLAUDE. Fr. 638,556, Dec. 10, 1926. Films are silvered by applying a thin layer of a soln. of the Ag salt used, then reducing either by applying a reducing soln. or submitting the layer to the action of ultra-violet rays.

Photographic developers. I. G. FARBENINDUSTRIE AKTIENGESELLSCHAFT. Fr. 636,478, June 23, 1927. 4-Hydroxyethylamino-1-hydroxybenzene and 4-dihydroxyethylamino-1-hydroxybenzene are used as photographic developers.

Photographic printing layer. I. G. FARBENIND. A.-G. Brit. 286,233, Feb. 28, 1927. Paper or the like is sensitized with a salt of 1,2-naphthoquinone-4-sulfonic acid and is developed (e. g., after exposure under a tracing) with an org. compd. contg. a free amino group (such as aniline hydrochloride or 1-methyl-2,4-diaminobenzene, both of which yield red images, or 1-amino-4-hydroxybenzene, which yields a violet image). Gelatin may be used as a carrier for the sensitive material when placed on glass, paper, celluloid or other support.

Photomechanical printing surfaces. K. H. SCHWIMMER and H. PAWECK. Brit. 286,204, March 3, 1927. In processes such as described in Brit. 273,688 (C. A. 22, 1918), a print of a half-tone positive produced on a film or the like is transferred reversed, before the washing and swelling process, to a glass plate so that all the points detd. for printing are contained in a plane. White or dark patches are thus avoided.

Color photography. R. RUTH and AKTIEBOLAGET SVERIGES LITOGRAFISKA TRYCKERIER. Brit. 285,977, Nov. 23, 1926. In prep. a color-screen film with screen particles of the same optical and phys. qualities as the film base, the latter is superficially softened on one surface only as by a rapidly evapg. liquid applied by rollers and the screen powder is then spread (in a manner described) and the surface is subjected to the action of a blower or suction device to remove non-adherent particles. The film is then passed between pressure rollers of which only the roller in contact with the screen grains is heated.

Color photography. LOUIS DUFAY and COMPAGNIE D'EXPLOITATION DES PROCÉDÉS DE PHOTOGRAPHIE EN COULEURS LOUIS DUFAY. Fr. 32,845, July 24, 1926. Addn. to 619,592. The selection screen obtained by known methods is transformed, after obtaining the photographic image, into a positive synthesis screen, allowing the said screen to be seen by reflection. To make this transformation the colorimetric intensity of the constituent elements of the screen is diminished by washing or by chem. agents.

Filters for color photography. SOC. CIVILE POUR L'ETUDE DE LA PHOTOGRAPHIE ET DE LA CINEMATOGRAPHIE EN COULEURS. Brit. 286,223, Feb. 28, 1927. A color filter interposed between a condenser and film comprises juxtaposed cylindrical tubes through which are circulated solns. of colored salts. The red liquid may contain chromic acid and Co chloride, or KMnO_4 and $\text{K}_2\text{Cr}_2\text{O}_7$; the green may contain Cu nitrate and $\text{K}_2\text{Cr}_2\text{O}_7$; and the blue Cu nitrate and dil. NH_3 or Cr sulfate. A thermo-siphon circulation system may be employed.

Color filter system for color cinematography. C. ALSTRUP and V. JENSEN. Brit. 286,250, March 2, 1927. Optical and structural features.

Cinematography in natural colors. "CHROMO" FILM-GESELLSCHAFT M. B. H. Fr. 637,878, July 18, 1927. A color screen for use in projecting color-record images comprises concentric annular filter sectors sepd. by opaque sectors, one set of filters contg. one more color than the other set.

Optical and color screen system for color photography. MERRILL W. SEYMOUR (to Eastman Kodak Co.). U. S. 1,689,258, Oct. 30.

Color screen for cinematography. J. R. ROBERTSON. Brit. 286,052, Jan. 22, 1927. Screens are used comprising a vacuum chamber contg. a gas and provided with means by which an electron discharge can be passed through the gas so that it acts as a light filter. Gases giving red, blue and green colors may be employed. Various structural details are described.

Projection screen. A. M. MARTIN. Brit. 286,448, Feb. 25, 1927. Hessian cloth is stiffened and coated with a thin layer of distemper and provided with an overlying coating of metallic paint. Waterglass may be used as the stiffening agent and second layers of distemper and metallic paint may be applied.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Some reactions in the evolution flask. SANSEI KITASHIMA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 832-7; English Ed. I, 76-7(1928).—K. studies the transformation of S into H_2S in the so-called "Evolution flask." S may exist in iron as sulfide or sulfate and sometimes as the free element. Expts. have been made to det. to what degree of perfection the element is converted into H_2S . Free S is not attacked

by HCl, when it is present alone, but is attacked by the same reagent in the presence of a large quantity of Fe, giving H_2S . CuS is always attacked by 4-4.5 *N* HCl at room temp. or by 0.3-0.35 *N* boiling HCl; the evolution of H_2S is accelerated by the presence of Fe. Fe-, Cd- and $MnSO_4$ are not reduced, even by boiling HCl in the presence of Fe. Thus, when S is present in the original sample as sulfate or another form not attacked by HCl in the presence of Fe, it remains in the flask as insol. residue, or goes in soln. after the sample has been treated in the evolution method. When S is present in a slowly attacked form, it remains in the residue of the evolution flask, but its quantity is so inconsiderable as to be negligible. A. L. HENNE

Investigation on chain reactions in the halogen group. RAGNAR LYDÉN. Univ. of Helsingfors. *Finska Kemistsamfundets Medd.* 37, 20-34(1928).—The reaction $2KBrO_3 + I_2 \rightleftharpoons 2KIO_3 + Br_2$ takes place directly without the addn. of catalysts, and without the formation of free acid. In the presence of KI the further reaction $2KI + Br_2 \rightleftharpoons 2KBr + I_2$ takes place. With excess KI in excess over $KBrO_3$ the quantity of free I remains unchanged; with excess $KBrO_3$, free Br is formed. The reaction also takes place with $KClO_3$, but does not go to completion. The difference is ascribed to the formation of free acid. HANS C. DUUS

The action of metals on persulfates. OSSIAN ASCHAN. *Finska Kemistsamfundets Medd.* 37, 40-4(1928).—Zinc dust has been found to react with $K_2S_2O_8$ as follows: $KOSO_3OOSO_3OK + Zn \rightarrow KOSO_3OZnOSO_3OK$. The product is cryst. and takes up 6 mols. of H_2O of crystn. The reaction is strongly exothermic. Other metals reacting in the same way are Mg, Zn, Cd, Fe (ous), Ni, and Co, and possibly Be, and Hg (ic). $(NH_4)_2S_2O_8$ reacts the same way, but $Na_2S_2O_4$ takes up the metal and crystallizes with 4 mols. of H_2O . The procedure consists in dissolving the persulfate in water and adding finely divided metal until a temp. rise is no longer noted. After filtration the soln. may be evapd. over a water bath. Expts. are under way to test the reaction with bivalent Mn, Cr, Cu, Ca, and possibly Sn and Pb. H. C. D.

Investigation on the formation of iodates from iodides. RAGNAR LYDÉN. Univ. of Helsingfors. *Finska Kemistsamfundets Medd.* 36, 126-41(1927).—Quant. studies have been made on the reactions which take place when KI is melted with $KClO_4$, $KClO_3$, and $KBrO_3$. The first gives the best yield of iodate when excess iodide is present, although there is a considerable evolution of O_2 . The yields for $KClO_4$:KI ratios ranging from 1:1 to 1:2 vary from 41.67% to 62.01% of the calcd. With $KClO_3$ the best yield, 71.94%, is obtained with a $KClO_3$:KI ratio of 1:2 while a 3:4 ratio gives 57.45% yield. An excess of $KClO_4$ reduces the thermal effect of the reaction. With $KBrO_3$ the yields range from 81.30% for a 1:2 ratio of $KBrO_3$:KI to 69.44% for a 1:1 ratio. This reaction takes place with a smaller heat change than the reaction with the chlorate and the velocity is less. HANS C. DUUS

The chemistry of ruthenium. H. GALL. Tech. Hochschule, Munich. *Z. anorg. Chem.* 41, 1070-1(1928).—A reply to F. Krauss (cf. C. A. 22, 4074). Gall maintains that the blue soln. obtained upon reducing Ru soln. is due to the presence of Ru^{II} and not Ru^I , as is claimed by some. W. C. ERAUGH

Basic carbonate of magnesium. TSUNEKICHI NISHIMURA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 838-72; English Ed. I, 77-80(1928).— $MgCO_3 \cdot 3H_2O$ has been exposed to the atm. for 1 year. Decompn. occurred rapidly at the start, the sample losing a max. of 6.7% CO_2 , but the loss was gradually recovered, becoming 4.3% at the end of the year. Some change in the structural nature of the solid probably occurred. $MgCO_3 \cdot 3H_2O$ was suspended in H_2O , and a rapid current of air passed through. After 15 days, the final stage was reached, the carbonate being transformed into $4MgCO_3 \cdot Mg(OH)_2 \cdot nH_2O$. The same expt. performed with $Mg(OH)_2$ as a starting material yields $3MgCO_3 \cdot Mg(OH)_2 \cdot nH_2O$. Both basic carbonates are perfectly stable in the dry state. A. L. HENNE

Preparation of neutral zinc carbonate. JANIS DAYS. *Acta univ. Latvianis* 18, 539-48(1928).—Attempts to prep. neutral and cryst. Zn carbonate under the conditions and according to the methods of Kraut and St. Claire Deville (pptn. cold of a Zn salt by bicarbonate of Na or NH_4) demonstrate that it is impossible to obtain neutral cryst. products; basic carbonates of variable compn. or a mixt. of basic carbonates and neutral carbonate are obtained instead. Length of contact of the ppt. obtained by means of an excess of alk. bicarbonate with the mother soln. has no influence on the cryst. product. NATHAN VAN PATTEN

Organic addition compounds of calcium chloride and calcium iodide. FREDERICK R. GREENBAUM. *Am. J. Pharm.* 100, 600-1(1928).—The compds. prepd. were addn. compds. with urea and thiourca or their derivs. and they combine as long as both amino groups or at least one of the amino group are not substituted. Starting out

with the well-known pharmaceutical compd., CaCl_2 -urea, called "Afenil," the following addn. compds. were prepd.: CaCl_2 -thiourea, CaCl_2 -hexamethyleneamine, CaCl_2 -thiosinamine, CaCl_2 -urethan, CaCl_2 -antipyrine, CaCl_2 -monoacetylurea (acetylafenil), CaCl_2 -acetylthiourea, and CaCl_2 -monophenylurea. From the CaI_2 compds. the following were prepd.: CaI_2 -urea, CaI_2 -thiourea, CaI_2 -hexamethyleneamine, CaI_2 -thiosinamine, CaI_2 -urethan, CaI_2 -antipyrine, CaI_2 -monoacetylurea, CaI_2 -monoacetylthiourea, and CaI_2 -monophenylurea. These addn. compds. are stable, less hygroscopic than CaCl_2 and CaI_2 ; they possess a definite cryst. shape different from the crystals of CaCl_2 and CaI_2 . They are only formed, when CaCl_2 as well as CaI_2 and the org. compds. are readily sol. in the same solvent. These compds. were prepd. for pharmaceutical purposes with the idea in mind of detoxifying the CaCl_2 and CaI_2 by the addn. of these org. bases.

W. G. GAESSLER

Complex salts of amphoteric hydroxyquinoline derivatives. EDUARD HERTEL AND HANS KLEU. Chem. Inst. Univ. Bonn. Ber. 61B, 1653-4(1928).— CuSO_4 converts 5,7-dibromo-8-hydroxyquinoline into an amorphous ppt. which is changed to a yellow cryst. Cu salt on heating. This salt and its chloro analog dissolve in halogen acids, giving rise to the following salts: $(\text{CuCl}_2):(\text{H} \cdot \text{NC}_9\text{H}_6\text{Br}_2\text{OH})_2 + 2\text{H}_2\text{O}$, light yellow, (I), $(\text{CuCl}_2):(\text{H} \cdot \text{NC}_9\text{H}_6\text{Br}_2\text{OH})_2 + 2\text{H}_2\text{O}$, orange yellow, (II), $(\text{CuBr}_4):(\text{H} \cdot \text{NC}_9\text{H}_6\text{H}_2\text{OH})_2 + 2\text{H}_2\text{O}$, reddish violet, (III), $(\text{CuBr}_4):(\text{H} \cdot \text{NC}_9\text{H}_6\text{Br}_2\text{OH})_2 + 2\text{H}_2\text{O}$, violet, (IV), $(\text{CuI}_4):(\text{H} \cdot \text{NC}_9\text{H}_6\text{Br}_2\text{OH})_2 + 2\text{H}_2\text{O}$, copper red (V). I, II, and V lose $2\text{H}_2\text{O} + 4\text{HX}$ on being heated to 90° ; II and III are more resistant to heat. All 5 salts are decompd. by H_2O .

7—ANALYTICAL CHEMISTRY

W. T. HALL

Physical methods in the chemical laboratory. VIII. Electric titration methods. ERICH THILO. Z. angew. Chem. 41, 1057-61(1928).—The theory and practice of potentiometric and conductometric titrations are described.

W. C. EBAUGH

Micro-analysis. LUIS BERMEJO Y VIDA. Univ. Centrale, Madrid. *Chimie et industrie* 20, 221-2(1928).—An investigation into the *micro-Carius method* for the detn. of Cl in org. compds. carried out on a large no. of compds. (details given in Bosch's Thesis (Madrid)) showed that: (1) The resistance of halogens to elimination from the mol. is inversely proportional to their chem. activity. (2) Increase in the no. of halogen atoms combined to the same C increases the difficulty of removing it, considerable differences existing between the different halogens in this respect. (3) Halogens are easily removed from acid radicals. (4) The above conclusions also hold for aromatic compds., but longer time and higher temps. are required. (5) The removal of halogens from a C_6H_6 ring requires a higher temp. than from side chains. (6) Compds. contg. a halogen and another group substituted in the C_6H_5 nucleus are more easily decompd. than those contg. 2 halogens in the nucleus. (7) In poly-substitution products the time and temp. required decrease with tetra and higher derivs. (8) Presence of NO_2 in the aromatic ring facilitates the removal of the halogen. The *micro-Kjeldahl N detn.* is extremely sensitive and suitable for biochem. as well as for org. chemistry investigations; the indicator was modified to increase the sensitiveness of the titration (details in F. Anadon's Thesis (Madrid)). In the *micro-detn. of C and H*, it was found that at Madrid the straight tubes usually used for the H_2O and CO_2 absorption showed considerable variations in wt. during the spring and summer, but not during the winter; no such trouble was encountered with U-tubes having slightly capillary ends. With the charge recommended by Pregl, difficulty is encountered in the combustion of products with high S contents, but by increasing the proportion of PbCrO_4 satisfactory combustion is obtained, even of CS_2 . By addn. of small quantities of Fe or Ni oxide and of $\text{K}_2\text{Cr}_2\text{O}_7$ and PbCrO_4 fluxes, satisfactory combustion of simple org. and inorg. cyanides, complex cyanides, ferrocyanides, etc., was obtained (details in Mingarro's Thesis (Madrid)). For the *micro-detn. of S* by combustion, investigation of some 20 catalyzers for the oxidation of SO_2 to SO_3 showed that none of them was satisfactory as a substitute for the Pt strips recommended by Pregl (details in Rancano's Thesis (Madrid)).

A. PAPINEAU-COUTURE

Radiometric microanalysis. V. RUDOLF EHRENBERG. *Physiol. Inst., Göttingen. Biochem. Z.* 197, 467-75(1928).—The principle of the method is pptn. of the analyzed substance in conjunction with the radioactive Thorium B which serves as an indicator. After centrifuging, the β -radiation is detd. in an aliquot portion by means of an electrometer. A known vol. of 0.001 N $\text{Pb}(\text{NO}_3)_2$ contg. Th B is treated with a Pb-pptg.

agent (0.001 N K_2CrO_4), and the Th B becomes distributed between the ppt. and fluid in the ratio of the Pb amts. in both. For the detn. of N the following procedure is followed. NH_3 is distd. off in a quartz app. and collected in a 10-cc. flask contg. 5 cc. 0.001 N inactive $Pb(NO_3)_2$. After dilg. to 10 cc. and removal of the pptd. $Pb(OH)_2$ by centrifuging, 0.5 cc. of 0.001 N $Pb(NO_3)_2$ contg. Th B and 0.5 cc. 0.001 N K_2CrO_4 are added to 1 cc. of the supernatant liquid, and after centrifuging again the radioactivity is detd. in 1.0 cc. A standardization is made with known amts. of 0.001 N NH_4Cl , and the quantity of NH_3 N thus measured. The method is also applied for detg. adsorption. Thus, 2 mg. of specially prepd. G are shaken with 2 cc. 0.001 N inactive $Pb(NO_3)_2$, and after centrifuging off the ppt. 0.5 cc. of each active Pb soln. and K_2CrO_4 are added to 1.0 cc. In expts. with 10% gelatin solns. by this method it was found that the adsorption is affected by the preliminary treatment of the gelatin so far as temp. and the duration of action are concerned. An improved type of electrometer is described. For Fe detn. the following method is recommended. Solns. of Fe of a concn. of 5 mg. per l. are pptd. in neutral soln. by a reagent made up of 10 cc. 0.1 N K_2CrO_4 to which a few drops acetic acid and a piece of Th-coated Pt plate are added. The concn. of the Fe must be kept low because of the fact that the activity curve shows no direct proportionality to the amt. of Fe except over a small range. For the detn. of K the method of Kramer and Tisdall is followed at first, but the final stages in the $KMnO_4$ titration are carried out again in accordance with the radiometric procedure. An application to the formol titration as well as to the C detn. is also described.

S. MORGULIS

Perchloric acid. General data concerning its various forms. G. FREDERICK SMITH. Univ. Ill. *Chemist-Analyst* 17, No. 4, 20-21 (1928). The fact that the 72.4% const. boiling $HClO_4$ is not dangerous to handle and is particularly suitable for many analytical operations is pointed out; a brief and incomplete bibliography of some important applications is given and methods for testing are outlined. W. T. H.

β -Methylumbelliferone as a fluorescent indicator. C. BULOW AND W. DICK. Univ. Tübingen. *Z. anal. Chem.* 75, 81 (1928). This compd. is easily prepd. from resorcinol and acetoacetic ester. In aq. acid solns. it is colorless but in alk. solns. it shows a blue fluorescence. The color change occurs at pH 6.7. The fluorescence is also shown under the light of a quartz lamp. The indicator can be used in solns. which are of themselves colored sufficiently to interfere with the use of the usual indicators with which a change of color without fluorescence takes place. W. T. H.

Two new methods of potentiometric titration. ERICH MÜLLER AND HERBERT KOGERT. Inst. Elektrochem. der Sachs. Techn. Hochschule. *Z. physik. Chem.* 136, 446-50 (1928).—The first method described is applicable to rapid work where no great accuracy is desired. If the soln. from a buret is allowed to enter the mechanically stirred soln. so that it is immediately forced upon one of the electrodes, there is established soon a condition of over-titration at this electrode while the e. m. f. of the secondary electrode, which is of the same metal, is that of an under-titrated soln. Just before the end point the e. m. f. between the 2 electrodes becomes suddenly greatly diminished. The second method is the same in principle as methods which have been used by Pinten and by Kamiński, although this fact was not known until this paper had been printed. One electrode is a wire wound around the stirrer and the other electrode is a wire at the bottom of the titration vessel. In this case, there is a max. throw of the galvanometer needle at the end point. These methods are probably inapplicable for accurate oxidimetric titrations but work well for the titration of Pb with ferrocyanide, halogenide with Ag and for the titration of acids and bases in the presence of quinhydrone. W. T. H.

Use of monometallic electrode pairs for potentiometric titrations. ERICH MÜLLER AND HERBERT KOGERT. Inst. elektrochem. und physik. Chem. Dresden. *Z. physik. Chem.* 136, 437-45 (1928). In non-reversible reactions such as the titration of Fe^{++} with dichromate or permanganate, arsenite with $KBrO_3$, I_2 with $Na_2S_2O_3$, etc., the simplest method yet described for detg. the end point electrometrically is to take 2 pieces of Pt foil of about 3 sq. cm. area, platinize one by depositing Pt upon it and heating until the deposit turns gray, and connect them by wires through a millivoltmeter (of 30 millivolts throw on either side and an internal resistance of about 3228 ohms) and a suitable resistance. The max. difference in the e. m. f. between the 2 electrodes is obtained at the end point. The end point is easier to find than when bimetallic electrodes are used as recommended by Roberts and Hostetter or by Willard and his co-workers. W. T. H.

A new reagent for potassium, ammonium, rubidium and cesium ions. T. GASPAR Y ARNAL. *Anales soc. españ. fis. quim.* 26, 184 5 (1928).—A soln. contg. equiv. quanti

ties of Na_2CrO_4 and $\text{UO}_2(\text{NO}_3)_2$ is very sensitive to K^+ , with which it forms a yellow ppt. Rb and Cs react similarly, the soly. of the ppt. increasing from K to Cs. NH_4 also ppts., but can be detected otherwise. E. M. SYMMES

Desiccators (anhydrous barium perchlorate-Smith). Its use as an economical drying agent and ammonia absorbent. G. FREDERICK SMITH. Univ. Ill. *Chemist-Analyst* 17, No. 4, 21-22(1928).—References to the literature, method of prep. the reagent, comparison with CaCl_2 as a drying agent and methods of testing are given. W. T. H.

Preparation of stable ammonium molybdate solution. J. P. MEHLIG. Oregon State Agr. College. *Chemist-Analyst* 17, No. 4, 6(1928).—Dissolve 380 g. of MoO_3 in 550 cc. of concd. NH_4OH and 1030 cc. of water. Place this soln. in a separatory funnel and allow it to drop very slowly through a filter paper into 6 l. of 6 N HNO_3 , which is being stirred continuously. Such a soln. has been kept 7 months without deterioration. W. T. H.

New reagents for the determination of small quantities of free chlorine. KNUT ALPHTAN. *Finska Kemistsamfundets Medd.* 36, 109-12(1928).—One cc. of 0.1% of dimethyl-*p*-phenylenediamine-HCl is added to 100 cc. of the water to be tested. The acidity of the sample may range from 5 to 25 cc. 0.1 N HCl per l. One cc. of 0.0115% methyl red (Kahlbaum) in 100 cc. acidified water gives the same color as 0.01 mg. Cl in 100 cc. water with the new reagent. The analysis is carried out by taking 100 cc. water in a glass cylinder, acidifying with 2 cc. 0.1 N HCl, adding 1 cc. of the reagent, and letting the soln. stand 2 min. Methyl red (1.15% soln.) is then added to a similar cylinder until the 2 give the same color. Cl to a min. of 0.01 mg./l. may be detd. HANS C. DUUS

Carbon and hydrogen determinations using a metal tube. S. AVERY. Univ. Neb. *Ind. Eng. Chem.* 20, 1232-4(1928).—A Cu tube protected by an outer jacket of Ni is non-breakable, durable and inexpensive. Water jackets at the ends of the tube protect the stoppers. A series of combustions of typical substances indicates that precise results can be obtained in a minimum time with the Cu tube. W. T. H.

Some notes on the determination of aluminum with special reference to the use of hydroxyquinoline as a reagent. N. SINGLETON. *Chem. Age* (London), Monthly Met. Sect. 19, 25-6(1928). W. T. H.

Quantitative separation of barium and calcium. MME. M. AND M^r. LEMARCHANDS. *Compt. rend.* 187, 601-3(1928). At 100°, 12-30 mg. of BaSO_4 dissolve in 1 l. of water, depending upon the grain size of the sample. The soly. of BaSO_4 in HCl solns. increases with the content of HCl but not proportionately. The solvent action of CaCl_2 is much less and is practically the same between 0.1 and 0.3% content. If a soln. contains 0.039 g. of H_2SO_4 , and 1 g. of HCl, when a ppt. of BaSO_4 is formed at 100°, soly. detns. indicate that 7.6 mg. of BaSO_4 will remain in soln. W. T. H.

Determination and separation of bismuth with cupferron. A. PINKUS AND J. DERNIES. Univ. Brussels. *Bull. soc. chim. Belg.* 37, 267-83(1928).—Soly. measurements indicate that cupferron and Bi give a ppt. practically insol. in H_2O or mineral acids of moderate concn., whereas many cations ppt. with cupferron only in neutral or very weakly acid solns. The sepn. and detn. of Bi consist in pptg. this metal with an excess of cupferron in HCl or HNO_3 soln., oxidizing the ppt. by moderate calcination and weighing as Bi_2O_3 . This procedure may be used in the presence of Cl or SO_4 ions. The sepn. of Bi from Na, K, NH_4 , Cd, Zn, As, Al, Mn, Cr, Ni, Ag and Pb is quant.; the same must be true with quinquevalent Sb, Co^{++} and Hg^{++} . All these metals may be titrated by the customary methods in the filtrate and washing waters, without removal of the cupferron excess. Pb and Cd are quantitatively pptd. by an excess (1.5) of cupferron in neutral solns. This property could probably be used in the Cd-As and Cd-Sb sepn. A. L. HENNE

Standard methods of analysis of pure copper. A. E. LEIGHTON. *Australia Dept. of Defence Munitions Supply Board*, May 1926, 11 pp.—"Procedure A." Dissolve 10 g. of metal in 70 ml. of "stock acid" (350 ml. of concd. HNO_3 dild. to 1250 ml. and added slowly to 500 ml. of concd. H_2SO_4). Evap. to fumes, dil. to 180 ml. and electrolyze overnight with 1 amp. per sq. dm. After 15 hrs. reduce the current to 0.5 amp. and as soon as H_2 begins to be evolved, reduce to 0.4 amp. Finish as usual and weigh the deposit. "Procedure B." Dissolve 5 g. of sample in 42 ml. of the "stock acid," drive off nitrous fumes, dil. to 150 ml. and electrolyze. *Modification of Procedure B when considerable As or some Sb, Te, Bi or Ni is present.*—Dissolve 5 g. as above but evap. the soln. to fumes, add 70 ml. of water and 3 ml. of $\text{Fe}(\text{NO}_3)_3$ soln. contg. 0.03 g. of Fe. Ppt. with an excess of NH_4OH , filter and wash. Conc. the filtrate to a small vol. and repeat the pptn. of the Fe, dissolving the first ppt. in dil. H_2SO_4 . Make the

combined filtrates slightly acid with H_2SO_4 , add 3 ml. of concd. HNO_3 and electrolyze as above in a vol. of 150 ml. Instead of this procedure, when traces of As and Bi are present but not enough Se and Te to interfere, it is recommended to ppt. Se and Te in the H_2SO_4 soln. obtained as above by boiling with SO_2 , igniting the ppt., extracting the ash with 2 ml. of concd. HNO_3 and adding this soln. to the original filtrate and then electrolyzing. In this case no Fe is added to the soln. and there is no ammonia pptn. Or, if As is the only interfering element, dissolve the sample in 66 ml. of "stock acid" instead of 42 ml. and continue as in "B." *Detn. of As, Sb and Sn.*—Two methods of attack are suggested. (a) Dissolve 50 g. in 200 ml. of concd. HNO_3 , added in small portions. Boil off fumes and evap. 15 min. in a l. beaker uncovered, heating on the hot plate. Cool and dil. to 300 ml. (b) Dissolve 100 g. in 400 ml. of concd. HNO_3 . Boil off fumes, cool and dil. to 300 ml. In either case, neutralize with NH_4OH until enough basic Cu salt has formed to cover the bottom of the beaker. Add an aq. soln. of 5 g. ferric alum and dil. to 500 ml. for each 50 g. of Cu. Boil 30 min., dil. to 1.5 l. for 100 g. Cu or to 0.75 l. for 50 g. Cu. Allow the ppt. to settle and filter. Pass the filtrate through a second filter or, when more than 0.002% of As is present, add 1 g. more of ferric alum and ppt. as before. Dissolve the ppt. in hot 6 N H_2SO_4 , reppt. with NH_4OH in a small vol. and filter through the original filter. To recover traces of As, add this filtrate to that originally obtained, make acid if necessary, reppt. with NH_4OH and filter through the same paper. In this way an Fe ppt. is obtained on which all of the Fe and Sb should be adsorbed. *Detn. of As.*—Dissolve the $\text{Fe}(\text{OH})_3$ ppt. in HCl, add Cu_2Cl_2 and KBr together with additional FeCl_3 , distil off AsCl_3 and titrate As iodometrically in the distillate. *Detn. of Sb.*—Dil. the HCl soln. obtained from the AsCl_3 distn. until the HCl concn. is about 2 N, sat. the soln. with H_2S , filter, subject the Sb_2S_3 ppt. to the usual purification and finally weigh as Sb_2O_3 . If, however, Sn is present, take the second Sb_2S_3 ppt., which has been freed from members of the Cu group, and boil it with 100 ml. of oxalate soln. (5 g. oxalic acid and 5 g. $(\text{NH}_4)_2\text{C}_2\text{O}_4$ in 100 ml. of water) until dissolved. Treat the residue with HF in Pt crucible and digest the residue now obtained with fresh oxalate soln., adding this extract to that originally obtained. Boil and sat. with H_2S . Use the filtrate for the Sn detn. and ignite the Sb_2S_3 to Sb_2O_3 , using concd. HNO_3 to assist the oxidation. *Detn. of Sn.*—Boil off the H_2S and electrolyze the oxalate soln. for Sn. Or, the filtrate from the Sb_2S_3 sepn. can be evapd. with an excess of H_2SO_4 to remove oxalate and the Sn then pptd. as sulfide and weighed as oxide. *Detn. of Pb, Fe, Zn, Ni and Co.*—Dissolve 50 g. in 320 ml. of "stock soln." Evap. to fumes, dil. to 700 ml. and electrolyze at 5 amps with a rotating cathode. Reserve the anode for the Pb detn. After the Cu has all been deposited, evap. the soln. and heat the residue till most of the NH_4HSO_4 formed is decomposed. Add 10 drops of concd. HCl, and 50 ml. of water. Sat. with H_2S , filter and wash with H_2S water. Heat to boiling and again sat. with H_2S . Reject these sulfide ppts. unless a check is desired on the Sb detn. *Detn. of Pb.*—After suitable drying, weigh the anode obtained above. Dissolve the PbO_2 , etc., in 100 ml. of 4 N HNO_3 contg. some H_2O_2 . Evap. to 50 ml. and add 120 ml. of "lead acid" (see analysis of aluminum metal) and take to fumes. Cool, filter into a Gooch crucible, ignite and weigh as PbSO_4 . *Detn. of Fe.*—Conc. the filtrate obtained in the preliminary sepn., add Br_2 , boil off the excess, add 5 g. of NH_4Cl and ppt. the Fe as hydroxide. Ignite and weigh as Fe_2O_3 . *Detn. of Zn.*—In the filtrate from the Fe detn., ppt. the Zn as sulfide from acid formate soln., ignite and weigh as ZnO . *Detn. of Co and Ni.*—Electrolyze the filtrate from the Zn detn. for Ni and Co after adding NH_4OH and $(\text{NH}_4)_2\text{SO}_4$ from ammoniacal sulfate soln. Weigh the deposit and dissolve it in 7.5 N HNO_3 . Add 5 ml. of H_2SO_4 , evap. to fumes, dil. to 200 ml., neutralize with NH_4OH , add 5 ml. of HCl and ppt. the Co as the nitroso- β -naphthol salt. Ignite and weigh as Co_3O_4 . *Detn. of Bi.*—Dissolve 50 g. in 200 ml. of concd. HNO_3 , expel nitrous fumes and dil. to 1 l. Add $\text{Fe}_2(\text{SO}_4)_3$ and 5 ml. of satd. $(\text{NH}_4)_2\text{HPO}_4$ soln. Heat to boiling and filter. Dissolve the ppt. in hot 6 N H_2SO_4 , reserving the filter. Dil. and sat. with H_2S . Filter through the same filter and extract the members of the Sn group by treatment with $(\text{NH}_4)_2\text{S}_2$ soln. Dissolve the residual sulfides in 2 N HNO_3 and reject any residue. Make alk. with NH_4OH and add KCN. Again sat. the soln. with H_2S , filter and dissolve the washed ppt. in 2 N HNO_3 . Det. the Bi colorimetrically by the iodide method. *Detn. of P.*—Using 3 g. of sample dissolved in 25 ml. of HNO_3 and 10 of HCl, carry out the Handy method of alkalimetric titration of a phosphomolybdate ppt.

Low's short iodide method for copper, modified. H. F. BRADLEY, *Chemist Analyst* 17, No. 4, 14(1928).—Moisten 0.5 g. of ore with a few drops of water, add a little KClO_3 if sulfides are present, and decompose with 5 cc. of concd. HNO_3 and a few drops of HCl. Digest 5 mins. and if brown fumes are evident, add a few drops

of HCl-H₂O, mixt. Add 7 cc. of concd. H₂SO₄ and boil to copious fumes. Cool, add 3 cc. of water and cautiously introduce 123 cc. of concd. NH₄OH. Add to this slightly acid soln. a concd. NH₄OAc soln. (made by mixing equal vols. of concd. NH₄OH and glacial AcOH) until the red color of Fe(OAc)₃ appears and then add 5 cc. in excess. Cool, add 0.5 g. of NaF, stir till the red color disappears, add 3 g. of KI, stir till dissolved and titrate as usual.

W. T. H.

Simultaneous determination of iron, copper and arsenic by potentiometric titration. E. ZINTL AND F. SCHLOFFER. *Z. angew. Chem.* 41, 956-60(1928).—In an atm. of CO₂, good electrometric end points are obtained, in the absence of HCl or HNO₃, and in the presence of 2-15% H₂SO₄, for the reduction of Fe⁺⁺⁺ to Fe⁺⁺ and of Cu⁺⁺ to metallic Cu by titration with CrSO₄ soln. The presence of quinquivalent As has no effect on the titration but the presence of Sb make it harder to recognize the Cu end point. If not more than 5 mg. of Sb is present the titration is not seriously affected in a vol. of 200 cc. For the detn. of tervalent As, bivalent Cu and tervalent Fe, first boil a short time under CO₂ to remove dissolved O₂, then add a measured excess of K₂Cr₂O₇ to the soln. contg. 5% of H₂SO₄, and titrate with 0.1 N CrSO₄. Three sharp end points are obtained, the first corresponding to the reduction of the excess Cr₂O₇⁻⁻⁻ to Cr⁺⁺⁺, the second to the reduction of the Fe⁺⁺⁺ to Fe⁺⁺ and the third to the reduction of Cu⁺⁺ to metal. The advantage of this method of titration is shown by the fact that the following procedure gives the Fe and Cu contents of a sample of pyrite within an hour. Dissolve 0.5 g. of finely powd. pyrite and 10-20 g. of K₂S₂O₈ by heating carefully in a 100 cc. Kjeldahl flask with 20 cc. of concd. H₂SO₄. Heat first with a very low flame to avoid wasting the persulfate. After 5 min. gradually raise the temp. so that at the end of 10 min. the b. p. is reached. Cool, dil. with water to 200 cc. and boil under CO₂ for a min. Then titrate with CrSO₄ under potentiometric control.

W. T. H.

Determination of manganese in steel, with a note on sampling. WM. F. POND. *Chemist-Analyst* 17, No. 4, 11(1928).—Mn-steel is so hard that it is difficult to obtain good samples. The steels can be obtained in thin plates by pouring some of the melt into cold water. Then by grinding off the oxidized surface and hammering, suitable fragments, the size of a match head, can be obtained. The method described is the well-known bismuthate procedure.

W. T. H.

Standard methods of analysis of pure nickel. A. E. LEIGHTON. *Australia Dept. of Defence Munitions Supply Board*, May, 1926, 6 pp.—"Procedure A." *Detn. of Si.*—Dissolve 5 g. in 50 ml. of HNO₃ and continue as in the Drown method for analyzing Fe and steel for Si. *Detn. of Cu.* Introduce H₂S into the filtrate from the SiO₂ detn., filter, wash and weigh as CuO. *Detn. of Co.*—Boil the filtrate from the CuS pptn. to expel H₂S, dil. to 500 cc. and take 50 cc. for the Co detn. Neutralize with NH₄OH and add 100 ml. of 10 N NH₄OH in excess. Add 3 g. of (NH₄)₂SO₄ and electrolyze at 40° with 3 amps. and a rotating electrode. Dry and weigh the deposit of Ni and Co. Dissolve in 7.5 N HNO₃, add 5 ml. of concd. H₂SO₄ and evap. to fumes. Cool, dil. to 200 ml., neutralize with NH₄OH and add 5 ml. of strong HCl. Heat to boiling and add 2 ml. of nitroso-β-naphthol soln. (2 g. in 75 ml. of glacial AcOH, dild. with 75 ml. of water). Filter, wash with dil. HCl and then with water, ignite carefully and weigh as Co₂O₃. *Detn. of Fe.*—Take 400 ml. of soln. from which the Cu has been removed, ppt. three times with NH₄OH in the usual way and weigh as Fe₂O₃. "Procedure B." *Detn. of Si.*—Treat 5 g. of metal with 50 ml. of 6 N HNO₃, add 30 ml. of HCl, evap. to dryness and continue in the usual way. *Detn. of S.*—Heat the filtrate from the Si detn. to boiling and ppt. with BaCl₂, etc. *Detn. of C.*—The dry combustion method is recommended.

W. T. H.

A micro-chemical method for the detection of potassium as potassium picrate. DR. OLURSEN. *Mikrokosmos* 22, 15-6(1928); cf. C. A. 20, 3716.—K is easily identified by the instantaneous formation of characteristic crystals of C₆H₅(NO₂)₃OK when plants or their sections are treated with satd. solns. of picric acid in 96% EtOH; the ash of plant material is easily tested with the same reagent; Na, Ca and NH₄ do not interfere with the test since the difference in the cryst. structure of these picrate salts is easily distinguishable. A list of plants, the fruits, leaves, stems, etc., of which were tested in this manner, is given.

N. A. LANGE

Investigations into the analytical chemistry of tantalum, columbium and their mineral associates. XIII. New method for the separation of zirconium and hafnium from tantalum and columbium. W. R. SCHÖLLER AND E. F. WATERHOUSE. Sir John Case Techn. Inst. *Analyst* 53, 515-20(1928).—One method is based on the pptn. of the oxalo-earth acids by tannin in weakly acid soln., zirconyl oxalate remaining dissolved (Method A). A second method is based upon the fusion of the mixed oxides with

K_2CO_3 , a procedure which has been perfected so that a single fusion may be sufficient for the sepn. of the bulk of the earth acids. The fusion can be used as a sensitive test for detecting traces of earth acids in zirconia (Method B). To carry out Method A, fuse the mixed oxides with $K_2S_2O_7$ in a silica crucible and dissolve the melt in a satd. soln. of $(NH_4)_2C_2O_4$ contg. about as much of this salt as the wt. of $K_2S_2O_7$ taken. To the boiling soln., add 0.2 g. of tannin dissolved in hot water and introduce 7.5 N NH_4OH dropwise until the discoloration of the ppt. indicates incipient co-pptn. of Zr. Pure Zr salt gives a white tannin ppt. The main ppt. will be yellow, orange or red according to the ratio of Ta:Cb. Allow the liquid to settle in a warm place, filter and wash with 2% NH_4Cl . Ignite the ppt. in the same crucible as that used for the pyrosulfate fusion. To obtain a ppt. free from Zr, repeat the treatment but with less pyrosulfate and less oxalate. Then for the pptn. of the sulfate-oxalate soln., which should not exceed 50 cc. in vol., add dil. NH_4OH while boiling, stopping as soon as a cloudiness is perceptible. Then add just enough 6 N HCl to clear the soln., 1 g. of NH_4Cl and some freshly prepared 1% tannin soln. Add the tannin in small portions, stopping as soon as the soln. is decolorized, which usually requires less than 10 cc. After standing 2 hrs. at 50–70°, filter, wash, ignite and weigh as $(Ta,Cb)_2O_5$. All the reagents must be free from Ca salts as otherwise a ppt. of CaC_2O_4 will be formed in the original oxalate soln. If this appears, filter before neutralizing. In Method B, fuse the mixed oxides with 6 times as much K_2CO_3 in a Pt or Au crucible. Digest the melt with 1 g. of KOH and enough water to cover the melt, heating the contents of the covered crucible for 2 hrs. on the hot plate. Transfer to a small beaker, add filter-paper pulp and filter. Wash the ZrO_2 residue with 2% K_2CO_3 soln., ignite and weigh. If heavy, and derived from a mixt. rich in Ta_2O_5 , repeat the above treatment. Make the final K_2CO_3 soln., from which all ZrO_2 has been removed, acid with HCl and boil with a slight excess of NH_4OH . Filter, ignite strongly and weigh as $(Ta,Cb)_2O_5$. Ignite the above impure ZrO_2 in a Pt crucible, moisten with dil. H_2SO_4 and dry. Fuse with $K_2S_2O_7$ and dissolve in oxalate soln., etc., as in the other method. W. T. H.

Standard methods of analysis of pure tin. A. E. LEIGHTON. *Australia Dept. of Defence Munitions Supply Board*, May 1926, 4 pp. *Detn. of Sb.*—Dissolve 5 g. of metal in 50 ml. of aqua regia. Add 5 g. of tartaric acid and heat to dissolve it. Neutralize with 40% $NaOH$, adding a slight excess. Add 20 ml. of Na_2S soln. (sat. 100 ml. of 20% $NaOH$ with H_2S and mix with an equal vol. of 20% $NaOH$). Filter and wash the ppt. Dissolve the sulfide ppt. in the original beaker with HCl and a little $KClO_3$. Boil off Cl , add 0.5 g. of tartaric acid and treat with $NaOH$ and Na_2S . Filter and unite the 2 filtrates. Add HCl just short of the quantity necessary to ppt. the sulfides of Sn and Sb and boil down to 300 cc. Add 150 ml. of concd. HCl and warm to dissolve the SnS_2 . Sat. the soln. with H_2S , filter and wash the Sb_2S_3 ppt. 3 times with 25% HCl . Transfer the ppt. to a beaker, dissolve it in concd. HCl , boil off H_2S , dil. with an equal vol. of hot water and titrate hot with 0.05 N $KBrO_3$ soln. using methyl orange as an indicator. *Detn. of Pb.*—Dissolve the sulfides obtained in the Sb detn. in as little concd. HCl as possible. Add 120 ml. of "lead acid" and continue as described in the analysis of metallic Al. *Detn. of Bi.*—Neutralize the filtrate obtained on filtering off the $PbSO_4$ in the Pb detn. with NH_4OH , make acid with HCl and ppt. with H_2S . Dissolve the ppt. in HNO_3 , filter if necessary, and ppt. the Bi by adding NH_4OH and $(NH_4)_2CO_3$. Filter and reserve the filtrate for the Cu detn. Wash the Bi ppt. into a crucible with 6 N HNO_3 , evap. to dryness and weigh as Bi_2O_3 . *Detn. of Cu.*—Neutralize the filtrate from the Bi detn. with HCl and ppt. the Cu by adding H_2S . Filter, wash, ignite and weigh as CuO . Dissolve in dil. HNO_3 , filter, nearly neutralize with NH_4OH , add HCl , sat. with H_2S , filter, ignite and weigh. As a check ignite and weigh the residue obtained after dissolving the first CuO in HNO_3 . *Detn. of Fe.*—Take the filtrate from the first H_2S pptn. on the detn. of Bi, oxidize with HNO_3 , add NH_4Cl , make ammoniacal, filter, ignite and weigh the Fe_2O_3 . W. T. H.

Determination of vanadium in steel. F. IBBOTSON. *Univ. Sheffield. Analyst* 53, 531(1928).—The method of Evans and Clarke (*C. A.* 22, 4081) gives good results with an alloy steel contg. Cr, Mo, W, Ni and Co but when much Ni is present the method is difficult because the filtration of the $Ni_2(Fe(CN)_6)_3$ is practically impossible. If, however, the Ni is not removed, a ppt. of Ni and V ferrocyanides is less difficult to filter. W. T. H.

Standard methods of analysis of white metal alloys. A. E. LEIGHTON. *Australia Dept. of Defence Munitions Supply Board*, May 1926, 7 pp. *Detn. of Sn.*—Dissolve 10 g. of metal in 100 ml. of concd. HCl which has been satd. with Br without boiling. When all the metal has dissolved, boil off excess Br, add 300 ml. of concd. HCl and dil. to 1000 ml. Take 20 ml. of the soln., add 100 ml. of concd. HCl and 200 ml. of water and

titrate the Sn iodometrically after reduction with Sn in the usual way. *Detn. of Pb.*—In a Kjeldahl flask, digest 1 g. of metal drillings with 20 ml. of H_2SO_4 . Cool, add 40 ml. of water and boil a few mins. Filter through a Gooch crucible but retain as much of the ppt. as possible in the flask. Add 10 ml. of concd. H_2SO_4 and boil 15 min. Cool, add 30 ml. of water and filter. Ignite and weigh as PbSO_4 . Weigh the residue insol. in NH_4OAc . *Detn. of Sb.*—Heat the filtrate from the PbSO_4 detn. and add a measured excess of standard KMnO_4 . Shake 1 min. and titrate the excess with standard ferrous soln. *Detn. of Cu.*—To the soln. after the Sb detn., add 10 g. of tartaric acid and NH_4OH to alk. reaction. Add 2 ml. of H_2SO_4 and heat nearly to boiling. Add 2 g. of $\text{Na}_2\text{S}_2\text{O}_8$ and 10 ml. of 10% KCNS soln. Filter and dissolve the washed ppt. in 40 ml. of 10% NaOH . Heat to 50° and titrate with standard KMnO_4 soln. *Detn. of Pb. Alternate Method.*—Dissolve 1 g. of sample in 20 ml. of aqua regia, add 2 g. of tartaric acid and 10 ml. of concd. H_2SO_4 , evap. to fumes, dil. with 50 ml. of water, allow to stand and filter. Weigh as PbSO_4 . *Detn. of Fe.*—Dissolve 1 g. in 40 ml. of concd. HCl and a little KClO_3 . Dil. the soln. to 200 ml. with cold water and sat. with H_2S . When the Ca and Pb are pptd. add an excess of NH_4OH and continue passing in H_2S . Filter, wash the ppt. and discard the filtrate. Dissolve out the FeS from the ppt. by treatment with hot 2 N HCl . Filter and dil. to make 0.2 N in HCl . Sat. the soln. again with H_2S and filter. Oxidize the filtrate and ppt. as $\text{Fe}(\text{OH})_3$, etc. If Al is present, carry out the NaOH sepn., finally reprecip. with NH_4OH . *Detn. of Ni.*—Dissolve 1 g. in 20 ml. of aqua regia and evap. off all HNO_3 . Dil. with 25 ml. of cold water and add 3 g. of tartaric acid. Then ppt. the Ni as the dimethylglyoxime compd. with the usual precautions. *Detn. of As.*—Treat 5 g. of metal with 25 ml. of H_2SO_4 and conc. to a paste. Add 200 ml. of water, cool and add 50 ml. of concd. HCl . Cool and filter through asbestos. Warm the filtrate and ppt. the As by treatment with pure ZnS . Dissolve the ppt. in NaOH soln., make strongly acid with 3 N HCl and reprecip. with ZnS . Dissolve the ppt. in concd. HNO_3 , add 15 ml. of H_2SO_4 and 3 g. of KHSO_5 . Fume for 15 mins. Cool, add 0.5 g. of tartaric acid, make ammoniacal and then slightly acid with dil. H_2SO_4 . Titrate the trivalent As with I_2 in the presence of excess NaHCO_3 .

W. T. H.

Standard methods of analysis of brasses. A. E. LEIGHTON, *Australia Dept. of Defence Munitions Supply Board*, May 1926, 9 pp.—*Detn. of Sn.* If the brass contains more than 2% of Sn, det. this metal as in bronze. Otherwise take 5 g. of sample, decomp. with 50 ml. of 6 N HNO_3 and analyze as described for the detn. of Sn in bronze but using only 40 ml. of hot water for digesting the impure SnO_2 residue obtained by evapn. of the HNO_3 soln. *Detn. of Pb.*—Use the filtrate from the first pptn. of metastannic acid and proceed as described for the analysis of Al metal. This gives results sufficiently accurate for most purposes. If it is desired to det. traces of Pb with greater accuracy, treat 100 g. of brass with enough aqua regia to dissolve it, boil off excess Cl_2 , add 5 g. of Mohr's salt, add 5 ml. of concd. HNO_3 and boil 10–15 mins. Cool, add an excess of ammonia and filter. The $\text{Fe}(\text{OH})_3$ ppt. will occlude all of the Pb. Dissolve the ppt. in HCl , add "lead acid" and continue as in the detn. of Pb in Al metal. After weighing the PbSO_4 ppt. wash it with hot NH_4OAc soln., heat and weigh the insol. residue. *Detn. of Cu.* For the volumetric detn. of Cu, take $\frac{1}{10}$ of the filtrate from the PbSO_4 pptn., or dissolve 0.5 g. of brass in 10 ml. of aqua regia. In either case, boil off most of the excess acid, cool and add Na_2CO_3 until a slight blue ppt. is obtained. Dissolve the ppt. in an excess of AcOH , filtering if a scum of basic ferric acetate forms. Add 2.5 g. of KI and titrate with thiosulfate. For the electrolytic detn. take $\frac{1}{10}$ of the filtrate from the PbSO_4 or dissolve 1 g. of brass in 30 ml. of 7.5 N HNO_3 and boil to expel brown fumes. Dil. to 150 ml. and neutralize with NH_4OH . Add 1 ml. of concd. H_2SO_4 and heat to 40° . Electrolyze this soln. at 3 amps. for 40 min., adding 0.5 g. of urea after electrolyzing 15 min. *Detn. of Fe.*—To the remainder of the filtrate from the Pb detn., add 5 ml. of HNO_3 , boil, add 5 g. of NH_4Cl and ppt. with NH_4OH . Dissolve the first $\text{Fe}(\text{OH})_3$ ppt. in HCl and repeat the pptn., finally weighing as Fe_2O_3 . Usually the Al content is negligible. *Detn. of Fe and Al.*—Instead of igniting the Fe ppt., dissolve it in HCl , carry out the NaOH method of sepg. Fe and Al, finally pptg. each constituent as hydroxide with NH_4OH . *Detn. of Ni.*—Brass does not usually contain Ni. If present, take 1 g. of sample and remove Cu by electrolysis as described for the detn. of Cu. To the electrolyzed soln. add 0.5 g. of tartaric acid and det. the Ni by the conventional dimethylglyoxime method. *Detn. of Zn.*—In ordinary routine work, find Zn by difference. To det. Zn, use the soln. which has been electrolyzed for Cu or dissolve 1 g. of brass in 20 ml. of 6 N H_2SO_4 and take to fumes. Dil. to 150 ml., filter off any insol. Pb or Sn compd. and ppt. Cu by H_2S . Filter, wash and boil off H_2S from the filtrate. To the soln. obtained in either way, add 10 ml. of concd.

HNO_3 , boil a few min., cool, add 30 ml. of indicator soln. (450 g. $\text{KHC}_2\text{H}_3\text{O}_6$, 45 ml. of 10% FeCl_3 soln. and 2.5 l. of water), neutralize with ammonia and add 5 ml. in excess (omit the excess NH_4OH if less than 1% of Zn is present). Titrate at 80° with standard ferrocyanide soln., using glacial AcOH as outside indicator on a waxed plate. The end point is reached when a drop of the assay gives a light blue coloration with AcOH .

Detn. of Mn.—Dissolve 1 g. of brass in 20 ml. of 7.5 N HNO_3 , evap. to dryness, add 100 ml. of hot water and boil for 5 mins. Allow to stand 30 mins. in a warm place, filter, evap. to 30 ml., add 5 ml. of concd. H_2SO_4 and evap. to 20 ml. Then add AgNO_3 and $(\text{NH}_4)_2\text{S}_2\text{O}_8$ and carry out the persulfate detn. in the usual way, ending with the arsenite titration of MnO_4^- .

Detn. of P.—Dissolve 3 g. in 30 ml. of aqua regia, digest short of boiling for 10 min., add 15 ml. of water and digest another 15 min. Cool, add NH_4OH and carry out the Handy method as in the analysis of steel with acid molybdate soln., finally titrating the phosphomolybdate ppt. alkalimetrically.

Detn. of As.—A modified Gutzet procedure is described with considerable detail as well as a complicated evolution method which involves double pptn. of basic ferric salt, which adsorbs AsO_4^{---} anion, soln. of the final ppt. in HCl , evolution of AsCl_3 by distn. in the presence of Cu_2Cl_2 , KBr , FeCl_3 and concd. HCl and iodometric titration of the distillate in NaHCO_3 soln.

Detn. of Bi.—Dissolve 20 g. of brass in a small quantity of 7.5 N HNO_3 , nearly neutralize with Na_2CO_3 and add 1.5–2 g. of NaHCO_3 . Boil, allow to settle and filter. Dissolve the ppt. back into the original beaker, using 9 N H_2SO_4 as solvent. Add a slight excess of KI and sufficient H_2SO_4 to turn the soln. a pale brown and 1 drop in excess. Dil. to 500 ml., mix and take 50 ml. for the colorimetric test. In a 100 ml. Nessler tube, add 10 ml. of 9 N H_2SO_4 , sufficient H_2SO_4 to reduce all free I_2 and 1 drop in excess. Add a small crystal of KI to a second Nessler tube, dissolve in water and treat with H_2SO_4 and H_2SO_5 as just described. Transfer the 2 tubes to a colorimeter and match colors, adding standard $\text{Bi}(\text{NO}_3)_3$ soln. to the second tube till a match is obtained.

W. T. H.

Standard methods of analysis of bronzes. A. E. LEIGHTON. *Australia Dept. of Defence Munitions Supply Board*, May 1926, 8 pp.—*Procedure "A" for Pb, Sn and Cu.*—Dissolve 1 g. of bronze (or 0.5 g. if more than 10% of Sn is present) in 60 ml. of 9 N H_2SO_4 and 5 ml. of concd. HNO_3 . If the soln. is clear, add 3 ml. more of HNO_3 , dil. to 200 and electrolyze for Cu as in the analysis of brass. If the soln. is not clear, a gelatinous residue indicates P or As and a white ppt. indicates Pb in the alloy. Metastannic acid should not be formed; if it does, start again with a smaller wt. of sample. To the soln. contg. the ppt. add 20 ml. of dil. H_2SO_4 and take to fumes. Cool to room temp. and add quickly 150 ml. of cold water while stirring to prevent overheating. Cool in running water and filter off and weigh any PbSO_4 after the usual treatment. Electrolyze the filtrate from the PbSO_4 pptn. Then pass H_2S through the soln. to ppt. Sn, filter, wash with dil. NH_4NO_3 , ignite and weigh as SnO_2 .

Procedure "B" for Sn, Pb and Cu.—Treat 1 g. of bronze with 10 ml. of concd. HNO_3 , evap. to a paste and take up in 75 cc. of water. Filter and det. Sn iodometrically as described for the analysis of Al metal. In the filtrate, det. Pb as described for the analysis of Al metal. Det. Cu iodometrically in a fresh sample as explained for the analysis of brass.

Detn. of Fe, Al and Zn.—Proceed as described for the analysis of brass.

Detn. of Ni.—Digest 2 g. of sample with 30 ml. of 7.5 N HNO_3 , evap. almost to dryness and take up with 100 ml. of hot water. Remove SnO_2 and electrolyze the HNO_3 soln. After this, add tartaric acid and carry out the dimethylglyoxime method in the usual manner.

Detn. of Mn.—Proceed as with brass.

Detn. of P.—Use 3 g. if less than 0.15%, 2 g. if 0.16–0.4%, 1 g. if 0.41–0.80% and 0.5 g. if more than 0.81% of P is present. Decompose with a mixt. of 25 ml. HNO_3 and 10 ml. HCl , digest 10 mins. just below the boiling temp. and continue as described in the analysis of brass.

— W. T. H.

Standard methods of analysis of aluminum alloys. A. E. LEIGHTON. *Australia Dept. of Defence Munitions Supply Board*, May 1926, 7 pp.

Detn. of Si. Treat 1 g. of sample with 35 ml. of an acid mixt. (obtained by mixing 1.2 l. of 2.5 N H_2SO_4 , 0.6 l. of 10.5 N HCl and 0.2 l. of 15.5 N HNO_3). Heat until the sample is well decompd., the excess HCl and HNO_3 are removed and copious H_2SO_4 fumes are evolved. Cool, add 10 ml. of 2.5 N H_2SO_4 and 100 cc. of water. Boil, filter, wash and continue in the usual manner.

Detn. of Cu, Pb, Fe, Mg and Ni. Treat 5 g. of metal with 125 ml. of 25% NaOH soln. When all the Al has dissolved, add 100 ml. of water, filter and wash with hot 2% NaOH soln. Treat the filtrate with NaOH ; if no ppt. is formed, Zn is absent. If Zn is present, det. it in a fresh sample of metal as described below. Wash off the residue undissolved by NaOH back into the original porcelain dish and pour 20 ml. of hot, 7.5 N HNO_3 through the filter into the dish. Boil until all the residue has dissolved, dil. with 50 cc. of hot water, filter through the original filter and wash

the filter well with hot water. Retain the filtrate for the detn. of Cu, Pb, Mg and Ni. Reject the residue because some of the Sn is dissolved by the original treatment with NaOH. *Detn. of Pb.*—To the last-mentioned filtrate, add 120 ml. of "lead acid" (mix 300 ml. of concd. H_2SO_4 with 1.8 l. of water and pour into it a hot soln. of 1 g. $\text{Pb}(\text{OAc})_2$ in 300 ml. of water). Evap. to copious fumes and det. the Pb as PbSO_4 in the usual way, washing the ppt. with 50% alc. and heating the Gooch crucible to redness inside another porcelain crucible. *Detn. of Cu.*—Neutralize the filtrate from the PbSO_4 with NH_4OH , add 0.5 ml. of HNO_3 and det. the Cu by electrolysis. *Detn. of Fe.*—To the electrolyzed soln., add 5 ml. of concd. HNO_3 and boil to make sure that the Fe is all oxidized. Ppt. as $\text{Fe}(\text{OH})_3$, twice and ignite to Fe_2O_3 . *Detn. of Ni.*—Take one-half of the last filtrate and det. the Ni with dimethylglyoxime, in a soln. which is at first barely acid with HCl and is finally made slightly ammoniacal. *Detn. of Mg.*—In the other half of the filtrate from the Fe detn. ppt. Zn and Ni with H_2S , filter, make the filtrate acid, boil off H_2S , add $(\text{NH}_4)_2\text{S}_2\text{O}_8$ to oxidize any pptd. S., add 1 g. of tartaric acid and 30 ml. of satd. microcosmic salt soln. to ppt. the MgNH_4PO_4 . Ignite and weigh as $\text{Mg}_2\text{P}_2\text{O}_7$. *Detn. of Mn.*—Use 0.1 g. of sample if 1.5% of Mn is present, or corresponding wts. as the Mn varies. The method described is the well-known persulfate method as used in the rapid detn. of Mn in steel. The sample is dissolved in 25 ml. of 18 N H_2SO_4 and a little HNO_3 added to oxidize the Fe before adding the AgNO_3 and $(\text{NH}_4)_2\text{S}_2\text{O}_8$. *Detn. of Zn.*—Treat 1 g. of sample with 25 ml. of 6 N HCl and, when mostly dissolved, add 1 ml. of concd. HNO_3 . Boil to expel nitrous oxides, dil. to 200 ml., sat. with H_2S , filter and wash with 3.6 N H_2SO_4 which has been satd. with H_2S . Boil off H_2S from the filtrate, neutralize with NH_4OH using methyl orange as indicator, add 25 ml. of a soln. prepared by mixing 400 ml. of formic acid with 60 ml. of concd. NH_4OH and dilg. to 2 l., heat to boiling and introduce H_2S , until the soln. is cool. Filter and wash with 2.5% HCO_2H satd. with H_2S . Dissolve the impure ZnS ppt. in hot N HCl , add 1 g. of citric acid, neutralize with NH_4OH , add 20 ml. of the formic acid mixt. and again ppt. with H_2S as before. Dissolve the well-washed ppt. in dil. HCl , transfer the soln. to a Pt dish or crucible, add H_2SO_4 and evap. to fumes. Add HNO_3 as necessary to destroy org. matter, evap. to dryness and weigh as ZnSO_4 . *Detn. of Sn.*—If less than 2% of Sn is present, treat 2 g. of metal with 90 ml. of 5 N HNO_3 , evap. to 10 ml., add 40 ml. of hot water, keep warm for 15 min., filter, wash with 2% HNO_3 , ignite and weigh as impure SnO_2 . Fuse with Na_2CO_3 and S in a covered porcelain crucible, leach with water, adding $\text{Na}_2\text{S}_2\text{O}_8$ soln. until the soln. is a pale yellow, filter, wash with dil. Na_2S soln., then with dil. H_2S soln., ignite and weigh. Deduct this wt. from that of the impure SnO_2 . If more than 2% of Sn is present it is better to det. Sn iodometrically. Treat 1 g. of metal with 10 ml. of concd. HNO_3 , evap. to a paste, add 75 ml. of hot water and boil a few min. Filter while hot through asbestos, keeping back as much as possible of the SnO_2 ppt. and wash with hot, very dil. HNO_3 . Transfer the asbestos and ppt. back to the original 250 ml. Erlenmeyer flask in which the sample was dissolved, add concd. H_2SO_4 equal in vol. to the water used in transferring the ppt. (about 20 ml.) and boil vigorously for 3 min. Add 50 ml. of concd. HCl and boil 2 min. longer to dissolve all of the SnO_2 . Add 1 g. of powdered Sb and boil 3 min., remove from the heat, insert a rubber stopper and cool so that NaHCO_3 is sucked into the flask while cooling. Finally unstopper, add a small piece of marble and titrate with 0.05 N I_2 soln.

W. T. H.

Standard methods of analysis of copper-nickel and copper-nickel-zinc alloys.

A. E. LEIGHTON. *Australia Dept. of Defence Munitions Supply Board*, May 1926, 12 pp. — *Detn. of Cu.*—Electrolysis of the HNO_3 soln. is described. The use of the iodide method is optional. *Detn. of Ni.*—Take the filtrate from the Cu detn., add 4 ml. of H_2SO_4 and evap. to fumes. Cool, add 75 ml. of water and sat. with H_2S . Filter, boil off H_2S and electrolyze the soln. after adding NH_4OH and $(\text{NH}_4)_2\text{SO}_4$. If Co is present, dissolve the ppt. and det. Co by the nitroso- β -naphthol method. It is also permissible to det. the Ni by the dimethylglyoxime method without electrolyzing and then in the filtrate the Co can be detd. *Detn. of Si.*—Treat 20 g. of sample with HNO_3 , evap. with HCl and continue in the usual way. *Detn. of S.*—Take the filtrate from the Si detn. and ppt. as BaSO_4 . Care must be taken to prevent outside contamination and Fe should be removed first if it is present. *Detn. of Zn.*—After the removal of Cu, Ni and Co as described above, evap. with HNO_3 and H_2SO_4 and det. the Zn by the ferrocyanide titration, using the indicator described for the analysis of brass. *Detn. of Fe.*—Dissolve 5 g. in 7.5 N HNO_3 , avoiding an excess. Add Br_2 aq. and NH_4OH in slight excess. Heat to boiling and allow to stand for several hrs. Filter, dissolve in hot, dil. HCl , make neutral with Na carbonate and add 3 ml. of 33% AcOH . Boil, filter, ignite and weigh as Fe_2O_3 . *Detn. of Mn.*—Carry out the persulfate method as

in the analysis of brass. *Detn. of graphitic C.*—Treat 10 g. of sample with 300 ml. of 4 $NHNO_3$, filter, burn the residue in a combustion tube, running a blank. *Detn. of As.*—A modified Gutzeit procedure is recommended but an evolution method is permitted as in the analysis of brass. W. T. H.

Electrometric determination of chromic acid in the presence of vanadic acid with the aid of induction and catalysis. E. ZINTL AND P. ZAIMIS. Univ. Freiburg. *Z. Elektrochem.* 34, 714-5(1928).—Lang and Zwerina (*C. A.* 22, 3600) criticised a former paper of Z. and Z. (*C. A.* 22, 556) but some of the grounds for the criticism do not appear to be well-founded. W. T. H.

Acidimetric determination of phosphate. M. HEGEDÜS. *Z. anal. Chem.* 75, 111-20(1928).—If a soln. of a primary phosphate is treated with $AgOAc$, a ppt. of Ag_3PO_4 is formed and after filtering off the ppt. and removing the excess Ag as $AgCl$, the PO_4^{---} can be detd. indirectly by titrating with $NaOH$, phenolphthalein being used as indicator. $H_2PO_4^- + 3Ag^+ \rightarrow Ag_3PO_4 + 2H^+$. Dissolve the phosphate (0.05-0.1 g. of P_2O_5) in a little dil. HNO_3 and boil to decompose any carbonate present, and cool. Dissolve, in the same vol. of water, 0.1 g. of pure KH_2PO_4 . To both solns. add a drop of methyl orange soln. and add 0.1 N $NaOH$ soln. free from carbonate till the color of the first soln. is the same as that of the second. Then, to each soln. add at least 10 cc. of satd. $AgOAc$ soln. for each 0.01 g. of P_2O_5 present. Allow to stand 15 min., filter and wash with cold, CO_2 -free water. Add 2-3 g. of $NaCl$, and 0.5 cc. of phenolphthalein soln.; titrate with 0.1 N $NaOH$, free from carbonate. The method succeeds in the presence of carbonate, chloride, nitrate and sulfate (when not more than 10 times as much of the last-mentioned is present) but is inaccurate in the presence of NH_4 salts, alk. earths and earths. W. T. H.

Detection of pentathionic acid in the presence of sulfurous acid. ADOLF CZERNOTZKY. Techn. Hochschule Brünn. *Z. anorg. allgem. Chem.* 175, 402-4(1928).—The detection of $S_5O_6^{---}$ in aq. soln. is often based upon the fact that it decomposes into $S_4O_6^{---}$ and S in the presence of OH^- . There is, however, no deposition of S when SO_3^{---} is also present. Similarly the test with ammoniacal Ag soln. fails in the presence of sulfite. If, however, $HCHO$ is first added to the soln., the sulfite ion reacts quickly to form $CH_3O.HSO_3^-$ and then the S deposition characteristic of $S_5O_6^{---}$ in alk. soln. can be obtained. About 1 millimol. of $S_5O_6^{---}$ in the presence of 25 times as much SO_3^{---} can be detected in this way. W. T. H.

Notes on the determination of polythionates. E. H. RIESENFELD AND G. SYDOW. *Z. anorg. allgem. Chem.* 175, 74-9(1928).—If 1 g. of trithionate is treated with 30 cc. of 10% $CuCl_2$, 100 cc. of 10% $BaCl_2$ and 20 cc. of 6 N HCl and the mixt. is boiled 1 hr., all of the S will be obtained as $BaSO_4$. This test succeeds in the presence of tetrathionate, thiosulfate and sulfite. The reaction is noteworthy inasmuch as CuS and SO_4^{---} are said to be formed in the absence of Ba^{++} . When Ba is present, the reaction can be represented by the equation: $S_3O_6^{---} + 8Cu^{++} + 6H_2O \rightarrow 3SO_4^{---} + 8Cu^+ + 12H^+$. The di-, tri- and tetrathionates can be oxidized to sulfate by the action of a stronger oxidizer such as I_2 . To make the reaction go quantitatively it is best to heat in a sealed tube at 100° for an hr. Then the excess I_2 can be titrated with thiosulfate after adding acid. W. T. H.

Quantitative separations and determinations by volatilization with hydrogen chloride gas. VII. Separation and determination of the constituents of tungstates. GERHART JANDER AND DIETRICH MOJERT. Univ. Göttingen. *Z. anorg. allgem. Chem.* 175, 270-6(1928); cf. *C. A.* 22, 4080.—By heating $Na_2WO_4 \cdot 2H_2O$, $BaWO_4$ and $Na_{10}W_{12}O_{41} \cdot 28H_2O$ to about 600° in a stream of HCl contg. a little $CHCl_3$, all of the W can be easily volatilized and condensed in dil. HCl . The weight of the residual chloride corresponds to that of the Na or Ba present and in the distillate the W can be detd. by evapg. with HNO_3 , dissolving the residue in NH_4OH , filtering and pptg. with $HgNO_3$. W. T. H.

Use of liquid amalgams in volumetric analysis. XI. Determination of phosphoric acid using zinc or cadmium amalgam. KIN'CHI SOMEYA. Tôhoku Imp. Univ. *Z. anorg. allgem. Chem.* 175, 347-56(1928).—The method recommended is the same as the Blair method for the detn. of P in steel, except that the yellow phosphomolybdate ppt. is dissolved in dil. NH_4OH , the soln. is concd. into a small vol. and reduced by treatment with 200-300 g. of liquid amalgam, 5-10 cc. of 18 N H_2SO_4 and 50 cc. of water. The reduction of MoO_4^{---} to Mo^{+++} is complete in an atm. of CO_2 and the Mo^{+++} is oxidized back to MoO_4^{---} by $KMnO_4$. Cf. *C. A.* 22, 2122. W. T. H.

Standard methods of examination of mineral jelly. A. E. LEIGHTON. Australia Dept. of Defence Munitions Supply Board, May 1926, 8 pp.—Acidity or alkalinity.—Treat 10 g. of jelly with 100 ml. of hot water and shake until the jelly solidifies. Test

the aq. ext. with methyl orange. If alk., titrate with 0.01 *N* HCl, running a blank test at the same time and reporting the alk. in terms of Na_2CO_3 . Test a similar aq. ext. in the same way with phenolphthalein. If it is not alk. to this indicator, titrate with 0.01 *N* $\text{Ba}(\text{OH})_2$ soln., expressing the results in terms of H_2SO_4 . **Acidity.**—Melt about 11 g. of the jelly and, while still liquid, treat with 100 ml. of ether. Add 2 ml. of phenolphthalein indicator soln. and 100 ml. of abs. alc. Allow to stand overnight and titrate 101 ml. with 0.05 *N* KOH. Run a blank at the same time. **Saponifiable matter.**—Boil 10 g. of sample with 25 cc. of benzene and 25 ml. of 0.1 *N* KOH in abs. alc. under a reflux condenser. Cool, add 50 ml. of abs. alc. and titrate with 0.1 *N* HCl using phenolphthalein. **Suspended matter and solid mineral matter.**—To 10 g. of molten jelly, add 100 ml. of ether and shake in a 250 ml. bottle till the jelly has all dissolved. **Filter.**—If the sample is for the manuf. of cordite, wash the paper with ether, ignite and weigh. **Mineral matter.**—Carefully ignite 20 g. of sample, weigh the residue, calc. the % of ash and exam. it for grit on a glass slide with a glass spatula or rod. **Volatile matter.**—According to the specifications under which the jelly is purchased, det. the loss in wt. after heating 12 hrs. on the boiling water bath, by heating to const. wt. on the water bath, or by heating 6 hrs. at 100°, finally cooling in a desiccator in all cases. **Water.**—Soak sheets of filter paper in 2% $\text{K}_3\text{Fe}(\text{CN})_6$ soln., dry thoroughly and keep in a desiccator. When required for use, dust finely powdered copperas over the surface of the paper and shake off the excess. Place 50 g. of sample in a tall 100 ml. beaker, cover with a freshly dusted filter paper and heat on a hot plate to about 110°. The development of a blue color indicates the presence of moisture in the sample. **Melting point.**—Dip the standard thermometer, reading to tenths of a degree, into the melted fat so that on withdrawal a drop of fat is left hanging to the bulb. Place the thermometer in a test tube and clamp in an upright position. Place the test tube in a beaker of water and allow to stand 24 hrs. Then slowly raise the temp. of the water and note the temp. at which the drop falls off. The reading of the thermometer should be corrected for stem exposure. **Dropping point.**—Directions are given for using the Ubbelohde app. **Reactivity test.**—From a self-filling buret take 15 ml. of CCl_4 soln. contg. 0.16 g. of Br, add 20 ml. of 10% KI soln. and 40 ml. of water. Shake well, allow to stand 1 min. and titrate with 0.1 *N* thiosulfate soln., adding starch indicator toward the last. Melt 1 g. of jelly on the water bath and add 10 ml. of CCl_4 , stirring and heating till the jelly is all dissolved. Transfer to a tap tube to which has been added 1 ml. of CCl_4 to fill the capillary at the bottom of the tube. Rinse the contents of the beaker contg. the jelly into the tap tube using small quantities of CCl_4 to effect the transfer. The final vol. should be about 50 ml. Heat the contents of the tap tube for 15 mins. in a water bath at 20°, remove the tube from the bath and add Br-CCl_4 as in the preliminary expt. Shake gently, replace stopper in the tube, and in the covered water bath allow the tube to remain 1 hr. in the dark. Add 20 ml. of KI soln. and 40 ml. of water. After 1 min. titrate with thiosulfate. Express the reactivity in terms of mg. of Br per g. of jelly. **Flash point.**—The Pensky-Martens app. should be used as recommended by the Institution of Petroleum Technologists. **Sp. gr. at 100° F.**—Weigh a dry bob in air, then in water, then in air with a mineral jelly coating and then in water again with this coating. **Detn. of Pb.**—Ignite 20 g. of jelly and, if the ash is greater than the permitted Pb content, digest it with aqua regia, add HCl, evap., dil. with hot water, neutralize with NH_4OH , make acid with AcOH , dil. to 150 ml. and add some K_2CrO_4 soln. Filter and wash with hot water. Dissolve the Pb-CrO_4 ppt. in hot, dil. NaOH soln., dil. to 100 ml., neutralize with 6 *N* H_2SO_4 and add 25 ml. in excess. Add 0.5 g. of KI, allow to stand 15 min. in the dark and titrate with $\text{Na}_2\text{S}_2\text{O}_3$. W. T. H.

Determination of iron carbonyl. R. H. GRIFFITH AND G. C. HOLLIDAY. *J. Soc. Chem. Ind.* 47, 311–12T (1928).—In the manuf. of methanol from CO and H_2 in the presence of Fe, there is the possibility of some Fe carbonyl being formed, the ultimate decompn. of which may affect the catalyst. It was, therefore, desirable to develop a method for the detn. of Fe carbonyl in gases. By washing the gas with dil. H_2SO_4 , the carbonyl is decompd. and by evapn. of the acid to dryness a sulfate of Fe is obtained. By dissolving the residue in water, this Fe can be detd. by a color density method based on the Prussian blue reaction. The method is so sensitive that it will serve to detect very small quantities of carbonyl and will show the presence of Fe in most reagents. W. T. H.

Determining total solids of certain liquids. H. H. KRAUSE. *Chemist-Analyst* 17, No. 4, 14 (1928).—The method described is that used in a rubber lab. for the detn. of total solids in latex. W. T. H.

The Jaffe picric acid reaction. W. WEISE AND C. TROPP. *Inst. Schiff. u. Tropen-*

krankheiten, Hamburg. *Z. physiol. Chem.* 178, 125-38(1928).—The Jaffe picric acid reaction for creatinine (red color in alk. soln.) is the special case of a general reaction for substances with active methylene or methine groups. It differs from the Braun reaction for glucose and other reducing substances which partially reduce picric to picramic acid in that heat is not required to bring about the color change. To perform the reaction under standard conditions, prep. the reagent by adding 5 cc. of 10% NaOH to 10 cc. of a satd. aq. picric acid soln. and dilg. to 25 cc. To 5 cc. of this reagent add 20-50 mg. of the substance to be tested, shake the mixt. and compare the color with that of the reagent itself. If a distinct red color develops in 3 min. the reaction is considered pos. When the reaction is neg., on account of insoly. of the substance, add an equal vol. of EtOH and observe the color again after 3 min. Some 75 substances were subjected to this color test. The following typical examples illustrate the structures required for a positive reaction:

Positive reaction	Negative reaction
Acetaldehyde	Benzaldehyde
Acetone	Benzophenone
Diacetyl	Benzoin
Cyclohexanone	<i>d</i> -Camphor
Phenylacetamide	Acetamide
Malonamide	Oxamide
Hydantoin	5,5-Ethylphenylhydantoin
Barbituric acid	Parabanic acid
Ethyl phenylacetate	Ethyl acetate
Ethyl malonate	Ethyl oxalate
<i>p</i> -Allylanisole	Styrene
Indene	Diphenylmethane
Benzyl cyanide	Acetonitrile
Nitromethane	
Diazomethane	

The activation of methylene or methine by other groups occurs in the order: diazo, nitro > carbonyl > cyano > vinylene > carbaminyll > carbethoxyl. A. W. DOX

Some recent determinations of aspartic and glutamic acids in various proteins. D. BREESE JONES AND OTTO MOELLER. Bureau of Chem. and Soils, Wash. *J. Biol. Chem.* 79, 429-41(1928).—The aspartic and glutamic acid contents of a no. of typical proteins were detd. and compared with the values obtained by the older ester method. The older results are too low in almost all cases recorded in the literature, particularly those recorded for aspartic acid.

ARTHUR GROLLMAN

Micro-identification of isomers and homologs in their mixture. I. Three isomeric xylenes. MASAO MIGITA. Tokyo Imperial Univ. *Bull. Chem. Soc. Japan* 3, 191-9(1928).—*m*-Xylene and *p*-xylene, even in minute quantity, are successfully identified as their trinitro derivs., by their color reaction toward alkali in alc. or Me₂CO soln., or by the optical properties of their crystals. *o*-Xylene is identified microscopically as Na sulfonate, but in a mixt. very poor in *o*-xylene, a result of high sensitivity cannot be expected of this method. The technical method of sepg. *p*-xylene from its isomers by means of concd. H₂SO₄ is of little value.

A. L. HENNE

Lehmann's method of determining aniline. A. V. PAMFILOV AND V. F. KISSELEVA. *Z. anal. Chem.* 75, 87-92(1928).—L.'s method consists in absorbing aniline from air by passing it through 10% H₂SO₄, subsequently neutralizing the greater part of the excess acid and titrating with standard NaBrO soln. Apparently L., in his study of the method, added an excess of NaBrO and detd. the excess by adding KI and titrating with Na₂S₂O₃. It is here shown that direct titration of the aniline with Br in KBr soln. or with KBrO₃ soln. using indigocarmine as indicator is much more convenient. Or, better still, the end point can be detd. potentiometrically. L.'s method in its original form can be used for the detn. of small quantities of aniline if 1-2 g. of KBr is added together with the NaBrO and the soln. is allowed to stand a little while after the addition of iodide. The analysis should also be carried out in a flask with glass stopper and preferably a liquid seal.

W. T. H.

Rapid volumetric determination of glucose. CHESTER A. AMICK. *Chemist-Analyst* 17, No. 4, 10-11(1928).—Dil. 30 cc. of 2 N CuSO₄ soln. with 50 cc. of water and heat to boiling in a 250-cc. Erlenmeyer flask. Add 10 cc. of the glucose soln. and 10 cc. of 6 N NaOH soln. (free from carbonate). Heat on the water bath for 15 min., then cool in ice water to room temp. Add to the cooled soln. 50 cc. of phosphomolybdate soln. prepd. by adding dissolving 100 g. of Na₂MoO₄ in 500 cc. of water and adding

75 cc. of 85% H_3PO_4 , 275 cc. of concd. H_2SO_4 , and enough water to make 1750 cc. The clear phosphomolybdate soln. is reduced to green Mo^{+++} by the glucose and the Mo^{+++} which can be titrated back to MoO_4^{--} by KMnO_4 standardized against pure glucose which has been subjected to the above treatment. W. T. H.

Detection and estimation of sucrose by the ammonium molybdate method. NORRIS W. MATTHEWS. *Chemist-Analyst* 17, No. 4, 8(1928).—See C. A. 22, 3312.

The determination of sucrose by the use of alkaline iodine solution. G. BORRIES. German Board of Health Lab., Berlin. *Z. Untersuch. Lebensm.* 5, 405-15(1928).—By KI , soln. in the presence of OH^- glucose and other aldoses are oxidized to glycolic acid. By back-titration of the unused I , the aldoses can be detd. Methods of estn. of sucrose after inversion and also for the detn. of sucrose in the presence of invert sugar are given. Numerous data show a remarkable concordance of the results. C. R. FELLERS

Detection of traces of lead in organic substances. RAGNAR BERG. Stadtkrankenhaus Friedrichstadt, Dresden. *Biochem. Z.* 198, 420-3(1928).—After digestion with H_2SO_4 as in the Kjeldahl method, transfer the soln. to a Pt dish, evap. off the excess acid, add 4% HNO_3 and electrolyze in a small Pt crucible. Dissolve the deposited PbO_2 in 4-5 cc. of 20% HCl , rinsing off the cathode with 3 cc. portions of 4% NaOAc . Conc. the soln. and test for Pb by Fairhall's method. S. MORGULIS

Reactions of dyestuffs with nitrous acid. J. V. DUBSKÝ AND A. OKÁC. *Z. anal. Chem.* 75, 92-111(1928); cf. C. A. 22, 1929.—Studies with over 100 dyestuffs from 13 different mfrs. show that the sp. diazotization and coupling reaction can be used for the identification of HNO_2 with many dyes which are capable of undergoing further diazotization. These dyes serve to detect HNO_2 in concs. of 10^{-4} - 10^{-7} . On diazotizing the color, except in the case of the safranines, becomes lighter but on coupling a darker shade develops. In the coupling reaction, the α -compds. with free p -positions are more favorable from the analytical point of view than the p -compds. with free o -positions because the former react more rapidly and give much deeper shades. W. T. H.

Standard methods of analysis of flux soldering (commercial oleic acid). A. E. LEIGHTON. Australia Dept. of Defence Munitions Supply Board, May 1926, 1 p.—*Detn. of free fatty acids*.—Dissolve 5 g. in 50 ml. of alc., add a few drops of phenolphthalein and titrate hot with N NaOH . *Detn. of mineral acidity*.—Shake 20 g. of sample with 100 ml. of water at 60-70°. Sep. the 2 layers and shake again with a further 50 ml. of water. Titrate the combined aq. exts. with 0.1 N NaOH , using methyl orange as indicator. *Detn. of water-soluble organic acidity*.—Prep. an aq. ext. as above, filter and titrate with phenolphthalein as indicator. From the vol. used, deduct a vol. that corresponds to the mineral acid content. W. T. H.

Experiments on Fe (KNOWLTON) 9.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

Eleventh list of new mineral names. L. J. SPENCER. *Mineralog. Mag.* 21, 556-82(1928); cf. C. A. 20, 161.—The first list of new mineral names by S. appeared in 1897 and subsequent lists about every 3 years. In the first 10 lists, 1500 names are included, in the 11th, 190. W. F. HUNT

Determination of the optic angle and crystal forms from observations by the Becke method in thin sections. HARVEY COLLINGRIDGE. *Mineralog. Mag.* 21, 552-5(1928).—Observations on different sections showing the trace of the optic axial plane, the position of one optic axis, the extinction direction, and the traces of cleavage are brought together in one stereographic diagram. From the data thus collected the crystal is reconstructed. Olivine is used as an illustration. W. F. HUNT

Studies on the solubilities of carbonate minerals and carbonates in carbonic acid solutions. RAGNAR LYDÉN. *Finska Kemistsamfundets Medd.* 34, 72-9(1925).—Solubilities were detd. by passing CO_2 through H_2O in contact with the solid for 24-36 hrs. Five hundred cc. of the clear soln. were then evapd. on a tared watch glass and the residue was analyzed. Dolomite (Soanlaks Kintsinniemi) with the compn. insol. 0.66, Fe_2O_3 + Al_2O_3 0.18, MnO 0.45, CaO 30.83, MgO 20.68, and CO_2 47.34% gave 0.362 g. dry matter per 500 cc. soln. The ratio $\text{CaCO}_3:\text{MgCO}_3$ in the original was 1:0.7859.

and in the soln. 1:0.7696. Siderite (unknown origin) of the compn. insol. 3.74, FeO 46.40, MnO 7.94, CaO 1.98, MgO 2.83, and CO₂ 87.54% gave 0.0632 g. per 500 cc. The ratio FeCO₃:MnCO₃:CaCO₃:MgCO₃ in the original was 1:0.172:0.047:0.079 and in the soln. 1:0.148:0.239:0.172. Magnesite (Baumgarten, Silesia) of the compn. insol. 3.26, CaO 15.92, MgO 31.11, and CO₂ + H₂O 50.57% was mixed with 52% of its wt. of calcite (unknown origin) of the compn. insol. 1.28, Fe₂O₃ + Al₂O₃ 0.46, CaO 54.06, MgO 1.02, and CO₂ 43.90%. The soln. contained 0.4872 g. dry matter per 500 cc. The ratio CaCO₃:MgCO₃ in the original was 1:0.8416 and in the soln. 1:0.0396. Rhodochrosite (unknown origin) of the compn. MnO 61.57 and CO₂ 38.19% gave 0.0127 g. Mn₂O₄ per 500 cc. soln., a value 6 times smaller than usually given in the literature. Magnesite (Snarum, Norway) of the compn. insol. 4.51, Fe₂O₃ 1.63, CaO 4.78, MgO 41.35, and CO₂ 48.03 gave 0.0338 g. per 500 cc. The ratio CaCO₃:MgCO₃ in the original was 1:10.14 and in the soln. 1:4.03. A mixt. of 3 g. dolomite and 1 g. basic MgCO₃ (Kahlbaum) gave 0.3609 g. dry matter per 500 cc. HANS C. DUUS

The optical orientation of labradorite from County Down, Ireland, determined by the Fedorov method. W. CAMPBELL SMITH. *Mineralog. Mag.* 21, 543-51 (1928).—Labradorite of exceptional purity occurring in basaltic dikes was studied. Chem. analysis and *ns.* had previously been detd. It is + with 2 V = 82°, and the max. extinction angle in zone perpendicular to (010) averaged 36° for 5 crystals, corresponding to 61½% An. Of the 15 crystals examd. one shows albite, Carlsbad and pericline twinning; 4 show albite and pericline; 4 albite-Carlsbad; and 6 albite alone.

W. F. HUNT

Genesis of Burman jadeite. A. LACROIX. *Compt. rend.* 187, 489-93 (1928).—A study of the genesis of jadeite, or more properly *jadeitite*, was made from material collected among the lapidaries and jade merchants of China and Upper Burma. Ten analyses are reported including albitite, albitic jadeitite, jadeitite (theoretical), jadeitite with nepheline, amphibolic jadeitite, amphibolite with tawmawite, lamellar szechenyite, acicular szechenyite and tawmawite. This series shows a general loss in SiO₂, Na₂O and K₂O, and a gain in Fe₂O₃, FeO, MgO, CaO and H₂O. The compn. of jadeitite (3rd in above list) is: SiO₂ 58.48, Al₂O₃ 23.57, Fe₂O₃ 1.68, MgO 1.33, CaO 1.62, Na₂O 10.33, K₂O 3.09, H₂O + 0.16, sum 100.26%. L. W. RIGGS

Moldavites or vltavines from Bohemia and Moravia. FRANTIŠEK HANUŠ. *Rozpravy České Akad. Class 2*, 37, No. 24, 83 pp. (1928); *Mineralog. Abstracts* 3, 537.—It is suggested that moldavites were derived from a single meteoric mass. The air pressure opposing a velocity of 1.5-2 km. per second would be sufficient to cause the sepn. of molten drops (m. 1300-1500°). Two unpublished analyses of moldavites are given.

J. F. SCHAIERER

Italian mines. CARLO PARNISARI. *Notiz. chim. ind.* 3, 275-7, 352-4 (1928); cf. *Notiz. chim. ind.* 3, 134 (1928).—An illustrated description of deposits of various minerals on the Island of Elba, in Tuscany, Sicily, Emilia and central and southern Italy.

C. C. DAVIS

Microscopic examination of the magnesite deposit of Kraubath in Steiermark. E. CLAR. *Z. prakt. Geol.* 36, 97-102 (1928).—A description of the crystn. of the magnesite and its assocd. minerals is given, with a discussion of genesis. The part played by colloidal solns. is noted.

W. H. NEWHOUSE

The gold occurrence of the Pitanguy district in eastern Minas Geraes, Brazil. T. KNECHT. *Z. prakt. Geol.* 36, 7-11 (1928).—The Au occurs in quartz veins in pre-Cambrian schists. Free Au in a finely divided state is found particularly in the oxidation zone with Fe oxides, while the unoxidized ore shows pyrite and arsenopyrite, with Au content.

W. H. NEWHOUSE

Bornite occurrence of Saint-Veran. C. E. WEGMANN. *Z. prakt. Geol.* 36, 19-28 (1928).—The ore masses occur at the contact of serpentine-gabbro masses and schists. Glaucophane is assocd. with the ore, which is composed of bornite, chalcocite and chalcopyrite, with hematite and magnetite also present.

W. H. NEWHOUSE

The zinc vein of Gidrevet, south of Batum, Caucasus. C. KUZNIAR. *Z. prakt. Geol.* 36, 65-7 (1928).—The minerals present are sphalerite, chalcopyrite, galena, and pyrite, with much quartz and some siderite. Adjacent andesite is impregnated by pyrite and strongly propylitized.

W. H. NEWHOUSE

The platinum deposits of the Republic of Colombia. G. J. KELLNER. *Z. prakt. Geol.* 36, 1-7 (1928).—The history and geography are described. These alluvial deposits show many of the common black sand minerals.

W. H. NEWHOUSE

Manitoba as a mining province. A. H. A. ROBINSON. *Can. Dept. Mines, Mines Branch No.* 687, 31-5 (1928).—An extensive plant is being constructed at Flin Flon for

the handling of low-grade Cu ores carrying small quantities of Au and Ag. If this is successful, other extensive deposits in Manitoba will be exploited. L. W. RIGGS

Quicksilver occurrences in Canada. V. L. EARDLEY-WILMOT. *Can. Dept. Mines, Mines Branch No. 687*, 53-7(1928).—The Kamloops Lake deposits of Hg in British Columbia are of too low grade to be profitably mined, the output shipped in 1926-1927 being only 6 flasks. Other occurrences are reported in B. C. and in Ont. but the production is as yet unimportant. Occurrences, metallurgy and uses of mercury. *Ibid* 58-63.—At present the world demand for Hg is steadily increasing, while several of the largest known deposits are approaching exhaustion. L. W. RIGGS

Sodium carbonate at Soap Lake, B. C. L. H. COLE. *Can. Dept. Mines, Mines Branch No. 687*, 25-7(1928).—Soap Lake is situated about 7 miles by pack trail to the south of Spence's Bridge on the Can. Pacific Railway and 2000 ft. above the railway. This lake is about 1 mile long and 1300 ft. wide in its widest part, but varies in size with the dryness of the season. When low, the shore is covered with white salts about 1 in. in depth. Analysis of the brine gave in p. p. m.: K none, Na 60018, Mg 169, Cl 2439, SO₄ 5900, HCO₃ 10697, CO₃ 67700, sum 146923. The profitable recovery of these salts depends on overcoming the difficulties in transportation to the railway. L. W. R.

Lithium minerals in southeastern Manitoba. HUGH S. SPENCE. *Can. Dept. Mines, Mines Branch No. 687*, 12-8(1928).—Li-bearing minerals were found in several localities 80 to 90 miles northeast of Winnipeg. A deposit near Pointe du Bois, in which the *spodumene* and *lepidolite* contained about 4% of Li₂O, has been slightly developed and shows favorable possibilities. In the samples tested, the *spodumene* appears to be sufficiently free from Fe and Mn to allow its use in glass manuf. The *lepidolite*, on the other hand, contained too much Fe and Mn for such use. Sufficient work has not been done to warrant an est. of the size of this deposit. In Township 16, R. 15, east of the Principal Meridian a deposit of *fuchsite* or Cr-mica was found. Analyses of 2 samples gave widely varying quantities of Cr, Si, Al and K. This mineral has been used for decorative purposes as stucco dash. L. W. RIGGS

Recent developments in the gypsum industry in British Columbia. L. H. COLE. *Can. Dept. Mines, Mines Branch No. 687*, 28-30(1928).—During 1926 the production of gypsum at Falkland and Mayook, B. C. was over 20,000 tons as compared with a yearly av. of about 150 tons for the preceding 5 years. The gypsum is used in making wall plaster, wall board and in the cement industry. An export market to Australia, New Zealand and Japan is rapidly developing. L. W. RIGGS

Proposed nomenclature and graphic representation of limestones according to their chemical composition. HERMANN HEINRICHS. *Glaserh. Ber.* 5, 597-601(1928).—H. divides limestones into 5 classes according to the CaCO₃, MgCO₃, and Al₂O₃ content. E. VALDEN

Limestones of Nova Scotia and New Brunswick. M. F. GOUDGE. *Can. Dept. Mines, Mines Branch No. 687*, 36-47(1928).—Analyses of samples collected in this survey will be given in a final report. The limestones of com. importance are of Precambrian or Carboniferous age. The George River Precambrian limestones of Nova Scotia are variable in their Ca-Mg ratio, the Mg ranging from 9 to 44%. The deposits of Carboniferous limestone in a dozen counties are briefly described. In 4 out of 5 analyses the Ca-Mg ratios were quite close. The Precambrian limestones of New Brunswick show varying Ca-Mg ratios similar to those of Nova Scotia. These limestones are burned for CaO and are ground for agricultural purposes. The Carboniferous limestones of New Brunswick are used only for agricultural purposes. **Limestones of the Gaspé Peninsula.** *Ibid* 48-9.—These are high Ca limestones and are used in agriculture and in the wood pulp industry. **Limestones of the Timiskaming District.** *Ibid* 50-2.—The Ordovician and Silurian limestones of this region are described. They are suitable for building stone and for the production of CaO. L. W. R.

An unusual fluor spar deposit. MARTIN SCHWERIN. *Eng. Mining J.* 126, 335-9 (1928).—A description of a bedded deposit of fluor spar at Elizabethtown, Ill. Fluor spar commonly occurs in vertical veins, and this horizontal deposit affords an unusually economical production. A. L. HENNE

The Canadian soapstone industry. HUGH S. SPENCE. *Can. Dept. Mines, Mines Branch No. 687*, 19-24(1928).—Canadian production of soapstone has increased from 167 tons in 1922 to 1411 tons in 1927, the remaining Canadian requirements of soapstone being imported from the U. S. and Scandinavia. There appears no reason why the entire market in eastern Canada should not be supplied with Canadian soapstone. L. W. RIGGS

Feldspar in the Sudbury region, Ontario. HUGH S. SPENCE. *Can. Dept. Mines, Mines Branch No. 687*, 7(1928).—The ore consists of a somewhat intimate mixt. of

quartz, feldspar and mica, so the mine product after sorting is crushed and passed on a picking belt. L. W. RIGGS

Asbestos industry in Canada. E. H. FREEMAN. *Can. Dept. Mines, Mines Branch No. 687, 69-79(1928)*.—In 1925 Canada produced 80.6% of the world supply of asbestos. The occurrences and methods of mining and milling are described. Of Canada's asbestos export, the U. S. takes 66%. In the production of spinning varieties Rhodesia leads with an output about double that of Canada. The poorer grades of asbestos rock, which in Africa or Russia are discarded, in Canada are manufactured into a non-spinning fiber for use in shingles, mill boards and cement. L. W. RIGGS

Asbestos in northern Ontario. HUGH S. SPENCE. *Can. Dept. Mines, Mines Branch No. 687, 6(1928)*.—A mine in Deloro township has been worked at intervals during the past 5 years. It yields a high quality of asbestos of similar compn. to that of the Quebec product, but the returns were not sufficient to warrant continuance of working. L. W. RIGGS

Graphite in Ontario and Quebec. HUGH S. SPENCE. *Can. Dept. Mines, Mines Branch No. 687, 8-11(1928)*.—Only 2 graphite mines and mills were in operation in 1926, one near Calabogie, Ont. and the other near Guenette, Que. Flow sheets of both mills are shown. Milling methods have recently been improved by the introduction of flotation methods. L. W. RIGGS

Anthraxolite near Sudbury, Ontario. HUGH S. SPENCE. *Can. Dept. Mines, Mines Branch No. 687, 5(1928)*.—The run of mine material contained 35% ash. The quantity of anthraxolite in sight is limited. L. W. RIGGS

Geology and lignite resources of the Marmarth field, southwestern North Dakota. C. J. HARES. U. S. Geol. Survey, *Bull. 775, 110 pp.(1928)*.—The geography, stratigraphy and structure are described. Analyses of 12 samples from this and 4 from adjoining fields are tabulated. These lignites are quite uniform in heating value, the B.t.u. of air-dried samples ranging from 8600 to 9970. This field also contains large quantities of fused or baked rocks formed during the burning of lignite beds. This porcellanite makes good track ballast, but is rather soft for highways carrying a heavy traffic. L. W. RIGGS

The Pumpkin Buttes Coal Field, Wyoming. C. H. WEGEMANN, R. W. HOWELL AND C. E. DOBBIN. U. S. Geol. Survey, *Bull. 806-A, 1-14(1928)*.—Extensive deposits of bituminous coal occur in this region, but will not be developed at present because of other deposits nearer the railroad. L. W. RIGGS

Supplementary observations on fossil rubber bark in ancient brown coal. W. F. OTHAN. *Centr. Min. Geol. 1927A, 209-11; Chem. Zentr. 1927, 11, 800; cf. C. A. 22, 933*.—From the Leonhardt mine at Frankleben, Germany, large pieces of fossil rubber bark were obtained, which showed clearly the paths of larvae of beetles. G. SCHWACH

Lavas of the Volcano Sumaco, Eastern Ecuador, South America. R. J. COLONY AND JOSEPH H. SINCLAIR. Columbia Univ. *Am. J. Sci. 16, 209-312(1928)*.—Lavas from different parts of the crater and slopes of the volcano are described petrographically with the aid of 3 photomicrographs of thin sections. Chem. analyses by Ledoux and Co. of 3 andesitic tephrites and 1 vitrophyric tephrite are reported. One of the andesitic tephrites from the rim of the crater gave: SiO_2 52.88, Al_2O_3 18.96, Fe_2O_3 2.92, FeO 2.88, MgO 2.22, CaO 6.40, Na_2O 5.09, K_2O 4.05, H_2O^+ 1.33, H_2O^- 0.85, TiO_2 0.68, P_2O_5 0.42, SO_3 0.01, MnO 0.13, BaO 0.42, sum 99.24%. The vitrophyric tephrite from the slope of the volcano differed from the other 3 samples in having lower SiO_2 and higher CaO , MgO and combined Fe oxides. L. W. RIGGS

The age and composition of the Whin Sill and the related dikes of the north of England. ARTHUR HOLMES AND H. F. HARWOOD. *Mineralog. Mag. 21, 493-542(1928)*.—The age of the Whin Sill and its assocd. dikes is post-Westphalian and the rocks may be divided into 2 sharply defined types. The Whin Sill proper and dikes running north of east are quartz dolerites. Chem. analyses reveal quite similar compns. Dikes of another series running north of west consist of tholeiites. The calcd. mineral compn. of the Whin Sill showed: quartz 6.76, alk. feldspars, Al_{10}O_3 4.45, plagioclase, $\text{An}_{46}\text{Ab}_{54}\text{Or}_{10}$ 40.40, pyroxenes 36.76, ores 8.90, apatite 0.67, calcite 0.70%. W. F. H.

Production of trachyte and phonolite from pyroxene andesitic magma associated with limestone. H. A. BROUWER. *J. Geol. 36, 545-8(1928)*.—Trachyte and phonolite were formed from andesitic magma in contact with a large xenolith of limestone. This observation is believed significant because of its bearing on the question of assimilation in the production of alk. magmas. W. F. HUNT

Halite and glauberite cavities in the Triassic rocks of central New Jersey. ALFRED C. HAWKINS. Rutgers Univ. *Am. J. Sci. 16, 361-2(1928)*.—These cavities were

observed in the red shales of the lower part of the Triassic near New Brunswick, N. J. Hopper-shaped halites had not previously been observed in the Triassic. The glauberites are more or less filled with calcite and barite. L. W. RIGGS

Oolites of artificial origin. W. H. TWENHOVEL. *J. Geol.* 36, 564-8(1928).—The calcite oolites described were formed in a hot water coil of a furnace. Each grain possesses a concentric structure and a nucleus of Fe oxide. The pptn. was brought about by liberation of CO₂ due to the heating of the water. W. F. HUNT

Bibliography of North American geology for 1925 and 1926. JOHN M. NICKLES. U. S. Geol. Survey Bull. 802, 286 pp.(1928). L. W. RIGGS

A new heating centrifugal [for separating minerals] (HÜTTER) 1. Ground water carriers of the lower Elbe region (KOCH) 14. A new rock and a new rhythmic process in rock. Rhythmic ring formation (STORZ) 2.

SCRIVENOR, J. B.: *The Geology of Malayan Ore Deposits*. London: Macmillan & Co. 216 pp.; 16 s. Reviewed in *Bull. Imp. Inst.* 26, 404-5(1928).

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, R. H. ABORN

Report of investigations: hydrometallurgical laboratory. R. J. TRAILL. *Can. Dept. Mines, Mines Branch No. 688*, 95-6(1928); cf. *C. A.* 21, 724.—The tests on ilmenite were completed and show that by obtaining a high metallization in the sponge process a very high-grade TiO₂ concentrate can be made, which is low in Fe and therefore better for pigment or other purposes. Further studies were made on the electrodeposition of Fe and on the recovery of Cu from chalcopyrite leach liquors. L. W. RIGGS

Aircraft metallurgy. HORACE C. KNERR. *Trans. Am. Soc. Steel Treating* 13, 723-52(1928).—An outline of the metallurgy of aircraft manuf. including specifications, mech. properties and processes for machining, forming, riveting, welding, brazing, foundry practise and corrosion prevention. W. A. MUDGE

Metallurgy and the aircraft engine. HENRY FISHBECK. Pratt & Whitney Aircraft Co. *Heat Treating and Forging*, 14, 1023-5(1928).—A brief review of the functioning of a metallurgical lab. in the operations of an aircraft motor company, the material inspection, heat treatment, and the ferrous and non-ferrous alloys used being discussed. J. BALOZIAN

Copper in 1926 (general report). C. E. JULIHN AND HELENA M. MEYER. U. S. Bur. Mines, *Mineral Resources of the U. S.* 1926, Pt. I, 559-615(preprint No. 23, published October 8, 1928). E. H.

Gold, silver, copper, lead and zinc in the eastern states in 1927. J. P. DUNLOP. U. S. Bur. Mines, *Mineral Resources of the U. S.* 1927, Pt. I, 1-6(preprint No. 1, published Oct. 2, 1928). E. H.

Consumption of primary or virgin tin in the United States, 1927. J. B. UMHAU. *Bur. Mines, Circ.* 6084, 2 pp.(1928). E. H.

The mining and smelting industry of Peru and its future. AD. DITTMANN. *Metal. Ers* 25, 225-38(1928).—A brief description of the metal resources and mining developments in Peru, especially the Cerro de Pasco Mining Corp. and Northern Peruvian Mining and Smelting Co. J. BALOZIAN

Ore from the J and L mine near Revelstoke, B. C. J. S. GODARD. *Can. Dept. Mines, Mines Branch No. 688*, 13-5(1928).—The ore is complex and consists principally of As, Zn, Pb and Fe sulfides with smaller quantities of Cu and Sb sulfides. The Au is assoc. chiefly with arsenopyrite and pyrite, and the Ag with galena. The gang is siliceous. Extn. by cyanidation was unsuccessful. A rough sepn. was obtained by selective flotation. Tabling of the flotation tailing was effective largely on account of the poor results in the flotation of the As. With improvement in the flotation of As, this step might be omitted. Arsenical gold ore from Mount Evelyn mines, Hudson Bay mountains, D. C. *Ibid* 16-27.—The sample was an oxidized arsenical gold ore in siliceous gang. Tests by concn., amalgamation, and cyanidation with or without roasting were unsatisfactory. Sizing, tabling, flotation and tabling; or sizing, tabling, flotation and cyanidation, or flotation, tabling and cyanidation gave the best recoveries. Concentration of the zinc and copper-zinc ores of the Alderson and Mackay mine, Rouyn, Quebec. *Ibid* 41-4.—The first type of ore consisted of Zn blende disseminated in a siliceous gang. By flotation this ore gave a concentrate with more than 45% Zn

and a recovery of over 90%. The second type was a heavy sulfide ore contg. 7.36% Cu and 6.53% Zn with small quantities of Au and Ag mainly associated with chalcopyrite. Good recoveries of the Zn, Cu, Au and Ag were obtained by selective flotation. Gold ore from the Gold Hill mines, Boston Creek, Ontario. *Ibid* 46-9.—A combination of 2 samples gave an ore contg. 2.3 oz. Au per ton in a siliceous gang with small quantities of Pb and Cu. Cyanidation was not practical because of high cyanide consumption and fouling of the soln. Amalgamation was satisfactory and should be inserted in the flow sheet. Flotation and cyanidation of the flotation tailing was satisfactory. Long Lake arsenical-gold tailings. *Ibid* 53-7.—Tailings from an old cyanide plant contained about 0.2 oz. Au and 0.06 oz. Ag to the ton and 2.0% As. The tests on a composite sample indicate that fine grinding and cyanidation is the better method of recovering the Au from these tailings. Water washing previous to cyanidation is recommended. The As in the ore is not worth attention at present prices. Concentration of a silver-lead-copper-zinc ore from La Rose mine, Kitsault River section, B. C. *Ibid* 57-9.—Selective flotation followed by tabling the flotation tailing is recommended for this ore. Ore from the Argonaut mine, Larder Lake, Ontario. *Ibid* 66-72; cf. C. A. 21, 725.—Flotation tests gave good results with each of the 3 samples and on mixts. of the samples. It is recommended that the diln. of the ball and tube mills be decreased to about 60% solids; that not more than 1.5 lbs. of lime per ton be added to the ball mill, and that a sol. reagent, such as xanthate, be used in place of coal-tar creosote and pine oil mixt. Gold ore from the Kitchener mine, East Central Manitoba. *Ibid* 72-9.—The ore contained about 0.75 oz. Au per ton, 90% of which was free and the remainder was assocd. with sulfides of Fe, Cu and Ni. Good recoveries were made by flotation and tabling, also by amalgamation, or amalgamation followed by tabling. Cyanidation was less satisfactory. Concentration of a gold-copper ore from English Brook district, East Central Manitoba. *Ibid* 84-6.—The gold was free and assocd. with small quantities of chalcopyrite, pyrite and arsenopyrite in a siliceous gang. This ore is low grade with Au 0.14 oz. and Ag 0.34 oz. to the ton and Cu 0.49%. Amalgamation followed by flotation and tabling appears to be the best treatment. Special sample of cyanide tailings from Dome Mines, Ltd., South Porcupine, Ontario. *Ibid* 93-4.—The sample carried about 10% of sulfides as pyrite and assayed 0.027 oz. Au per ton. The flotation of these tailings was successful. In continuous operation with return of the middling to the regrinding circuit, a recovery of 65% should be obtained. The addn. of Na_2CO_3 is considered essential in the flotation of a cyanide tailing. It ppts. the lime and brightens the sulfides. L. W. RIGGS

Contribution to the knowledge of silver carriers in the ores of lead-zinc veins. HANS EISELDER. *Metall Erz* 25, 350-1(1928).—In the Pb-Zn veins in the Harz and Rhine districts, the Ag occurs invisibly and principally in an isomorphous mixt. of Ag_2S and galena, and visibly in Sb-fahlerz. Galena is present in the primary layers, and fahlerz between this and chalcopyrite. Galena may displace fahlerz in the upper layers, and this may displace other minerals, thus causing Ag to be present in non-Pb products. Also, argentite is found as a secondary formation in the upper layers. The results of Seiler's investigations have been confirmed microscopically. J. B.

The advances in dressing technic in the year 1927. H. MADEL. *Metall Erz* 25, 428-37(1928).—A review. J. BALOZIAN

Copper ore dressing at the mine "Crosse Burg" in Neunkirchen (Siegerland). H. MIHSSNER. *Metall Erz* 25, 248-56(1928).—The Cu occurs raw, as the spar, and as CuFeS_2 (in mixt. with varying amts. of FeCO_3 and FeS_2). Pb, Zn and Mn ores also being present. Wet-mech. dressing is suited for the Cu and Pb-Zn ores, and flotation for the Cu spar. Development of the processes used is described, flow sheets being given. The most economical dressing of the Cu ore is made, in spite of variations in its compn. A brief description of the selective flotation of Cu and spar, and the units used is given. It is found to give economical yields of Cu, Fe and Mn. J. BALOZIAN

Sampling in the dressing of lead and zinc ores. KARL KOWARSCHICK. *Montan. Rundschau* 20, 546-9(1928).—A short description is given of the way sampling should be done to obtain a true av. A. L. HENNE

Early efforts in flotation of dry minerals. Historical. HENRY F. WOOD. *Eng. Mining J.* 126, 571-3(1928). E. H.

Flotation reagents manufactured in Canada. C. S. PARSONS. *Can. Dept. Mines, Mines Branch* No. 687, 1-4(1928).—Reagents used in flotation are described, and a list of Canadian mfg. firms is given. L. W. RIGGS

Concentration of the ores from the Dunwell Mines, Ltd., Stewart, B. C. C. S. PARSONS. *Can. Dept. Mines, Mines Branch* No. 688, 3-6(1928).—Samples from 8 veins were treated separately and compositely by flotation and tabling, the results showing

that by tabling the flotation tailing the Au recovery was increased from 11 to 20% with an addn. of less than 5% by wt. to the concentrate, that each ore can be concd. into marketable products, and that only the Zn concentrate would need previous cleaning. Concentration of lead-zinc tailings from the dump at the Notre Dame (Tetreault) Mine Notre-Dame des Anges, Quebec. *Ibid* 28-30.—The Zn could readily be recovered by flotation. It was possible to obtain a Pb concentrate contg. over 30 oz. of Ag and 3 to 4% Cu but low in Pb, the best grade being 22.8%. A quantity of gang floated with the Pb and prevented the formation of a richer concentrate. Concentration of a complex gold and silver ore from Alberni, B. C. *Ibid* 32-4.—The sample was an oxidized ore contg. Au, Ag, Cu, Pb and Zn. On account of the oxidized condition of the ore, selective sepn. by flotation between Cu, Pb and Zn was not practicable. The recoveries of Au and Ag were not high but were fairly satisfactory considering the oxidized condition of the ore. Concentration of the zinc ore from the John Bull and Florence claims, Powell River section, Nanaimo Mining Division, B. C. *Ibid* 49-53.—The samples were similar and consisted of Zn blende, chalcopryrite and pyrite in a limestone gang. The John Bull ore could not be concd. by gravity methods but gave good results with flotation as did the Florence ore. Less than 1% of Cu is in the latter ore. Concentration of a lead ore from the Forbes galena mine, Perth Road, Ontario. *Ibid* 60-5.—The ore contained galena in a calcite gang assocd. with pyrite and Zn blende. Pb present, 2.03%. From a mill test, a flow sheet was worked out which is recommended for use with these ores. Concentration and separation of the values in a lead-zinc-gold-silver ore from Bunker Hill claims, Alice Arm, B. C. *Ibid* 79-82.—The sample was a heavy sulfide ore contg. galena, Zn blende, Au and Ag. Five flotation tests were run, a table test and a cyanide test. The production of Pb concentrate high in Fe sulfides is recommended in order to recover as much Au as possible. A grade of 50% Pb works well. The tests indicate that 90% of the Pb may be recovered from a concentrate contg. 50% Pb. and 85% of the Zn from a 45% Zn concentrate. Approx. 50% of the Au and 80% of the Ag can be recovered in the Pb concentrate. The Ag in the Zn concentrate can be considered as recovered. Concentration tests on ore from the Giant Mine, Spillamacheen, B. C. *Ibid* 82-3.—The sample consisted of galena assocd. with a barite gang contg. Pb 10.1%, BaSO₄ 47.1, other insol. material 36.1, Ag 1.36 oz. per ton. The Pb was easily concd. by flotation. Barite was tailed from the flotation tailing which runs high in BaSO₄. Whitewater lead-zinc tailings from Retallack, B. C. *Ibid* 87-93.—The tailings were from a gravity concn. mill and contained Pb 1.46%, Zn 6.65% and Ag 7.31 oz. per ton. Selective flotation was not feasible with these tailings. It is not possible to make definite recommendations for the treatment of this material. Selective flotation as applied to Canadian ores. *Ibid* 112-34.—A general description is given of recent flotation practice. Twelve typical examples, illustrating the treatment of a variety of ores, are worked out experimentally. Four full page photographs of modern flotation machinery are shown. L. W. R.

Concentration of the copper-gold ore ("F" ore-body) of the Noranda mines, Ltd. Rouyn, Quebec. C. S. PARSONS AND J. S. GODARD. *Can. Dept. Mines, Mines Branch* No. 688, 6-13(1928).—The samples consisted of heavy sulfide ore contg. chalcopryrite, pyrrhotite, pyrite and Au. The object of the work was to learn if this type of ore could be concd. into a body which would contain the Au and Cu, the greater portion of the pyrite and pyrrhotite to be eliminated in the tailing product. The results of the magnetic sepn. test show that pyrrhotite does not carry the Au. Flotation tests prove that the Au is not entirely assocd. with the Cu. Freshly mined ore gave higher results than aged ore, therefore oxidation should be guarded against. Good results were obtained by using NaCN with Na₂CO₃. L. W. RIGGS

The heat content and the specific heat of some slags at high temperatures. SAKURU UMINO. *Science Repts. Tohoku Imp. Univ.* 17, No. 5, 985-96(1928).—The heat content and the mean sp. heat were obtained for 2 kinds of slags, from a blast furnace and a basic open-hearth furnace, at temps. ranging from 100° to 1500° by the calorimetric method of mixts. In general both the heat content and the mean sp. heat of the slags are very large as compared with those of metals, and increase with the rise of temp. DOWNS SCHAAF

Note on the roasting of Rand refinery sweepings containing silver chloride. J. HENDERSON. *J. Chem. Met. Mining Soc., S. Africa* 29, 31-2(1928).—Exptl. results on Rand refinery sweepings and pyrite concentrates from the West Rand Consolidated Au mine show that Ag losses are reduced from 12.7% to 1.1% by roasting a mixt. contg. 60% sweepings and 40% pyrite. W. H. BOYNTON

Working up wastes in industries dealing with precious metals. FRITZ MICHEL. *Chem.-Ztg.* 52, 733-4(1928).—Solns. contg. precious metals are pptd. with sulfides,

Zn, Al, etc., or are evapd. and treated as waste matter. Solid wastes high in metal values are either smelted directly into a crude bullion, or are first ignited, then treated with a magnet for the removal of Fe compds., and finally melted down with suitable fluxes. Small scale refining by the metal worker himself is rarely successful. Most industrial waste is first roasted, mixed thoroughly, ground, treated with a magnet, and then melted with soda and borax. Wet methods for extg. precious metals from waste have not been profitable. Often the wastes are briquetted (with a binder like $\text{Ca}(\text{OH})_2$) and sold to a Pb-smelter, where they are used as part of a regular furnace charge.

W. C. BRAUGH

Copper Queen smelter. P. G. BECKETT. *Eng. Mining J.* 126, 682-3(1928).—The expansion of this smelter since its erection in 1904 is outlined and the new roaster reverberatory plant installed in 1927 is briefly described. "Pioneer" troubles are still being eliminated. For March, April and May, 1928 the reverberatory furnaces treated 998 tons (907,182 kg.) solid charge per furnace day with a gross fuel ratio of 0.405 bbl. oil per ton (equiv. to 2,562,000 B.t.u. per ton (909 kg.)). Waste-heat steam production was 7.35 lb. (3.35 kg.) steam from and at 100° per lb. of oil burnt in the reverberatories. Roasters averaged 237 tons (215,433 kg.) per day solid charge, per furnace day, from 23.7% S to 12.9% S. Fuel consumption was 0.001 bbl. of oil per ton of charge. The combined direct gross cost of roasting, reverberatory smelting, and dust recovery was about \$1.27 per ton; fuel credit is 41c per ton.

W. H. BOYNTON

Selective flotation. WM. T. MACDONALD. *Eng. Mining J.* 126, 678-82(1928).—Selective flotation of all mill heads at Copper Queen and Nacozari mines differs in 3 practical ways: (1) fines grinding is required at Copper Queen because of a closer inter-association of sulfides; (2) the Copper Queen uses Forrester cells, and Nacozari uses MacIntoch cells; and (3) sep. addnl. steps of concentrate cleaning were added at Nacozari because no new construction was necessary. Lime protects xanthate by impeding its pptn. by sol. Fe, though permitting the corresponding reaction with sol. Cu. Close control is essential to the maintenance of the best av. results in all the plants. The original mill flow sheet is compared with present practice at Nacozari and at Copper Queen; and a typical flow-sheet for Nacozari for 1927, with metallurgical results is given.

W. H. BOYNTON

Colorimetric copper method proves valuable control tool. ANON. *Eng. Mining J.* 126, 683(1928).—Samples of feed, concentrate, and tailing are taken, de-watered in a pressure filter and dried on a hot plate. This sample is cut down, weighed and given a standard HNO_3 digestion. Fe is removed by NH_4OH and the Cu detd. in the soln. by comparing with a soln. derived from a standard pulp of known Cu content in a colorimeter. Results are obtained in 30 min. and check standard KI assays within 5% of the Cu content.

W. H. BOYNTON

Concentration trends. W. B. CRAMER. *Eng. Mining J.* 126, 675-7(1928).—This and the 3 preceding abstrs. deal with operations at the plants of the Phelps Dodge Corp. Pilot plant operations at Bisbee and Nacozari between 1918 and 1920 led to concentrator changes. Two-stage grinder circuits reduced the material to 14-mesh, and then to 48-mesh. The removal of more pyrite and insol. produced a higher grade concentrate, reduced smelting costs, and smelter and slag losses, because of the partial removal of slag-forming constituents. These steps involved: elimination of all gravity processes and making flotation the sole major process; sufficiently fine grinding to sep. mineral from gang and to sep. the Cu minerals from pyrite; changes in the flotation flow sheet and arrangement of roughers, cleaners, and re-cleaners; and changes in the character and amts. of flotation reagents, including lime. The trends are for a continuation of simplicity of flow sheet, finer grinding, improved classification, and improved flotation work. Grinding equipment at individual mines is noted and 8 tables show the improvements in costs of operations. Future progress in costs and improved metallurgy is largely assocd. with crushing, grinding, and classification problems.

W. H. BOYNTON

Handling problems in the open-hearth. J. RICHARDSON. *Blast Furnace & Steel Plant* 16, 1326-8(1928).—Suggestions to the material-handling engineer from the operations of the open-hearth show a broad field for constructive planning.

E. H.

A tilting regenerative reverberatory furnace for foundry use. HESS AND H. PINSL. *Giesserei* 15, 281-9(1928).—The construction of a 25 ton tilting (by an hydraulic cylinder operating at 30-40 atm.), reverberatory, oil-fired furnace employing a preheated blast is outlined. Between the movable upper and the stationary lower portions of the furnace is a water seal, which is equally effective in either the tilted or the rested positions. One man can take care of the dampers, and for handling the oil and regulating its flow to the burners. The usual charge consists of about 80%

liquid blast furnace Fe and 50% cupola Fe scrap. The intended compn. of the cast Fe can be obtained, exactly in this type furnace, there being very small loss during the fusion. To det. the effect of progressive overheating (in this and a similar 5 ton furnace) on P-rich cast Fe, tensile tests are made. Thus, the bending strength increases about 40%, the breaking strength from 14 to 20 kg., the Brinell hardness from 187 to 217, and the sp. gr. from 7.08 to 7.17. For good tensile properties, normally overheated Fe must be poured immediately on drawing. During the fusion the temp. increase is apparently rapid, the Fe being overheated to 1375–1400° for some time before drawing. There is no change in the Si, Mn, P and S content of the Fe during fusion. The loss in C during overheating is 0.1–0.15%, that in the remainder being 0.3%. The graphite, also, decreases from 2.85% to 2.42%, or from 83% of the total C to 81.5%. The influence of overheating on the graphite formation is shown clearly by photomicrographs.

J. BALOZIAN

The zone formation in the cupola furnace and its influence on the smelting process. K. MÜHLBRADT. *Giesserei* 15, 335–9 (1928).—Previous results being used, an explanation of the combustion and smelting processes in the cupola furnace is attempted. From the gas-current lines in the ideal gas producer, the zone formation in an ideal present-day cupola furnace is developed. Here, the oxidation zone extends up from slightly below the tuyère level to the funnel-shaped neutral zone (I); the lowest point of this lies on the furnace axis, and develops upward to the sides. In the smaller furnaces the funnel-shape of I is the least apparent, in middle-sized furnaces the lower end of the funnel is about on the tuyère level, while in the larger (also smaller ones with insufficient blast) the funnel is open and I bends back below the tuyère level to the furnace walls. From a consideration of the effects of various types of I and the oxidation zones on the course of combustion and smelting in the ideal gas producer, it is seen that these processes must be so coupled that the smelting terminates directly above I. As the temp. is highest here, the most economical combustion takes place, the total heat being utilized in smelting and overheating the Fe. These conditions are not entirely fulfilled in the cupola furnace because of differences in the form of I and the charged Fe. When the coke-bed is so filled that I is raised to the top edge of the funnel, the size of the reduction zone and therefore the heat consumption increases, a considerable amt. of CO appearing in the waste gases. This disadvantage may be eliminated by keeping the coke-bed low, the Fe charge thus sinking into the oxidation zone and cutting through the hottest part of I. In the first case relatively hot Fe is produced with high fuel consumption and unsatisfactory compn. of the waste gases, while in the second there is more satisfactory combustion with lower Fe temps.

J. B. •

Points for the construction of small converters. E. PIWOWARSKY. *Tech. Hochschule Aachen. Giesserei* 15, 314–5 (1928).—The importance of correct proportions of the vol., interior height and diam. of the body of a converter are briefly stressed. The dimensions, from expt., for a 2-ton converter are given. The method of sepg. the blast-lead from the body in the Zenzen converter, the most widely used small unit in Germany, is briefly described.

J. BALOZIAN

New theory of the blast-furnace process. F. WÜST. *Stahl u. Eisen* 48, 505–6 (1928).—The theories advanced to explain the great fuel-saving effect of the hot blast introduced by James Beaumont Neilson are reviewed. An outline of a new theory is given in 14 points; the exptl. evidence of this theory will be published later. In front of each tuyère, there is an oxidizing zone, which reduces the efficiency of the blast furnace; methods to reduce the oxidizing zone increase the efficiency. Such methods are: the use of charcoal instead of coke, hot blast, Linde-air, oil-injection and the enlargement of the furnace at the oxidizing zone. Because of this re-oxidation at the tuyères the incorporation of foreign (alloying) elements must take place above the tuyères. The reaction $2\text{CO} \rightleftharpoons \text{CO}_2 + \text{C}$ improves the reducing work of the furnace; this reaction is increased by the use of hot blast. Scaffolding is not only regulated by the type of ores (porosity) but also by the temp. of the throat. The so-called direct reduction of Fe, Si and P occurs almost entirely above the tuyères and is caused by the C liberated according to the equation above. Pig Fe takes up most of the impurities in the shaft by a cementation process. Only a small part of the impurities is taken up by direct reduction from the slag. Analysis of the flue gas or of the gas from any part of the furnace does not give sufficient evidence for the evaluation of the working of the furnace.

J. A. SZILARD

Slag types for lead blast furnaces. FELIX VON SCHLIPPENBACH. *Metall Erz* 25, 343–50 (1928).—The rules, that in Pb slags an increase in ZnO is accompanied with an increase in the FeO and a decrease in the CaO and SiO₂, and an increase in Al₂O₃ with an increase in the CaO and a decrease in the FeO and SiO₂, are shown to be in-

correct. From 6000 slag analyses, obtained during 30 years, it is concluded that: (1) ZnO and Al_2O_3 are not slagged, but are, independent of the ratio to one another, completely dissolved by silicates; (2) all slags contg. $FeO \cdot SiO_2$, $2CaO \cdot 3SiO_2$ and $CaO \cdot 2SiO_2$ are uniformly good; (3) corresponding to the $ZnO + Al_2O_3$ taken up by the slag, SiO_2 , CaO and FeO are changed, without alteration in their relationships, proportionally to one another. By calcg. the slag compn. for $FeO \cdot SiO_2$ and $CaO \cdot 2SiO_2$ and using the ratio of $FeO:CaO = 2:0.5 - 2:2$, 14 types of slags are obtained. In the first table are listed acid slags and in the sec. basic slags. On the assumption that 0-20% $ZnO + Al_2O_3$ is present, the SiO_2 , CaO and FeO in slags are calcd. and given in Table 1. The min. and max. amt. of SiO_2 is 28-38%, of FeO is 24-50%, and of CaO is 12-30%, resp. When one is working with $FeO \cdot SiO_2$ and $CaO \cdot 2SiO_2$, the slag should contain not over 40% and below 26% FeO , and not over 22-23% CaO . In Table 2 are given the results of similar calcns. made for slags high in $ZnO + Al_2O_3$ and low in SiO_2 , the latter being present in sufficient quantity to form $FeO \cdot SiO_2$ and $2CaO \cdot 3SiO_2$. Limiting values assumed for FeO are 26-40% and for CaO are 12-24%, the min. for SiO_2 27%. The calcd. slag compns. compare well with the values given in the literature. J. B.

Slag types for lead blast furnaces. P. TAFEL. *Metall Erz* 25, 430-40 (1928).—The paper of von Schlippenbach (preceding abstr.) is discussed. T. considers that the relationships existing in Pb slags are not as simple as von S. supposes. Aluminates and silicates, other than those assumed by von S., are present under the conditions. A fixed rule, doubtlessly, cannot be given for producing good slags from gang of varying compn., using a min. of flux. The tables given by von S. serve for empirically detg. slag compns. J. BALOZIAN

The metallurgical aspects of cast iron. P. W. BLACKWOOD. *Trans. Am. Soc. Steel Treating* 13, 1023-38 (1928).—A discussion of the effect of addns. of Ni, Cr, W, Mo, V, Ti, Cu, and Al. W. A. MUDGE

The manufacture of pig iron in Natal. J. E. HOLGATE. *J. Chem. Met. Mining Soc. S. Africa* 29, 32-6 (1928); cf. C. A. 22, 1937.—A discussion by G. H. Stanley. A certain amt. of coke or other fuel must be burnt in the hearth. The amt. of coke consumed by soln. depends upon its "reactivity" and on the compn. and temp. of the gas to which it is subjected, increasing with CO_2 content and temp. Natal coke showed % of cell vol. of 51-7% for beehive coke, while oven coke was lower—in one case about 31%. The savings claimed when smelting raw carbonate may be due chiefly to most of the original 5% C reaching the hearth, functioning there as fuel. The 5% C is shown by calcn. to be sufficient to reduce nearly 97% $FeCO_3$. The gas evolved from the lumps will have much less solvent activity for coke in its vicinity, than that from a straight carbonate. Only half the oxide will be left to be reduced by the rest of the gas, which should not become so oxidized nor in consequence dissolve as much coke. Calcns. are shown which bear out the assumptions. "It is diminished soln. loss when smelting black band ores that enables a higher % of the coke charged to get down to the hearth and function there as fuel. W. H. BOYNTON

Report of research committee on yield point of structural steel. M. O. WITHER. *Proc. Am. Soc. Testing Materials*, Reprint from Vol. 28, Part 1, 28 pp. (1928).—Two series of tests were conducted by 3 mill labs. and 2 college labs., to ascertain the effect of speed of loading and method of detecting the yield point of C, Ni and Si structural steels. Increasing the speed of loading from 0.05 to 2.0 in. per min. caused a 7% increase in the yield point in tension for Ni steels, 9% for C steels and 12% for Si steels. At a speed of 0.2 in. per min. the yield point, by drop of beam, was 600 to 1000 lbs. per sq. in. higher than at a speed of 0.05 in. per min. The max. range in drop of beam yield points, considering all speeds, was 10% for C steels, 6% for Ni steels, and 11% for the Si steels. Of the 4 methods used in detecting the yield point the multiplying divider method was the most reliable, and gave values slightly less variable than the drop of beam method, which is the simplest and quickest, and in most cases sufficiently reliable. DOWNS SCHAAP

Recrystallization of metals. ENRICO CREPAZ. *Ann. scuola ing. Padova* 4, 43-52 (1928).—It is well known that the mech. properties of metals or alloys depend on their mech. and thermal treatment. The dimensions of the crystals can be represented according to strain and to annealing temps. and thus diagrams of recrystn. obtained. Various theories are discussed to explain the relation between the mech. properties and the structure of the metal or alloy: i. e., Tammann's theory (properties depend on the strain necessary to produce the change in structure as well as orientation of the crystals; the theory of an amorphous modification; and the theory which considers the changes in elastic forces. None explains all phenomena completely. A. W. C.

The plastic deformation and fracture of metals. WALTER ROSENHAIN. *Natl.*

Phys. Lab., Teddington, England. *Intern. Congress Testing Materials 1927, I, 50-80.*—The problems considered are, the mechanism by which cold-worked metals are rendered harder and stronger, and the mechanism by which rupture occurs. Slip starts along a few favored planes of a crystal, but those planes become hardened, and other slip planes then come into use. A breaking down of the lattice structure, like local melting, gives disturbed or amorphous layers along the slip planes, and these layers prevent the recovery of the intervening lattice from the elastic distortion in the same way as solute atoms of a different metal cause lattice distortion. General straining of the lattice is not the cause of hardening by cold working, because even after heavy plastic distortion of a crystal there is some elastic recovery, and because increasing cold work gives a progressive increase of hardness. Beilby's theory of hardening from amorphous layers along slip planes is thus modified. From a study of d. changes it is deduced that the disturbed layers may be very thin, or less than 100 atoms in thickness. The temporary semi-plastic condition of mild steel after straining just beyond the yield point, and the failure to form Neumann bands by impact in freshly strained steel, indicate a temporary mobility of the disturbed layers; this is due probably to the presence of irregular or potential but non-effective at. linkages. The time required for recovery is less at higher temp. because of the increased mobility of the atoms. In fatigue tests, elastic agitation has about the same effect as increased mobility due to heating. In corrosion-fatigue, chem. attack occurs along the disturbed layers formed by slip. When slip is no longer possible, fracture occurs by a tearing action due to concn. of stress at irregularities of structure or surface. When a crystal aggregate is strained there is movement at the boundaries and rotation of the lattices toward a preferred orientation, involving a break-down of the lattice structure near the boundary. The change of orientation at the boundary between 2 crystals is too sudden to be accounted for by a bending of the 2 lattices, and must be effected by an irregularly arranged practically amorphous layer of atoms. The strength of boundaries shows that they cannot be merely loose points of contact of different lattices, but are regions of strong cohesion. The strength of x-ray reflections from cold-worked metal shows that they are obtained not from only a few crystals that happened to be favorably oriented, but that the orientation of many crystals must have changed to the favorable direction. This is due to mass-rotation rather than a rotation of the crystal axes which would be practically the same as recrystn. The rotation of atoms within the crystals must cause a much greater amt. of disturbed arrangement than mere slip, and near the boundaries a thicker region of crystal fragments embedded in a mass of irregularly arranged atoms must exist. Truly rational testing depends on the development of a complete explanation of the mechanism of deformation and rupture. G. F. C.

The fatigue of metals. H. F. MOORE. Univ. of Ill., Urbana, Ill. *Intern. Congress Testing Materials 1927, I, 297-303.*—Most engineering formulas for the strength of materials were developed by civil and not mech. engineers, and are accurate only for static stresses of large structural members. Experience with axles, and Wohler's rotating beam tests, showed that failures might take place under alternating stresses at lower loads than called for by the accepted engineering formulas. The concept of a perfect elastic limit as a stress below which Hooke's law holds and repeated loadings are harmless depended on the postulate that material is continuous and homogeneous. Metallography has shown that this postulate is not true, except statistically on a large scale. Basquin in 1910 showed that the fatigue tests then reported did not indicate a definite endurance limit for materials. Later more extensive endurance testing resulted in reestablishing the existence of a limit of stress below which a metal will withstand an indefinite no. of reversals without fracture. There is a fairly good correlation between the endurance limit and tensile strength, the former in ferrous metals being about half the latter. Fatigue failure, as studied with the microscope, seems to be the spreading of localized fracture, rather than merely a slip. Irregularities in stress distribution weaken metal in fatigue, but not as much as the mathematical theory of elasticity would predict. Slip under repeated stress may occur without the development of a fatigue crack. The exact cause of origin of a fatigue crack is not known, but it is not known to occur without slip. Clean metal, smooth surfaces and avoiding sudden changes in section will improve fatigue strength. Rosenhain in discussion stated that fatigue failure has been known to occur without slip; failure in fatigue occurs by the exhaustion of ductility as in tension, but at a lower stress because the slip is in both directions.

GEO. F. COMSTOCK

The development and application of high-power metallography and the ultra-violet microscope. FRANCIS F. LUCAS. Bell Telephone Lab., N. Y. *Intern. Congress Testing Materials 1927, I, 123-56.*—The resolution obtainable in microscopy can be

increased by using objectives of higher numerical aperture, and light of shorter wave length. A detailed description, with illustrations, is given of the Bell Telephone metallographic lab. in N. Y. city. The microscopes and cameras are supported on sponge rubber disks, 6 in. in diam. and 1 in. thick, to eliminate vibrations. A rigid metal clamp for mounting specimens is also described, requiring no plasticine. The Zeiss lenses are raised. The ultra-violet equipment should give, theoretically, twice as high resolution as the ordinary equipment. Cd electrodes were better than Mg. Focussing, which requires a fluorescent screen, or trial exposures, is difficult and rather uncertain. Some interesting and valuable results have been obtained with ultra-violet light, but this development seems to be still in progress. The monobromonaphthalene objective of 1.6 numerical aperture was applied to metallography with good results. A suitable immersion fluid of n higher than 1.65 should be found. Specimens of soft metals were difficult to prep. properly for microscopic examn., but by the use of a Jung microtome, with the knife ground to cut a section 2 microns thick, surfaces of Pb free from defects were prepd. L.'s investigation of a fatigue crack in Armco Iron is described, showing that this metal was full of inclusions, some of which were found, by observation at high magnification, to lie in the path of the crack. His work on the structure of hardened steel is also described. Martensite needles were found to be aggregates, probably of α Fe and Fe₃C, and marked a decompn. along the octahedral planes of austenite. These investigations are still in progress. White needles found in hardened steel are probably austenite, perhaps in a sub-microscopic stage of decompn. The progressive formation of troostite and pearlite on tempering is described, and the structure of troostite was resolved, in part, into α Fe and carbide in fine particles, by high magnification. C. Benedicks in discussion shows that useful magnification may be as high as 1500 diam. in spite of the former theory.

GEO. F. COMSTOCK

Microscopic metallography in relation to impact and endurance tests. P. FORCELLA Royal Exptl. Inst. of Communications, Italy. *Intern. Congress Testing Materials 1927*, J, 229-52.—Impact tests were made with a Charpy machine made by Amsler, using specimens 10 by 10 by 55 mm. with semi-circular notch according to Mesnager. The endurance tests were made with an Amsler machine giving alternate bending by repeated shock, these specimens being rods of 11 mm. diam. They were notched to avoid working, by blows of the machine, the surface where fracture started. Tensile tests were misleading as they often showed good results for material which was weak in impact, and did not explain failures in service. Impact tests agreed with service results and microstructures, and samples giving good impact results always were satisfactory in the tensile test. Illustrations of a tire, a rail, a boiler plate, and a locomotive draw-bar are given, all having failed in service, and giving good results in the tensile test, but poor impact results and microstructures. Two rails that stood severe treatment in service gave good impact results and microstructures. Impact test specimens should be notched perpendicular to the surface of hot-working, to avoid unreliable and discordant results, and splitting or deformation of the specimen. The reasons for this are explained in detail and illustrated by photographs and by tabulated results. Notching of the endurance test specimens was considered advantageous, to localize the fracture at a measurable cross-section. Two series of tensile or hardness, impact and endurance tests of steels are reported, with corresponding microstructures, showing the superior properties attainable by heat-treatment. Specimens from a good rail endured 5000 to 6000 blows, while those from a bad one that broke in service showed about $\frac{1}{4}$ as much endurance. The endurance results agreed with the microstructure and service results, and varied with the impact results. Great hardness tended to give poor endurance, and high tensile results tended to give good endurance. Expts. are needed to det. for each metallic product the impact and tensile values assocd. with the max. endurance in service.

High-temperature treatments of castings and forgings as evidenced by core drill tests from heavy sections. W. J. MERRIN. *Trans. Am. Soc. Steel Treating* 13, 1-21 (1928).—Considerably higher temps. and extended soaking periods are necessary to give proper grain structure to permit the use of higher service stresses in design of large size elec. machinery (10,000-15,000 lbs.). A recommended practice of heat treatment is given. W. A. MUDGE

Influence of thermal and mechanical treatment on the resistance of steel to repeated stress. H. RABOZÉE. Ecole Militaire, Brussels, Belgium. *Intern. Congress Testing Materials* 1927, I, 291-6.—Resistance to repeated stress is an important property of a material and should be considered in design. Heat treatment and mech. working affect fatigue resistance, but may affect other properties, especially impact resistance, in the opposite manner. Tensile, impact and hardness test results are compared with the fatigue resistance of several steels of 0.25 to 0.29% C. The repeated shock machines of the Amsler and Cambridge types were used; they gave results of the same order as the rotating beam fatigue machine. The results after various heat treatments are tabulated and plotted as curves; and another series of tests of similar steels annealed and cold-worked is also reported. The endurance results were regular and consistent and gave smooth curves. The resistance to fatigue by repeated shock varied with the tensile strength and elastic limit, and inversely to the impact resistance. The relation to the elastic limit was more regular than to the tensile strength. Annealing at 550° gave a fatigue resistance much greater than annealing at 650°, without involving an excessive reduction in impact resistance. Cold-working led to an increase in the fatigue resistance, but with a decided fall in impact resistance. GEO. F. COMSTOCK

Slag (solid non-metallic) inclusions in iron and steel. C. BENEDICKS AND H. LÖFQVIST. *Intern. Congress Testing Materials* 1927, I, 265-90.—All solid non-metallic inclusions are called "slag," and they are classified as indigenous, due to reactions occurring in the molten metal, and exogenous or mechanically admixed foreign particles. The former are more important, and their complete study requires a knowledge of the slag-metal equil. diagrams. The Fe-S equil. diagram is shown, the soly. of S in solid Fe being estd. as 0.015 to 0.020%. The diagrams of the Fe-S-C and Fe-Mn-S systems are also illustrated. Fe₃C probably dissolves considerable FeS at high temp. C assists the sepn. of MnS from the melt. A complete Fe-O equil. diagram is given. Fe dissolves 0.21% O at the m. p. (1520°) and 0.05% at atm. temp. FeO forms a eutectic with Fe₂O₃ at 1200° and is unstable below 570°. Diagrams of the following systems are also given: FeO₂-MnO; FeO-SiO₂; MnO-SiO₂; FeO-MnO-SiO₂; Fe-FeS-Fe₂O₃; and FeO-MnO-MnS. The last would not be much affected by Fe or FeS. Systems including P are also considered briefly. Microscopic methods for identifying inclusions are mentioned, but not given in detail, and the gravimetric detn. of residues after soln. of the metal by Br or other reagents is briefly discussed. Slag particles rise out of molten metal quicker if larger and of lower d. Lowering of the m. p., as by Mn, facilitates coalescence into larger particles. Slag inclusions may slightly decrease the grain size of metal by retarding recrystn. Irregularities of structure, due for instance to pearlite particles or slag inclusions, are shown to cause banded structure on working because of the retarding influence of the harder particles on flow. Conc'n. of ferrite around inclusions is probably due to soly. of the non-metallic matter in the Fe, as explained by Mahin. Flakes are due to a combination of causes, originating at segregated spots of slag or other defects, and being developed later as "shearing fissures" by thermal or possibly mech. strains. Inclusions in general are detrimental to corrosion resistance. Basic Bessemer steel is usually dirtier than open-hearth, but high-C acid Bessemer steel should be cleaner. The addn. of CaO to acid slag helps to make cleaner steel. To prevent the formation of inclusions, the oxidation products of the deoxidizers used in the steel should have a low O pressure and must be easily rejected from the melt. In discussion, J. Bartel described a boiler plate contg. only 0.06% C which was brittle and showed much included oxide slag, and H. Fowler stated that the elongation, and the life in service, of locomotive crank-axes depended on their freedom from slag inclusions. An extensive bibliography is given. GEO. F. COMSTOCK

Inclusions in iron. C. R. WOHMAN. *Trans. Am. Soc. Steel Treating* 14, 81-125, 255-99, 385-414, 539-75 (1928).—An exhaustive photomicrographic study of FeO, MnO, FeS, MnS, and silicates and their combinations. W. A. MUDGE.

Notes on tempered cast iron: shrinkage. RUDOLF STOTZ. *Giesserei* 15, 297 (1928).—The unrestricted shrinkage of crude cast Fe is 2%, and, for similar methods of fusion, is practically independent of the chem. compn. However, the lower the C

content of the casting, the greater are the shrinkage and the danger of pipe. The change in length during annealing is dependent on the method used and on the chem. compn. The greater the temper C formation, the greater is the expansion due to annealing. The greater the thickness of the wall the less will be the shrinkage.

Notes on tempered cast iron. Differences between "white" and "black" tempered cast iron. RUDOLF STOTZ. *Giesserei* 15, 315-6(1928).—The properties and uses of tempered white and black, black-heart, and boring cast irons are briefly noted.

J. BALOZIAN

The economic value of nickel and chromium in gray iron castings. D. M. HOUSTON. *Trans. Am. Soc. Steel Treating* 13, 105-20(1928).—A discussion of the elements and conditions which influence the form of graphite and the constitution of combined C, with practical applications in heavy sections and pressure work, Diesel engine liners, forming dies and automobile cylinders. Si is a graphitizer and softener; Cr forms carbide and hardens; Ni destroys carbide and hardens the matrix. One point of C is equiv. to 3 points of Si, 3 of Cr, and 6 of Ni in reducing chill.

W. A. MUDGE

Some experiments on iron. LAWRENCE G. KNOWLTON. Cornell Univ. *J. Phys. Chem.* 32, 1572-95(1928).—Total C in Fe was detd. electrolytically by placing Fe turnings in a Pt dish serving as the anode, adding 10% Na_2SO_4 soln. and using a strip of Cu as the cathode. After a short time the $\text{Fe}(\text{OH})_3$ formed is poured off the fresh Na_2SO_4 added; this is repeated several times until all of the Fe is dissolved. The combined Na_2SO_4 solns. are treated with HCl and the insol. C is collected on a Gooch crucible. 2.27% C is obtained for a sample having 2.19% C. With sheet iron as a cathode in an ammoniacal NH_4NO_3 soln. the corrosion is exceedingly slow and more C than the graphitic C remained undissolved. If KMnO_4 soln. is added to the Fe prior to the addn. of acid, with white Fe the C remaining undissolved can be brought up to total C. With gray Fe the C values are low because of the oxidation of the graphitic C. Sn was added to molten gray Fe in an induction furnace; on pouring into sand only a part of the graphitic C is thrown out. Increasing to 16% the % of Sn added increases slightly the amt. of graphite pptd. Two layers form at this point and addn. of more Sn has little effect. It seems probable that the C is present in molten Fe either as dissolved C alone or in equil. with Fe_3C . Addn. of PhNH_2 to 10% H_2SO_4 at 50-60° cuts the amt. of H_2 evolved from a strip of Fe from 40 cc. to 5 cc. In the presence of PhNH_2 the H over-voltage rises at the cathode and the decompn. voltage is 0.05 v. higher. It was found that gray Fe boiled with either NaCl or Na_2SO_4 will reduce PhNO_2 to the same extent. Tests indicate that the Fe did not become passive during the heating with NaCl. Sn is not made passive in concd. HNO_3 by the formation of a film of $\text{Sn}(\text{NO}_3)_2$, since washing with H_2O does not remove its passivity. A Pt electrode connected to a bar of Sn in HNO_3 (sp. gr. 1.442) renders it passive. Sn also becomes passive when made the anode in HNO_3 (as low as sp. gr. 1.344) with a Pt cathode. Passivity is brought about by the discharge of H_2 at the cathode and the effect of nascent O at the anode.

D. H. POWERS

The question of the carburization of steel scrap in the cupola furnace. PAUL LORINSER. *Giesserei* 15, 366(1928).—Fusions, with addn. of 40% and 60% steel, are made in 4 cupolas of different construction and size to det. if they show the same tendency to carburize. It is seen that the C content varies not only in the same furnace with similar charges, due partly to changes in the exptl. conditions, but that also different furnaces carburize differently. By careful supervision of the furnace processes, however, the C content may be kept within narrow limits. The estd. carburization values tend to decrease with increase in the amt. of added steel and, also, with increasing Fe temps. A high Fe temp. is a criterion for a min. carburization of steel in the cupola. In L.'s opinion, the ratio of $\text{CO}_2:\text{CO}$ influences the equil. in the absorption processes during carburization.

The melting or molten stage of steel manufacture with particular reference to the deoxidizing, refining and contamination phases. G. A. DORNIN. *Trans. Am. Soc. Steel Treating* 13, 29-34(1928).—A discussion of the bad effects of oxides in steel and methods for their removal.

W. A. MUDGE

The tensile properties of iron-silicon alloys. TH. MEIERLING AND W. DENECKE. *Giesserei* 15, 381-4(1928).—The tensile properties of Fe-Si alloys contg. up to 5% Si, as given in the literature, are summarized. As no values could be found for alloys contg. up to 22.5% Si, results from old observations are given. In the present work an attempt is made to find the dependency of the tensile properties on the Si content in Fe-Si alloys with high Si. Melts of 100 kg. were prepd. in a graphite crucible from a special mild Fe and a "Si metal," the castings being made in green and dry sand molds. It was found that generally the bending strength decreases with increasing Si content, being max. at about 16% Si. Here Fe_3Si_2 also appears, accompanied with the formation of

eutectic graphite. The eutectic C content is max. in alloys contg. 16–17% Si. Castings made in green sand molds usually give smaller shrinkage than corresponding ones in dry sand. No differences in the tensile properties of castings made in the 2 types of molds could be detd. In the systems Fe–Si–P and Fe–Si–Cr the thermal effect of the Fe_3Si_2 formation is most evident around the eutectic compn. This is explained by a slight shifting of the atoms of the crystallites of the solid soln. and FeSi in the eutectic arrangement, making possible the formation of Fe_3Si_2 . J. BALOZIAN

Creep tests as made on Armco iron. H. J. TAPSELL. Eng. Research, Westminster, S.W.I., England. *Heat Treating and Forging* 14, 746–50 (1928).—Creep tests are made on Armco Fe (I) at 136° and 150° using a load of 25.7 tons/in.², and at 237°, 325° and 390° with loads of 20, 12 and 7 tons/in.², resp. These show a progressive decrease in plasticity and, under prolonged stress at temps. below the limiting creep values, it is replaced by apparent perfect plasticity. The new limit of proportionality, at all temps. and of all specimens, is much greater than the original value. The effect of temp. on I, strain-hardened at room temps., is studied at 150°, 240°, 290°, 340° and 390°. Under these conditions, an increase of temp. produces a further increase in the hardness, a long time being required for complete softening (if it occurs at all). Both strain and temp. hardening occur during a creep test. The removal of plasticity is accounted for by the strain and temp. hardening under const. stress, and at temps. below certain limiting values. It is shown that at 240° (also to be expected at higher temps.) the hardening of I is progressive throughout a creep test in which failure occurs. J. BALOZIAN

Armco ingot iron. REID L. KENYON. *Trans. Am. Soc. Steel Treating* 13, 240–60, 435–62 (1928).—A description of the material with chem. and phys. properties and microstructures. Data are given for hot- and cold-rolled bars and shapes, plates, sheets and wire. Tests included tension, compression, shearing, fatigue, impact and hardness. W. A. MUDGE

Procedure for simplified testing. G. D. JOHNSON. *Heat Treating and Forging* 14, 870–4 (1928).—Brief description of the spark test for differentiating between various types of steel, the shear and deep etching methods for detg. defects, and tests for decarburization and the effects of heat treatment are given. J. BALOZIAN

Expansion characteristics of low-expansion nickel steels. HOWARD SCOTT. *Trans. Am. Soc. Steel Treating* 13, 829–46 (1928).—Expansion curves on low expansion Ni steels and synthetic Fe–Ni alloys show the detrimental effect of Mn and Si. The advantage of cold working to reduce coeff. of expansion was confirmed. W. A. MUDGE

The significance of the proportional limit of steel at elevated temperatures. FRANCIS B. FOLEY. *Trans. Am. Soc. Steel Treating* 13, 813–22 (1928).—A discussion of methods for accurately detg. the proportional limit at elevated temps. W. A. MUDGE

The brittleness of metals used in aeronautical structures at high and low temperatures. M. CORELLI. Lab. du Génie Aéronautique, Rome, Italy. *Intern. Congress Testing Materials* 1927, I, 479–88.—Shock resistance is an important property of materials for use in aircraft. Since some of these materials are subjected to high temps. in use, or may be used in a cold atm., impact tests at various temps. were made. A Charpy machine was used, with specimens 1 cm. square. The specimens, either heated or cooled, were placed in the machine with a thermometer attached at one end by a Cu sheath packed with insulating cord. When the temp. reached the desired point, the thermometer was withdrawn and the test made at once. The results of a test made at temps. from –40 to 400° are tabulated. The impact resistance of a heat-treated Cr–Ni steel increased at the higher temp. to half its normal value. That of an annealed 0.6% C steel increased with rising temp. to 200°, but decreased at higher temp., and also at temp. below normal. Duralumin and electron showed better shock resistance as the temp. rose, but at low temp. showed little change. A special high-strength brass known as “delta metal” became very brittle at the higher temps., and showed little change at low temp. Expts. of this kind will be continued on other alloys. G. F. C.

Viscosity at high temperature, as applied to various metals and alloys. ANDRÉ MICHEL AND JEAN COURNOT. École Polytechnique, France. *Intern. Congress Testing Materials* 1927, I, 397–430.—When a specimen of steel is subjected to tension at elevated temp., several kinds of elongation occur, both elastic and permanent. A viscous deformation is said to occur when the rate of permanent elongation is const. or increasing. In practical use at a given temp., steel must resist the applied stress a very long time either without permanent deformation or with only slight deformation which does not increase. In the former case, the stress must be below the elastic limit for the given temp., and in the latter case below the limit of viscosity. The previous literature on elastic and plastic deformation under stress at high temp. is reviewed in considerable

detail. The great diversity of results is explained by differences in methods of testing. It is necessary to be able to define a practical limit of viscosity. This is a very complex problem because practical test results are indefinitely related to the conditions of service. Above the temp. of recrystn. the limit of viscosity may be nil or equal to the elastic limit; below that temp. the effect of coldworking is a factor in the problem. The definitions of this limit proposed by Pomp and Dahmen, and by Henry, resp., are discussed and their limitations shown. The former defined it as the stress producing an elongation of 0.001% per hr. between the 3rd and 6th hrs. of stressing; the latter gave a logarithmic formula applying only to steels between 500 and 800°. The logarithmic formula was not suitable for defining a practical viscosity limit. Measurements of the rate of deformation are first required in testing, and expts. with wires of various alloys at high temp. are described. The app. is illustrated, and the rates of flow at various loads and temps. are tabulated. For each temp., the rate of flow indicated by the straight portion of the elongation-time curve was plotted against the stress, and the curve extrapolated to intersect the axis of zero stress, this intercept being taken as the limit of viscosity. The breaking stress was also detd. in several tests. Various C and alloy steels, Cu, brass, Al-bronze, Ni, Al, duralumin, and alpac were tested. The practical viscosity limits of Al and duralumin, resp., increased a const. amt., independent of the temp., as the diam. of the test specimen was enlarged. The time required to reach the viscous state varied greatly with different alloys and at different temps.; it probably followed an exponential relation to the temp., being much shorter at higher temp. Although the results show approx. the relative viscosities of the alloys tested, they constitute only a simple contribution to the fundamental study required by the problem. Suggestions for further work are given in conclusion.

GEO. F. COMSTOCK

Testing of hardened steel. AXEL LUNDGREN. Govt. Testing Inst., Stockholm, Sweden. *Intern. Congress Testing Materials 1927*, I, 177-90.—Hardened tools are generally tested only by practical use, and a more systematic method was sought. A machine is described for repeated bending of 1.5 by 5 mm. bars of hardened steel under increasing loads, the results being plotted automatically as broken curves. The elastic and proportional limits and tensile strength were detd. with this machine; the Charpy machine was used to measure resistance to shock, and the Rockwell machine with diamond cone to measure hardness. Plain steels contg. 0.59 to 1.30% C were used for the expts.; specimens were heated for hardening in an elec. furnace, quenched in oil and tempered in oil up to 300° or in lead at higher temp. The results are shown in the form of curves. The high-C steels as rolled showed a cementite network, and when annealed the cementite was spheroidized. Both kinds were hardened and tested. When quenched from 765°, the eutectoid steel was weaker than the others at all tempering temps. below 300°. Raising the quenching temp. lowered the strength; the decrease was less after tempering at 200° than after tempering at 150°. Under nearly all conditions the eutectoid steel showed the lowest impact resistance, and the lower-C steel a better impact resistance than the others. The impact resistance was reduced as the quenching temp. was raised above 765°; the decrease was greater after tempering at 200° or 280° than at 150°, but at higher tempering temps. the effect of differences in quenching temp. decreased. The unannealed samples of the high-C steels showed greater hardness after quenching than the annealed samples. At about 55 Rockwell, all the steels showed about the same strength. At the highest hardness, the highest-C steel showed the best impact resistance, but at reduced hardness, the lowest-C steel was the toughest. Longer tempering at 150° or 200° gave reduced hardness but higher strength. Tempering a 1.24% C steel 60 min. at 150° gave greater strength and hardness than tempering 2 min. at 200°. After tempering at 300°, rapid cooling in water gave a lower bending strength than slow cooling, with the same hardness. Other interesting details of the results of tests are also given.

GEO. F. COMSTOCK

A note on the hardness and impact resistance of chromium-nickel steel. B. F. SHEPHERD. *Trans. Am. Soc. Steel Treating* 14, 67-71(1928).—Izod impact, hardness and tensile properties of Cr-Ni steels (S.A.E. 3250) with varying Ni and C contents are given. Higher C reduces impact resistance without increasing hardness. Tempering to 300° F. increases impact without materially affecting hardness.

W. A. MUNDAY

Hardening by reheating after cold working. M. A. GROSSMAN AND C. C. SNYDER. *Trans. Am. Soc. Steel Treating* 13, 201-15(1928).—The decrease in ductility in cold-worked steel, on heating at 600° F., originates in the amorphous metal produced by cold work. Metal grains deform by "block slip." Reheating at low temps. causes growth of thin, amorphous layers which obstruct deformation; reheating at higher temps. causes sufficient growth resultant ductility to be ineffective in obstructing slip. The brittle range (600° F.) observed in reheating quenched steels is due to non-ductile

transformed austenite in a matrix of tempered martensite; the non-ductile regions obstruct deformation of the softer matrix.

W. A. MUDGE

The transverse testing of cast iron. A. L. NORBURY. British Cast Iron Research Assn., Birmingham, England. *Intern. Congress Testing Materials* 1927, I, 385-8.—The transverse test is cheap and useful for cast Fe, but too many different sized bars are in use. The modulus of rupture formulas may be correct for a uniform material, but cast Fe bars are not homogeneous. Actually round bars give higher moduli than rectangular bars of similar cross section, and variations in length between 12 and 24 in. do not have as much effect as is called for by the formulas. For comparable results the square of the distance between supports divided by the modulus of section should be kept const. When bars cast in different sections are tested, lower moduli are obtained from white Fe and coarse gray Fe than from fine gray Fe in the intermediate sections. Most gray Fe bars are stronger at the outside than inside, but not if the outside is white. Gas cavities sometimes cause a weak zone at the outside or upper side of a cast bar. Methods of molding and pouring affect the properties of cast Fe bars by causing differences in soundness and in rate of cooling. The Brit. Eng. Standard Assn. are recommending 3 round bars of different sizes, from 0.875 in. to 2.2 in. in diam., each to be used in connection with castings of corresponding thickness.

GEO. F. COMSTOCK

The Neumann bands in ferrite. C. H. MATHEWSON AND G. H. EDMUNDS. Yale Univ., New Haven, Conn. *Am. Inst. Mining Met. Eng. Tech. Publication* No. 139, 22 pp. (1928).—The previous literature on the nature of Neumann bands is critically reviewed, the evidence presented being not incompatible with the view that they are mech. twins. They are readily formed in coarse-grained ferrite, which is brittle under shock. The mechanism of twinning in the body-centered cubic lattice is described and illustrated, as occurring around a diagonal of the unit cube, by photographs of a model. The same effect may be produced by translation, instead of rotation, of the atoms as is illustrated by diagrams. The Neumann bands are parallel to (211) planes, and a twin structure is obtained by sliding some of the atoms on these planes past others for a distance equal to $\frac{1}{2}$ the distance between planes. There are 9 twinning planes of form (211) in this lattice, and twinning around some of these are represented by stereographic projections, which are described. The work of Mugge in 1899 is reported, illustrating how the effect of twinning can be accomplished by sliding parallel planes past each other, and his measurements of the angles between Neumann lamellae and cleavage planes in soft Fe showed approx. the changes in the directions of the lattice planes produced by such movement. Neumann bands were produced by the authors in thin strips of coarse-grained ferrite contg. 3.78% Si, but not readily. Edgewise hammering between clamps was most effective in securing enough of the bands for x-ray analysis. By a study of the Laue pattern from this specimen, spots due to Neumann bands were identified that could not have come from planes in the original crystal. The cleavage planes of the crystal were found and their directions compared with the directions of the planes in twin position in Neumann bands. The relations of these various planes are discussed, but no conclusions are expressed.

J. BALOZIAN

The conditions required for formation of cementite. G. CHARPY AND P. PINGAULT. *Compt. rend.* 187, 554-6 (1928).—Previous expts. are reviewed, showing that Fe could be carburized at 600° to 650° with the formation of a layer of cementite sepd. from the original metal by a narrow transition zone, and that cementite could decomp. at 700°. Pure electrolytic Fe filings, free from H, were carburized by cyanide or hydrocarbons, and the phys. properties were studied. The d. decreased gradually with absorption of C to a limit of 7.40 at 0°. The magnetic attraction of 1 g. of Fe filings decreased, on carburizing, from 7 g. to a const. value of about 4 g. The filings carburized to const. d. and magnetic attraction contained 6.75% C and left no trace of insol. C when dissolved in HNO₃. This product did not suffer any change in properties after gradual heating to 1000° during 10 hrs. Slight sepn. of graphite in previous expts. of this nature may be attributed to oxidation. Fine Fe wire was transformed entirely into cementite, with no trace of graphite, after heating to 850° in cyanide. Pyrometer protection tubes of Fe 1 mm. thick from cementation furnaces were also found to be completely transformed into cementite. Carburization of solid Fe below 1000° tends therefore to form cementite, and the distribution of the C beneath the surface is detd. only by the rate of soln. and diffusion of cementite in solid Fe.

X-rays and the constituents of stainless steel. EDGAR C. BAIN. *Trans. Am. Soc. Steel Treating* 14, 27-50(1928).—One steel was used contg. C 0.77, Ni 0.24 and Cr 17.40%. Resistance to corrosion and hardness resulting from heat treatment depend upon carbide behavior. W. A. MUDGE

Furnace for treating stainless cutlery. GREGORY J. COMSTOCK. Firth Sterling Steel Co., McKeesport, Pa. *Heat Treating and Forging*, 14, 661-2(1928).—A furnace is described, which meets the necessary requirements and is capable of handling 5000-6000 blades in 8 hrs., for heat treating stainless steel cutlery. It is constructed on the semi-muffle principle and has a long, narrow, rectangular heating chamber, closed by doors raised with a treadle. Oil firing is used, the burner being movable horizontally to give even heating. Temps. are measured with a thermocouple introduced through the back of the chamber, and is provided with lights to aid in obtaining the temp. desired. J. BALOZIAN

A few steel cementations with special alloys containing manganese. JEAN COURNOT. *Compt. rend.* 187, 298-300(1928).—C. studies the cementation of soft, semi-hard and hard steel with: (a) ordinary Spiegel (15.42% Mn and 4.16% C), (b) ferromanganese (76.19% Mn and 6.52% C), (c) ferromangano-silico-aluminum (19.25% Mn, 20.64% Si and 10.34% Al). The best results are obtained when 2.5% NH_4Cl and 2.5% Al_2O_3 are mixed with the cementation agent. a gives the customary penetration structure; b gives a slow diffusion and produces an outside white constituent about 5/100 mm. thick after 4 hours at 1150°; this outside coat is very hard to attack; a high C content favors the formation of this coat; c gives an outside white layer, sharply outlined and no transition constituent. The hardness is about the same as in the case of C cementation but the results are more consistent. Corrosion tests in acids are also reported. J. BALOZIAN

Die-casting alloys of low melting point. T. F. RUSSELL, W. E. GOODRICH, W. CROSS and N. P. ALLEN. *Engineering* 126, 475-6(1928).—See C. A. 22, 4095. E. H.

The dependency of the breaking strength on the cross section of crude castings of German aluminum cast alloys (88 Al, 10% Zn, 2% Cu). WILLI CLAUS and JU-SZE TSAI. *Giesserei* 15, 342-3(1928).—Detn. of the breaking strengths of the cast "German" alloy (88% Al, 10% Zn, 2% Cu) for various cross sections shows that with increasing area of the section the breaking strength decreases. This is in agreement with the results of Souther (*Metallurgie* 1911, p. 719) for the 81.42% Al, 16.10% Zn, 2.48% Cu cast Al alloy. J. BALOZIAN

Stability of aluminum and magnesium casting alloys. A. J. LYON. U. S. A., Dayton, O. *Am. Inst. Mining Met. Eng. Tech. Pub.* No. 133, 15 pp.(1928).—Tension test specimens of various Al-base alloys and of 2 Mg-base alloys were cast in sand at carefully controlled temps., and tested for proportional limit, tensile strength, elongation, and Brinell hardness after aging at various temps. for different periods of time. The proportional limit of the Al alloy with 8% Cu was doubled by aging 2 years at room temp. The Al alloy contg. 5% Cu, 0.6% Fe, and 0.8% Si showed a similar increase in proportional limit, and a marked drop in ductility after atm. aging for 30 months, or aging at 300° F. for 20 hrs. Quenched duralumin also stiffened slowly at room temp., and should not be held too long before fabrication for use. Al-Cu-Mg alloys and the "Y" alloy contg. also Ni changed similarly when aged for a year, but reached a stable condition at 300° F. in 16 hrs. The properties of the Al-Si alloys did not change materially on aging, but their proportional limits were very low, being around 4000 lbs. per sq. in. as compared to 13000 lbs. per sq. in. for the aged alloys mentioned above. The Al-Zn alloys lost too much ductility on aging to be useful for air-craft. Their hardening is due to a phase-change rather than to a change in solid soly. of a constituent. These alloys are subject to weakness at high temp., and corrosion. The Mg alloy contg.

4.6% Al and 0.3% Mn did not harden or lose ductility on aging, but Mg alloys contg. Al and Zn increased in both strength and ductility. The properties of all these alloys aged different times are tabulated in detail. GEO. F. COMSTOCK

The constitution of the alloys of aluminum with copper, silicon, and iron. A. G. C. GWYER, H. W. L. PHILLIPS AND L. MANN. British Al Co., Ltd., Warrington, England. *J. Inst. Metals* (advance copy) No. 468, 52 pp. (1928).—Alloys of Al contg. up to 40% Cu, 20% Si, or 10% Fe, or combinations of 2 or 3 of these elements, were studied in regard to constitution and microstructure as ordinarily prepd. rather than under true equil. conditions. Previous work on the binary and ternary systems is reviewed. The soly. of Cu in Al was found to be over 5% at the eutectic temp. and under 0.5% at room temp. The soly. of Si in Al was found to be 0.35% at 450° and 0.15% at 300°. The ternary system Al-Si-CuAl₂ was simple at the Al corner, with not over 0.25% solid soly. of Cu or Si at room temp., and a eutectic contg. 26% Cu and 6.5% Si at 525°. CuAl₂ is etched deep brown by NaOH soln. while FeAl₃ is etched blue-green, and the needle or "N" constituent due to Fe is etched bronze. "N" is formed by a peritectic reaction at 590° between FeAl₃ and liquid, but this reaction was seldom complete. The FeAl₃ was often protected by a sheath of Al or of "N" constituent. The latter usually formed on other crystals rather than from its own nuclei. A ternary eutectic is formed at 540° in the Al-Cu-Fe system, and contains 32.5% Cu and 0.3% Fe, the components being Al, CuAl₂, and "N" constituent. A model of the quaternary system was constructed in the form of a tetrahedron and sections through it are illustrated and discussed. No new quaternary constituent was found within the range of compn. studied. The "X" of the Al-Si-Fe system and the "N" of the Al-Cu-Fe system were end members of a continuous series of solid solns., and in the quaternary system this was called "X." A quaternary eutectic freezes at 520° and contains 26% Cu, 6.5% Si, and 0.5% Fe, the components being Al, Si, CuAl₂, and "X." Numerous sectional diagrams are explained, and typical microstructures illustrated and described. Complete structural equil. was seldom attained, on account of the slowness of reactions and the formation of protective sheaths around reacting constituents. The structure of com. Al alloys is discussed; Fe in them generally occurs as "X," Cu as CuAl₂ and Si as the element or in "X." Diagrams are presented to show how the occurrence of these constituents is related to differences in purity of com. Al alloys. The appearance and etching characteristics of the various constituents are described. GEO. F. COMSTOCK

The reversed block liquation in aluminum bronze (4.5% Al, 95.5% Cu). WILLI CAUS AND FRITZ GOEDERITZ. *Giesserei* 15, 398 (1928).—A study of reversed block liquation in the 95.5% Cu, 4.5% Al alloy, the castings being made in cast Fe, and green and dry sand molds. If the alloy showed liquation, then differences in the chem. compn. of the exterior and interior of the castings, and of its top, middle and bottom, must be apparent. Duplicate analyses give the Cu content of the castings, independent of the type of mold used, as 95.5% and the Al as 4.4%. Thus, reversed block liquation is not shown by this Al bronze, apparently because of the small solidification interval of this alloy. J. BALOZIAN

Smoothing and etching cupronickel, bronze, brass and steel. H. B. PULSIFER. Ferry Cap & Set Screw Co., Cleveland, O. *Am. Inst. Mining Met. Eng. Tech. Publication* No. 137, 18 pp. (1928).—A rapid method of prepn. of metallographic specimens is described, involving hand-rubbing on emery papers first, and finally on chamois-skin carrying tripoli powder. Etching is relied on to remove the final scratches. CrO₂ added to HNO₃ for etching gave good results with this method. Sometimes repolishing and re-etching after a preliminary etch were advantageous. A large no. of photomicrographs are presented to show P.'s results with Ni and Cu alloys and steels. The specimens were claimed to have been prepd. in 2 min. each. CrO₂ was useful in acid FeCl₃ for etching bronze. The addn. of 5% Be raised the Brinell hardness of cupronickel from 126 to 302. It was difficult to remove the final scratches from steel by etching, and a final polish with rouge, Al₂O₃ or MgO was often worth while, especially after a preliminary etch. An active etching reagent for steel was 0.5 cc. H₂SO₄ in 100 cc. satd. KClO₃ soln., but it was liable to give promiscuous corrosion. Steel wire contg. 0.12% C when quenched from 1500° F. was brittle because the hardening constituents were not thoroughly diffused at that temp. Light etching with HCl and high magnification served to reveal the cause of brittleness. The segregated martensitic nodules reverted to cementite on annealing. GEO. F. COMSTOCK

The constitution of the copper-silicon system. CYRIL S. SMITH. Am. Brass Co., Waterbury, Conn. *Am. Inst. Mining Met. Eng. Tech. Publication* No. 142, 25 pp. (1928).—The Cu-Si equil. diagrams proposed by Rudolphi, Sanfourche, Corson, and Matuyama are shown and criticized, the last one more favorably than the others. The

exptl. alloys examd. by S. were made of electrolytic Cu and Si contg. 0.44% Fe. The compn. was checked in most cases by a detn. of Cu only. The methods of chem. and thermal analyses are given, the chromel-alumel thermocouple being protected from contact with the melt by a C sheath 1/16 in. thick. To det. the compn. ranges over which the various phases existed, the structures of annealed and quenched samples were studied with the microscope. Oxidation of Si from the high-Si samples during the annealing was worse in the CO-N₂ atm. obtained by the use of charcoal than in illuminating gas, but allowance was made by reducing the time of annealing below 4 hrs. and discarding the outer layer of the samples. A new equil. diagram is given, with the exptl. points shown in detail, up to 20% Si. The limits of the α phase were given in a previous paper (*C. A.* 22, 3873). β is formed at 852° by a peritectic reaction of α with liquid contg. 7.7% Si. It may contain 6.8–8.4% Si, but at 782° with 7.75% Si it decomposes into the α plus Δ eutectoid. The decompn. was not prevented by the most rapid quenching. At 824° satd. β reacts with liquid to form Δ contg. 8.60% Si, and the Δ phase extends to 9.7% Si at 820°. At 710° Δ with 8.95% Si decomposes into the γ plus epsilon eutectoid. This decompn. could be retarded by quenching, giving martensitic or sorbitic structures, γ contg. 8.35% Si is formed at 726° by a reaction between Δ and α , and may contain over 9% Si at lower temp. Epsilon, causing a max. in the liquidus at 12.3% Si and 859°, forms eutectics with Δ at 820° and 9.9% Si, and with 802° and 16% Si. It may contain from 11.2 to 13% Si, and changes, at 620° on the γ side and at 558° on the Si side, to another form called epsilon prime with slight pptn. of Si. These alloys did not disintegrate when exposed to air. The soly. of Cu in Si was detd. to be less than 4.4%, if any. The existence of definite compds. was not indicated, and all the phases were considered as solid solns. The microstructures are illustrated by 30 excellent photomicrographs, which are fully discussed. The β eutectoid was well etched with a satd. soln. of K₂Cr₂O₇ in 10% H₂SO₄ with the addn. of 2% of a satd. soln. of NaCl. The Δ alloys were etched very well with a 20% soln. of FeCl₃ in 1–4 HCl. Both solns. served well for the γ alloys. Epsilon was well etched by atm. tarnishing, or by FeCl₃ which developed striae in epsilon grains but not in epsilon prime. G. F. C.

The chemical destruction of cast iron. W. DENCKE. *Giesserei* 15, 307–12 (1928).—Corrosion of cast Fe (I) is ascribed to chem. causes, local elements and erosion. To study the dissolving action of alkalis and acids on I (contg. besides graphite, less than 1% Si, Mn, P, S and perhaps Cu or Ni) specimens are suspended in: (1) molten KOH and NaOH for 18 and 20 hrs. and (2) 10% HCl for 46 hrs. In the molten alkalis, specimens contg. Ni show the least, and those with Si, P and S the greatest, soly., while no decidedly unfavorable influence of Mn could be detected. In the acids, the Si-rich specimens behave the best and those contg. Ni, P and S the poorest, while Mn acts favorably. The suspension of I contg. Cu in 10% HCl for 24 and 43 hrs. at room temps. shows that stability toward this acid is increased by Cu (optimum at 0.5%). The effect of Si on the soly. of I contg. varying amts. of Si up to 17% is detd. in boiling 15% and 10% H₂SO₄, and 5% HCl. The superiority of I with high Si content is clearly seen. The Guertler-Tammann Fe-Si diagram as modified by Körber, and the solidification fields of the Fe-Si-C alloys are discussed. The disadvantages of high Si content and the importance of the graphite distribution on the corrosion of I are briefly stressed. J. B.

The corrosion of iron. WILHELM VAN WÜLLEN SCHOLTEN. *Gas u. Wasserfach* 71, 872–80 (1928).—The electrolytic theory of corrosion is reviewed in a comprehensive manner and an extensive and up-to-date bibliography given. R. W. RYAN

The corrosion of metals. WM. M. GUERTLER. *Trans. Am. Soc. Steel Treating* 13, 759–94 (1928).—The first Edward DeMille Campbell lecture. All com., acid-resisting alloys must be the group of elements Fe, Cu and Ni. Addnl. elements should be those which will enter into solid soln. W. A. MUDON

Durability tests of nickel chrome resistor materials. F. E. BASH, Driver-Harris Co., Morristown, N. J., and J. W. HARSCH, Leeds & Northrup Co., Phila., Pa. *Intern. Congress Testing Materials* 1927, I, 463–78.—The service of elec. heating elements depends on the quality of the materials as well as on the design. The Ni-Cr alloys oxidize readily, but the oxide constitutes an efficient protective coating. Failure of such heating elements occurs by development of a hot spot where the coating has cracked off, and the life is much shorter in intermittent than in continuous heating. The variables affecting a life test are temp., size and condition of wire, voltage, atm., and mounting. Vertical suspension was the best mounting method, and draughts of air must be avoided. Some previous methods of test are reviewed; heating from an external source is not desirable in testing. Tests may be made at const. temp., or at const. voltage, and both intermittent and continuous tests are desirable. The lengths of both heating and cooling periods have important influences on the results. Changes in resistance, in

temp., and in length and ductility of the sample after testing should be noted. The trial specifications adopted by a comm. of the Am. Soc. Testing Materials are given in detail. Tests made under these specifications are being conducted in 10 labs. to evolve a standard method of testing. Specimens 12 in. long are suspended vertically from a binding post, the bottom contact being in a Hg cup. Temps. are measured with a disappearing-filament optical pyrometer having a short-focus objective lens. A standard procedure, and records, are also given in detail. Before testing, the uniformity of a given coil of wire should be established. The salts of alkali metals injure hot Ni-Cr wires, and must be avoided. The results of tests so far made with this method are encouraging.

GEO. F. COMSTOCK

The corrosion-resistant ferrous alloys. JOHN A. MATHEWS. *Intern. Congress Testing Materials 1927*, I, 103-10.—Non-corrosive steels are an important new development and their value to industry is not widely realized. Austenitic Cr-Ni steels are 2 or 3 times as strong as ordinary metals above 600°. Non-corrosive steels that harden by quenching are Cr alloys; those with less than 0.12% C and 12 to 14% Cr are known as "Stainless Iron," and when normalized have 140,000 lbs. per sq. in. yield point, 160,000 lbs. per sq. in. tensile strength, 12% elongation in 2 in., 35% reduction of area, and 300 Brinell hardness. When heat-treated the properties are slightly improved. This steel is unaffected by atm. or salt-water corrosion, HNO₃, or alkalis. "Stainless Steel" with 0.3 to 0.4% C must be hardened and polished for max. corrosion resistance. Unhardenable non-corrosive steels may be Ni, Cr, or Cr-Ni alloys. Those contg. 25 to 35% Ni have been longest known, and resist HCl better than Cr steels. Those contg. 16 to 30% Cr are soft and ductile, but weak in shock resistance. Those contg. high Ni and Cr, with 2 to 3% Si, originated by C. M. Johnson, are very interesting and resistant. At 700° where the strength of ordinary steel is negligible, austenitic Cr-Ni steel may show 65,000 lbs. per sq. in. tensile strength. Full cooperation between the user and maker is very important for the most useful development of these alloys. In discussion, E. C. Bain and M. A. Grossman showed that steels with 17 to 25% Cr are non-hardenable because they always remain as α Fe; they are readily fabricated, cheaper, but less rust-resistant than the austenitic steels, which harden by cold-work. A. Michel described the Parkerizing method of protecting from rust by coating with a penetrating layer of complex phosphates, and its effects.

GEO. F. COMSTOCK

Arc welding. D. C. COOPER. *Facts about Sugar* 23, 977 (1924).—It is suggested that internal-combustion engines driving welding generators be arranged to be idle when the load is removed and maintain the working speed only when the arc is struck. The welding arc should be maintained about $\frac{1}{8}$ in. long. A table is given indicating the chem. and phys. characteristics of mild steel welding metal before and after welding. Important work should not be undertaken except by skillful operators.

M. J. P.

The effect of coal segregation, mixing and heating upon the quality of metallurgical coke (MARQUARD) 21. Occurrences, metallurgy and uses of Hg (EARDLEY-WILMOT) 8. Production of Cu castings having high electrical conductivity (MASING, HAASE) 4. Furnaces suitable for heating metal sheets in annealing boxes, etc. (U. S. pat. 1,688,393) 1. Plant for treating graphite and other ores (Fr. pat. 638,088) 18. Regenerative channel oven for heating steel billets (U. S. pat. 1,687,774) 19.

KAUTNY: *Leitfaden für Acetylschweisser*. 9th ed. Halle: Carl Marhold. 252 pp.; M. 4. Reviewed in *Chimie et industrie* 20, 600 (1928).

Apparatus for froth-flotation concentration of ores. FREDERICK SWINNEY. U. S. 1,688,998, Oct. 23.

Flotation separation of mixed sulfides in ores. KOJIRO KAWAMURA (one-half to Yoshimatsu Yokoyama). U. S. 1,688,277, Oct. 16. Ores such as those contg. sulfides of Cu, Fe and Zn are treated with crude com. anhyd. chromic acid together with alkali to neutralize any H₂SO₄ present in the crude chromic acid. This addn. to the ore pulp serves to inhibit flotation of Cu and Fe sulfides without affecting ZnS, when flotation is effected with the usual flotation agents.

Separating minerals or other materials by flotation. COOPER SHAPLEY. U. S. 1,689,693, Oct. 30. Finely divided particles such as those of fluorite, rutile or corundum are contacted with a soap soln. which does not react chemically with the particles and the particles are then brought to the surface of a body of water free from any reagent which would decomp. the soap.

Flotation oil. ROYER LUCKENBACH. U. S. 1,688,975, Oct. 23. An oil for mineral flotation comprises a heavy petroleum residuum, a petroleum diluent such as a light petroleum distillate and a frother contg. cotton-seed foots, pine creosote and a soap.

Reduction of ores and conversion of hydrocarbons. WM. H. SMITH. Fr. 638,251, July 26, 1927. Metallic oxides, particularly ores, are reduced by adding heavy hydrocarbons which are converted into light hydrocarbons, the oxides acting as catalysts. The process can be made continuous.

Direct reduction of iron ores. TOUSSAINT LEVOZ (to Naamlooze Vennootschappij Handelsmaatschappij Feriron). U. S. 1,689,734, Oct. 30. A charge comprising Fe ore, reducing carbon, oxides of alloy metals such as Si and Mn, and a low m.p. aluminous flux is subjected to a comparatively low temp. (suitably about 1700°) to produce a low-C ferro alloy and a covering slag; the temp. is raised to reduce the C content of the alloy by interaction of the C with the oxidized Al in the slag, and components other than Fe of the alloy are then reduced by use of an oxidizing agent such as Fe oxide. An app. is described.

Removing arsenic from ores, etc. NORDDEUTSCHE AFFINERIE. Brit. 286,285, March 3, 1927. As is removed from ores and metallurgical products such as mats, speiss and Cu-As compds. by the addn. of S-bearing material and carbonaceous fuel and by the combustion of the mixt. in a restricted supply of air without the application of external heat. A superposed hearth furnace with rabble arms is preferably used, but a rotary drum furnace may be employed.

Briquetting coal, ores or other materials. R. LESSING. Brit. 286,336, Nov. 3, 1926. For briquetting coal, ores, metal scrap, etc., or for treating "rod metal," the material is coated with coal tar or other liquid contg. pitchy and oily fractions. An oil solvent contg. little or no aromatic constituents such as a petroleum distillate is then used to ext. the oily portion and ppt. the pitch in a homogeneous coating on the solid particles to be briquetted. Extn. of the tar oil is facilitated by addn. of H₂SO₄, an acid soln. of Fe sulfate or chloride or spent liquor from pickling steel. Numerous details and modifications of the process are given.

Core material for use in metal founding. WILLIAM B. RUNYAN (to Dayton Malleable Iron Co.). U. S. 1,688,661, Oct. 23. Core material such as sand is treated with definitely proportioned quantities of oil and water and the materials are intimately mixed. An app. is described.

Magnet cores. FELTEN & GUILLEAUME CARLSWERK A.-G. Brit. 286,202, Feb. 26, 1927. Magnet cores for Pupin coils, etc., are formed from ball-shaped Fe particles having a diam. of less than 10 μ which are coated with an insulating layer such as cellulose acetate and then subjected to pressure less than the elastic limit of the Fe powder. Powder formed by reduction of Fe carbonyl with H is suitable. Cf. C. A. 22, 2350.

Magnetic cores. I. G. FARBENIND. A.-G. Brit. 286,167, Sept. 5, 1927. In making metallic powders for compression into cores for electromagnets, Pupin coils, etc., by decomp. the corresponding metal carbonyl, instead of treating the resulting powders in an inert atm., as described in Brit. 269,770 (C. A. 22, 1286) the powder is heat treated in a reducing atm. and is then ground (preferably in a ball mill), generally in the absence of O. An example is given of the prepn. of Fe powder from Fe carbonyl.

Separable hot top for ingot molds. JOHN E. PERRY (to Valley Mould & Iron Corp.). U. S. 1,689,174, Oct. 23. Structural features.

Hot top for ingot molds. WILLIAM H. RAMAGE (to Valley Mould & Iron Corp.). U. S. 1,689,175, Oct. 23.

Magnetic control of ingots and steel bars. FORGES ET ACIÉRIES DE LA BERARDIÈRE BÉDEL ET C^{ie}. Fr. 636,133, Oct. 8, 1926. Irregularities in ingots or steel bars are detected by placing the ingot in a magnetic field created by a solenoid and measuring either the induction produced or the residual magnetism.

Molds for casting metals. CLIFTON D. PETTIS. U. S. 1,688,350, Oct. 23. A molding surface such as a "permanent" mold is treated with a mixt. of fire clay with silica and Na silicate and then treated with an oil, e. g., crude oil or tar which serves to leave a graphitic pore-filling residue.

Device for supplying stereotype metal or other molten metals to a movable casting box. ISIDOR TORNBERG (to Wood Newspaper Machinery Corp.). U. S. 1,689,698, Oct. 30.

Stationary apparatus for filling molds in casting metals. N. LITTELL. Brit. 286,109, April 4, 1927.

Joining metals by casting. W. SMITH. Brit. 285,995, Nov. 25, 1926. Before casting molten metal to be joined with pieces of solid metal the latter is amalgamated at the surface to be joined or an amalgamated metal strip is placed adjacent the surface. The method is suitable for Pb, Cu and Al. Fe and steel may be galvanized before amalgamating and castings to receive bearing metal may be similarly treated.

Casting ferrous metals. PORTER W. SHIMER and EDWARD B. SHIMER. U. S.

1,687,799, Oct. 16. A chaplet for use in ferro metal founding is provided with a coating of a ferro-alloy such as spiegeleisen and ferro-P which melts at or below the casting temp.

Malleable iron castings. HARRY A. SCHWARTZ (to National Malleable and Steel Castings Co.). U. S. 1,688,438, Oct. 23. See Brit. 282,671 (C. A. 22, 3622).

Apparatus for centrifugal casting of pipes or like metal articles. J. HOLTHAUS (to International Delavaud Mfg. Corp., Ltd.). Brit. 285,821, Feb. 21, 1927.

Forming cast iron pipe or like articles. JAMES R. MCWANE. U. S. 1,688,727-8, Oct. 23. Mech. features.

Centrifugal casting of cast iron cylinders for internal-combustion engines, etc. NEWTON, CHAMBERS & Co., LTD., and J. E. HURST. Brit. 285,721, July 15, 1927. The Si content of the metal is adjusted and the casting is rapidly cooled from a temp. almost immediately below its solidification point (by means of an air blast which may be moistened) to obtain a sorbitic structure in order to render the article more resistant to wear, impact and vol. changes on heating and to increase its tensile strength. The proportion in Si is low and depends on the av. thickness of the casting and on the thermal cond. and temp. of the mold material. Examples are given with Si varying from 0.5% to 2.25%.

Plate mill for rolling hot metal. JOHN B. TYTUS (to American Rolling Mill Co.). U. S. 1,688,252, Oct. 16.

Apparatus for rolling metal tubes from hollow blocks. M. ROECKNER. Brit. 285,894-5-6-7, Feb. 25, 1927.

Finishing metal bars or other rolled metal shapes. SAMUEL G. WORTON. U. S. 1,689,544, Oct. 30. Articles such as bars are subjected to grinding after completion of the rolling operation and while still at a temp. approx. that at which the rolling is completed.

Thermal treatment of metals. WM. EWART WATKINS. Fr. 638,206, July 25, 1927. Metals which are passed through a furnace in the form of a band, e. g., for annealing, hang freely between rollers one at each end of the furnace.

Refining lead, etc. AMERICAN SMELTING AND REFINING CO. Brit. 285,630, Jan. 21, 1927. A molten metal such as Pb is treated for the removal of impurities such as Zn by introducing a gaseous reagent such as Cl in a reaction chamber through which the molten metal is repeatedly passed. An app. is described in which dross of $ZnCl_2$ may be confined by an iron ring dipping into Pb, whence the dross may be removed by skimming.

Recovering copper, zinc, etc., from liquors containing them. C. F. SCHANTZ. Brit. 285,662, March 12, 1927. Solns. contg. Cu and Zn in the form of chlorides or mixed chlorides and sulfates, such as solns. obtained by lixiviation of pyrites roasted under chlorination, are tested for Cu, Cl and free acid and there is added to the liquor such a quantity of H_2SO_4 as will suffice for converting to HCl the Cl present (other than that already in the form of free acid) and the Cl in the form of $CuCl_2$. There are also added a quantity of finely divided Cu slightly in excess of the Cu content, and a quantity of Cu_2O (or CuO and Cu) sufficient to convert into Cu_2Cl_2 the total Cl content less the quantity of Cl combined with the Cu content reckoned as $CuCl_2$ so that all the Cu and Cl are pptd. as Cu_2Cl_2 , Ag and Au are pptd. as metals and Pb as sulfate, while a sulfate liquor contg. Zn, Na, Fe, As, Ni and Co remains. Numerous details for the recovery of values from this soln. are given.

Aluminum. ZAIDAN HOJIN RIKAGAKU KENKYUJO. Fr. 637,879, July 18, 1927. Pure Al is obtained from Al contg. one or more impurities of Si, Fe, ferrosilicon and oxides of Fe, by Cl or gaseous HCl at a temp. above 200° with or without one or more reducing agents.

Zinc dust. FRANKLIN P. LANNON, JR. (to American Smelting & Refining Co.) U. S. 1,688,426, Oct. 23. Zinc fumes are circulated vigorously and rapidly quickly to cool them to a point considerably below the vaporizing temp. so that the Zn particles are solidified as they are incipiently condensed and formed. An app. is described.

Porous metallic bodies. GENERAL MOTORS RESEARCH CORP. Fr. 636,124, June 17, 1927. Parts of machinery such as bearings are made of porous metallic substances composed of metals which do not alloy even partially so that they will absorb lubricant. An example given contains Cu 68, Pb 25, graphite 5 and Sn phosphide 2 parts. The powd. constituents are mixed and heated with a volatile substance such as salicylic acid. Cf. C. A. 22, 4452.

Open-hearth furnace and tuyère construction. RICHARD H. STRYVENA (to Bethlehem Steel Co.). U. S. 1,689,563, Oct. 30.

Cupola furnace. L. F. C. Girardet. Brit. 286,295, March 4, 1927. The fore-

hearth of a cupola furnace is a plate or table which forms a parallel motion connecting-rod between 2 similar crank arms, so that the fore-hearth can be moved in a gyratory manner to mix the metal.

Fusion furnace for metals or alloys. E. CHABOCHE ET CIE. Fr. 637,979, Nov. 29, 1926.

Rotatable metallurgical furnace suitable for producing wrought iron. ARTHUR J. BRIGGS (to Onondaga Steel Co.). U. S. 1,687,925, Oct. 16.

Blast furnaces. FRIED. KRUPP AKTIENGESSELLSCHAFT FRIEDRICH ALFRED HÜTTE. Fr. 638,264, July 26, 1927. In blast furnaces wherein part of the gas from the mouth of the furnace is reused, the charge of coke is calcd. exactly, the blast is introduced at the highest possible temp., and modifications are compensated for by adjusting the amt. of gas to be used from the mouth.

Blast furnace for the continuous treatment of ores, etc., with cooled hearth. GOTTFRIED VERVUERT and GEORGE RIEBER. Fr. 637,998, May 5, 1927.

Blast pipes for blast furnaces. CLAUDIUS DUCHASSIN. Fr. 636,426, June 22, 1927.

Apparatus for tapping blast furnaces. EDGAR E. BROSIUS. U. S. 1,688,327, Oct. 23.

Furnace for heating steel blanks for cutter bits, etc. HARRY C. JOHANSEN (to Sullivan Machinery Co.). U. S. 1,688,814, Oct. 23.

Furnace for annealing brass, copper, etc. ALBERT N. OTIS and LOUIS F. WOOLSTON (to General Electric Co.). U. S. 1,688,745, Oct. 23. A preheating chamber is provided with a vertically movable device acting as a common support for a cold charge being preheated and a hot charge being cooled.

Induction electric melting furnace construction. JAMES R. WYATT (to Ajax Metal Co.). U. S. 1,688,220, Oct. 16.

Reversing furnace construction. WALTER DE FRIES (to Blaw-Knox Co.). U. S. 1,687,710, Oct. 16. A furnace is described which is suitable for refining steel.

System of fuel and air supply, etc., for operating metallurgical open-hearth furnaces. FRANK B. MCKUNE (to Open-Hearth Combustion Co.). U. S. 1,687,682, Oct. 16.

Checkerwork for regenerative chambers. FRANK R. MCGEE. U. S. 1,689,041, Oct. 23. Structural features. U. S. 1,689,042 relates to a hot-blast stove construction.

Checkerwork construction for regenerators. ALBERT E. PETERSON. U. S. 1,687,786, Oct. 16.

Gray iron. EMIL SCHÜZ (to the firm of Meier & Weickelt). U. S. 1,689,456, Oct. 30. Fe having a high Si content is melted to form gray Fe; the Si content is chosen in proportion with the chosen rate of cooling, and may be about 3.5% for rapid cooling in an Fe mold.

Steel. H. J. VAN ROYEN. Brit. 285,814, Feb. 21, 1927. In producing steel resistant to deformation by cold and aging, the steel is deformed during the molding or working process at a temp. below the A^1 point and then annealed by heating to a temp. above the A^1 but below the A^1 point and cooled in still air. The process may be repeated.

Rolled steel articles. SAMUEL G. WORTON. U. S. 1,689,512, Oct. 30. In order to remove surface defects from rolled steel articles such as blooms and billets before final rolling, the side surfaces of the articles having these defects are ground off while the articles are heated to approx. a rolling temp.

Hardening steel. SOCIÉTÉ AUBERT ET DUVAL FRÈRES. Fr. 638,322, July 27, 1927. During the hardening of steel by N parts are protected against the N by a coating of Sn or Sn alloy which may be made resistant to the temp. used by a layer of Na_2SiO_3 and powd. Al.

Alloy steel. CHARLES MCKNIGHT, JR. (to International Nickel Co.). U. S. 1,689,043, Oct. 23. In order to stabilize the solidification of an alloy steel casting formed from scrap initially having a high Si content, the metal is melted under oxidizing conditions until the Si content is below a crit. point, not exceeding 0.1%, and the metal is then subjected to reducing conditions and alloying materials are added.

Steel alloy. FRIED. KRUPP AKTIENGESSELLSCHAFT. Fr. 638,263, July 26, 1927. An alloy of steel resistant to heat and chem. action contains Cr 15-25, Ni 15 to 25 and C less than 0.2%. Typical alloys are Cr 25, Ni 20, C 0.1% and Cr 20, Ni 25 and C 0.1%. Cf. C. A. 22, 4455.

Alloys. THOMAS DANIEL KELLY. Fr. 638,455, July 29, 1927. See Brit. 264,414 (C. A. 22, 55).

Alloys. THOMAS DANIEL KELLY. Fr. 638,456, July 29, 1927. See Brit. 277,170 (C. A. 22, 2351).

Alloys. THOMAS DANIEL KELLY. Fr. 638,457, July 29, 1927. See Brit. 270,553 (C. A. 22, 1569).

Alloy. ELECTROLYTIC ZINC Co. OF AUSTRALIA, LTD. (S. W. Ross; R. T. D. Williams, R. S. Russell, inventors). Australia 8993, Aug. 22, 1927. A bearing alloy contains Cd 95-97, Cu 3-5, with or without up to 0.5% of Mg.

Bearing alloy. CHRISTOPHER H. BIERBAUM (to Lumen Bearing Co.). U. S. 1,687,924, Oct. 16. An alloy of Cu 84.5, Sn 10.5 and Ni 5% is cast in the absence of Zn against a chill so that the α -crystal is not hardened but left soft and a large amt. of hard delta crystal is formed upon the chilled surfaces; a wide range of hardness is provided between the hardest delta crystal and the softest α -crystal.

Alloys for turbine blades, etc. HERAEUS VACUUMSCHMELZE A.-G. AND W. ROHN. Brit. 286,367, Dec. 3, 1926. Alloys are formed contg. Cr 10-40, Ni 40-85 and Fe 1-40%, practically free from C, and may contain also W up to 15%, Mo up to 12%, Al up to 6% and Co 2-20%. The alloys may be made by the vacuum smelting process.

Alloy suitable for use in submarine cables, etc. WILLOUGHBY S. SMITH, HENRY J. GARNETT and JOHN A. HOLDEN. U. S. 1,688,247, Oct. 16. An alloy formed largely of Ni contains also Fe 6-17 and Al 1-5% and 1-5% of a fourth metal for increasing the elec. resistance such as Cr, Mo, W, V or Si.

Apparatus for magnetic tests of alloys, etc. C. KINSLEY (to Federated Engineers Development Corp.). Brit. 285,860, Feb. 23, 1927.

Refining metals and alloys. FRIEDRICH WILHELM CORSALLI. Fr. 638,486, June 24, 1927. App is described for obtaining a homogeneous mixt. of molten metal or alloy after its exit from the cupola furnace, after the addn. if necessary of refining or reducing substances such as C, Al or Na_2CO_3 .

Increasing the hardness of metals and alloys. SIEMENS & HALSKE AKTIEN-GESELLSCHAFT. Fr. 636,519, June 24, 1927. Metals and their alloys, particularly Ni, Co and Pb, have their hardness increased by alloying them with small quantities of Be. Other elements such as Sn, Zn, Sb, Al, Cd, Fe, C, Si or P may also be added. An addn., e. g., of about 0.2% of Be to Pb increases the hardness by about 100%. An addn. of 3% of Be to Co gives an alloy of about 270 Brinell. Ni contg. 13.4% Be will scratch glass.

Aluminum alloys. T. S. FULLER (to British Thomson-Houston Co., Ltd.). Brit. 285,908, Feb. 25, 1927. An alloy suitable for use in elec. motor rotors comprises Al with Mn 4-10 and Zn 2-8%.

Aluminum alloys. JEAN HANCO. Fr. 638,159, July 23, 1927. In making light Al alloys of high resistance a mixt. of 2 parts of BaCl_2 and 1 of crystd. KCl finely ground is added to the melted alloys. The mixt. corresponds to about 5% of the weight of the melt. If the alloy contains 5% or more of Si, the KCl is replaced by MnCl_2 or SnCl_2 , or a mixt. of CaCl_2 and MnCl_2 or a mixt. of metallic Sn and SnCl_2 is used.

Iron alloy. PERCY A. E. ARMSTRONG. U. S. 1,687,486, Oct. 16. An alloy resistant to scaling at elevated temps. contains Cr 9, C 0.50, Si 3.5 and Ta 3%; the remainder is principally Fe. This alloy is suitable for valves of internal-combustion engines.

Zirconium-treated iron-chromium alloy. FREDERICK M. BECKETT (to Electro Metallurgical Co.). U. S. 1,689,276, Oct. 30. Wrought articles such as tubing are formed of a ferrous alloy contg. Zr 0.008% or somewhat more and Cr 10-60%. This alloy has working properties superior to those of an alloy free from Zr but otherwise of similar compn.

Magnesium alloys. ZAV JEFFRIES and ROBERT S. ARCHER (to American Magnesium Corp.). U. S. 1,689,630, Oct. 30. In working Mg base alloys such as those contg. Al and Zn, Cd, Cu or Mn, the solid metal is subjected to heat treatment at a high temp. (suitably about 400-440°) for several hrs., below the melting temp. of the most fusible constituent of the alloy, to increase the plasticity of the alloy, and the latter is then subjected to mech. deformation.

Alloy of magnesium, aluminum and copper. JOHN A. GANN (to Dow Chemical Co.). U. S. 1,688,043, Oct. 16. An alloy which may be used for pistons of internal-combustion engines comprises Mg 90, Al 9 and Cu less than 1.5 parts. Cf. C. A. 22, 3624.

Closing the pores of metal layers deposited one upon another. NIKOLAUS MEURER (to Metallogen G.m.b.H.). U. S. 1,688,127, Oct. 16. A metal article which may be formed of iron is coated by spraying with another metal such as Zn and after this metal layer is applied it is successively treated with different substances such as BaCl_2 and a sol. sulfate which react together to form a ppt. which serves to close the pores of the metal. Addnl. layers of metal may also be applied, each of them being also subjected immediately to the pore-closing treatment.

Renewing worn surfaces of metal articles. E. H. JONES and S. WILLIAMS. Brit. 286,089, March 2, 1927. Shafts or other articles which have become worn are wound or covered with metal wire or strip which may be welded or brazed to the surface and hardened or machined.

Plating metal. WM. EWART WATKINS. Fr. 638,207, July 25, 1927. See Brit. 282,624 (C. A. 22, 3621).

Metal articles with irregular plated surfaces. EDMUND M. WISE (to Wadsworth Watch Case Co.). U. S. 1,689,810, Oct. 30. Watch case bows or other articles are formed of base metal shaped with substantially the surface form finally desired, are then coated, e. g., with Au or Ag, and subjected to a final shaping to bring out the surface irregularities desired.

Retort suitable for heat treating metal articles. EDWARD P. VAN STONE (to General Alloys Co.). U. S. 1,689,808, Oct. 30. Structural features.

Apparatus for removing carbon and gases from tantalum wire. MINER M. AUSTIN and CLARENCE W. BALKE (to Fansteel Products Co.). U. S. 1,688,481, Oct. 23.

Wire for uninsulated electric conductors. COMPAGNIE DE PRODUITS CHIMIQUES ET ELECTRO-METALLURGIQUES ALAIS, FROGES, ET CAMARGUE. Brit. 286,264, March 2, 1927. Light Al alloys such as Al-Cu, Al-Li, Al-Mg silicide, Al-Be or ternary or quaternary alloys of these metals with addns. of Ni, Cd or Mn are subjected to mech. and heat treatment, e. g., a billet of the alloy is first rolled or drawn to a diam. greater than that finally required and the coiled wire thus formed is tempered and then reheated for several hrs. at a temp. usually of 125–175° but which may be up to 250°, and the wire then cold-drawn to size and annealed at 125–250°.

Blowpipe apparatus for cutting metals by fusion. T. R. HANCOCK and J. CUTHBERTSON. Brit. 285,959–60, Nov. 22, 1926. Structural features.

Annealing metal bonds. MANSFELD AKTIENGESSELLSCHAFT FÜR BERGBAU UND HÜTTENBETRIEB and OTTO BUSSE. Fr. 635,876, June 11, 1927. The bands are passed through a furnace contg. a layer of asbestos or the like between the lower surface of the band and the base of the furnace.

Welding rod. FREDERICK M. BECKET (to Oxweld Acetylene Co.). U. S. 1,689,577, Oct. 30. See Can. 275,681 (C. A. 22, 1131).

Electrodes for arc welding. ALLOY WELDING PROCESSES, LTD. and E. J. CLARKE. Brit. 285,674, March 29, 1927. Electrodes for arc welding of Al and its alloys (other than Al bronze) are made with a core of Al or Al alloy coated with a flux contg. a reducing agent such as C, charcoal or sawdust, to form a reducing atm. around the arc. The core may be coated with other metals such as Cu or Ni for alloying with the Al or assisting in preventing formation of Al oxide, and metals such as Cu, Ni or Si may be added to the coating compn. for the same purpose. Numerous details and compns. of different fluxes are given.

Automatic electric arc welding apparatus. ALLIS M. MACFARLAND (to Westinghouse Elec. & Mfg. Co.). U. S. 1,689,882, Oct. 30.

Apparatus for making sheet-metal pipe by electric resistance welding. FREDERICK L. WILLIAMS. U. S. 1,689,374, Oct. 30.

Welding ferrous metals. GEORGE N. STEIGERWALD (to Union Trust Co. of Cleveland, Ohio). U. S. 1,688,360, Oct. 23. A seam is welded along points of contact of pieces to be united and after the seam has been allowed to solidify it is retraced with a C arc to melt the surface of the seam, relieve internal stresses and improve the characteristics of the metal along the seam.

Soldering mixture. HENRY C. P. WEBER (to Westinghouse Elec. & Mfg. Co.). U. S. 1,689,899, Oct. 30. NH_4Cl is mixed with a plurality of metal halides such as SnCl_2 and $(\text{NH}_4)_2\text{SnCl}_4$ which fuse below the melting temp. of Al or other metal to be soldered and are reduced to the metallic state by the latter.

10—ORGANIC CHEMISTRY

CHAS. A. ROULLER and CLARENCE J. WEST

Structure symbols. INGO W. D. HACKH. *Chemist and Druggist*, 108, 208(1928); cf. C. A. 13, 2197.—The symbols are explained, with illustrations. S. WALDBOTT

Application of Röntgen analysis to problems of stereochemistry. JARL A. WASASTJERNA. *Finska Kemistsamfundets Medd.* 34, 59–67(1925). HANS C. DUUS

The number of possible isomers of the saturated hydrocarbons. LEON DAVID. *Rev. gén. Sci.* 39, 142–3(1928).—Mathematical formulas are given for calcg. the possible isomers of the satd. hydrocarbon series up to $\text{C}_{11}\text{H}_{24}$. Starting with CH_4 and ending

with $C_{14}H_{30}$, the no. of isomers given is, resp., 1, 1, 2, 3, 5, 9, 18, 35, 75, 159, 355 and 1858. R. C. ROBERTS

The action of nitrosyl chloride on 2,2,4-trimethylpentane. P. A. FOOTE AND EDWARD KREMERS. *Am. J. Pharm.* 100, 599(1928).—Because of the tertiary H atom, the secondary reactions in this case will naturally be different from those involved in the action of this reagent on the normal hydrocarbons. The hydrolysis, in small part, of this heterocyclic isonitroso compd. is indicated by the formation of a small quantity of a volatile substance with a camphor-like odor and of NH_4OH . W. G. GAESSLER

The action of nitrosyl chloride on pentadecane. P. A. FOOTE AND EDWARD KREMERS. *Am. J. Pharm.* 100, 600(1928).—The presence of pentadecane in *Kaempferia galanga* L. was established by Van Romburgh. On account of its biochem. significance it seemed desirable to prove its normal character by chem. means. For this purpose the $NOCl$ reaction seemed best suited. The preliminary work in this direction, however, has shown that the reaction is not as one-sided as hoped for. The isolated hydrocarbon revealed the same phys. consts. as those recorded by Van Romburgh. The reaction with $NOCl$, however, yielded appreciable quantities of chlorination products. Their formation is explained. Because of the expense of pentadecane the further study of these reactions with heptane is contemplated. W. G. GAESSLER

Polymerization of olefins. R. VAN WINKLE. E. R. Squibb & Sons. *J. Am. Pharm. Assoc.* 17, 544-7(1928).—Propylene was mixed with activated floridin and the mixt. allowed to stand for two months under pressure to remove impurities. Contrary to expectations large amounts of polymerized olefins were obtained. By fractional distn. and mol.-wt. detns. it was concluded that the product formed is a mixt. of several polymers of propylene higher than a pentamer. Isobutylene was treated with activated floridin in a 24-inch column without pressure. Polymerization takes place but the reaction was increased if pressure be employed. Several polymers of isobutylene higher than a tetramer were found. L. E. WARREN

The monomagnesium derivative of acetylene. V. GRIGNARD, L. LAPAYRE AND TCHOU FAKI. *Compt. rend.* 187, 517-20(1928).—Passing C_2H_2 through $PhMgBr$ in Et_2O gave a soln. from which CO_2 released 28% $CH : CCO_2H$ and 13% ($: CCO_2H$). If the reaction mixt. above is heated slightly and well stirred the yields are increased to 62% and 10%, resp. Passing C_2H_2 through $EtMgBr$ under 0.5 atm. pressure gave a di-Mg deriv. of C_2H_2 . Replacing part of the Et_2O with 50 g. of C_6H_6 and heating this soln. to 65° gave 80-81% of the mono-Mg deriv. Adding $PhCH_2Br$ to this product and heating for several hrs. gave 70% $PhCH_2C : CH$, b_{17} 71-3°, n_D^{23} 1.53481, d_4^{25} 0.931; 8% ($: CCH_2Ph$)₂ and 12% C_2H_2 liberated by hydrolysis. This same reaction carried out in Et_2O at 45° gave on carbonation 78% $CH : CCO_2H$ and 8% ($: CCO_2H$)₂. This reaction was repeated at -10° and allyl bromide was added, giving 75% allylacetylene, $b.$ 41-2°, n_D^{22} 1.3653, d_4^{22} 0.777, and a small quantity of a compd., $b.$ 120-5°, which is probably allyl-3-allylacetylene. By using $BuBr$ similarly, 72% hexine, $b.$ 71-2°, d_4^{17} 0.720, n_D^{19} 1.402, is produced. The authors predict that by increasing the pressure to 1 atm. a complete transformation of the di- to the mono-Mg deriv. can be made and that this method of prepn. will be more practical and economical than those starting with aldehydes or ketones. R. C. ROBERTS

Decomposition of organic compounds at high temperatures and pressures. LEE R. HERNDON AND E. EMMET REID. Johns Hopkins Univ. *J. Am. Chem. Soc.* 50, 3066-73(1928).—A study is reported of the decompn. of org. compds. at const. vol., const. temp. (between the limits of 300-525°), at const. pressure and for periods of time ranging from 2 to 48 hrs., the temp. and duration of heating depending upon the stability of the compd. under investigation. In the decompn. of alcs., there seem to be 2 simultaneous reactions: Dehydration and subsequent polymerization of the hydrocarbon residues and dehydrogenation followed by the splitting off of CO and then polymerization. Three distinct types of compds. were derived from these decompns.: Gaseous, H_2O -insol. portion and H_2O -sol. portion. Results are given for $MeOH$, $EtOH$, $PrOH$, Me_2CHOH , $BuOH$, Me_2CHCH_2OH , Me_3COH , $AmOH$, $PhCH_2OH$, $PhCH_2CH_2OH$ and fenchyl alc. The following compds. were also studied: $AcOH$, $BzOH$, adipic, citric and stearic acids, AcH , BzH , C_7H_{16} , C_8H_{18} , $PhMe$, $PhEt$, $PhCHMe_2$, $PhCMe_3$, $MeCHPh_2$, $CHCl_3$, $AcOEt$, Et_2O , $(CH_3OH)_2$, $[CH_2(OH)CH_2]_2O$, Me_2CO , Ph_2CO , $PhOH$, $C_6H_4O_2$ and sucrose. The original should be consulted for details of the products formed. C. J. WEST

Addenda to "Syntheses with diazomethane." F. ARNDT, B. EISTERT AND J. AMENDE. *Ber.* 61B, 1949-53(1928).—A brief discussion of a no. of papers on the subject which have appeared since the last one of the authors (*C. A.* 22, 2930). C. A. R.

β -Chloro-substituted arsenic compounds. VISSEVOLOD V. NEKRASOV AND ALEXANDER S. NEKRASOV. *Ber.* 61B, 1116-21(1928).— C_2H_4 and $AsCl_3$ in the presence of $AlCl_3$ give mixts. of β -chlorovinylarsines which with alkalis again split off the C_2H_4 ; with the primary arsine, $ClCH:CHAsCl_2$, this cleavage is rapid and quant., even in the cold. It remained to be detd. whether the β -chloroethylarsines undergo a similar reaction. $ClCH_2CH_2AsCl_2$ (I) is obtained only in quite unsatisfactory yield from C_2H_4 , $AsCl_3$ and $AlCl_3$; $HOCH_2CH_2Cl$ was accordingly converted with Na_2AsO_3 into $HOCH_2CH_2AsO_3H_2$ (II), which, without being isolated, was reduced with SO_2 to $HOCH_2CH_2AsO$ (III); this with HCl gas evolves heat and forms $HOCH_2CH_2AsCl_2$ (IV), while with PCl_5 the HO group is also replaced by Cl and I is obtained in good yield; without doubt other β -substituted primary and secondary arsines and their derivs. can also be prepd. in this way (cf. following abstr.). Aq. alkalis decomp. I, even in the cold, quant. into C_2H_4 and the alkali arsenite and chloride. The mechanism of the decompn. is undoubtedly the same as that of the decompn. of the vinyl compds.; there is probably first formed an addn. product, $ClCH:CHAsCl_2(OH)K$, which very readily decomps. into $KCl + ClCH:CHAsCl_2(OH)$ and the latter by addn. of another mol. of KOH and splitting off of KCl gives $ClCH:CHAs(OH)_2$, which then adds a 3rd mol. of KOH to form $ClCH:CHAs(OH)_3K$; when this last substance again loses KCl it forms a very unstable compd. with a 3-membered heterocyclic ring, $CH:CH.As(OH)_3$, which

at once decomps. into C_2H_4 and H_3AsO_3 . Oxidizing agents convert I into β -chloroethylarsonic acid (V), which titrates, not very sharply, with Me orange as a monobasic and with phenolphthalein as a dibasic acid. The formation of the β -chloroethylarsines cannot be explained on the assumption, adopted by Lewis and Stiegler for the vinyl compds., of a primary addn. of $AlCl_3$ to the unsatd. hydrocarbon, for the assumed addn. product would have the structure $Al(CH_2CH_2Cl)_3$ and, having no double bonds, would be unable to add $AsCl_3$. It may be assumed with great probability, however, that the formation of both $ClCH:CHAsCl_2$ and I is merely a special case of the Friedel-Crafts reaction: $C_2H_4 + AsCl_3 = HCl + CH_2:CHAsCl_2$ and $CH_2:CHAsCl_2 + HCl = I$. I (17 g. from 318 g. $AsCl_3$ and 60 g. $AlCl_3$ satd. at 0° with dry C_2H_4 (about 70 l.), or 14 g. from 30 g. III with 30 g. PCl_5 in $CHCl_3$), is a mobile, almost odorless liquid, b_D^{20} 89–90°, b_D^{25} 93–4°, d_4^{20} 1.573. III (65 g. from 100 g. $HOCH_2CH_2Cl$ slowly added to 500 cc. Na_2AsO_3 soln. (100 g. As_2O_3) at 100° , followed after 1–1.5 hrs. by the addn. of 30 g. $NaOH$ and 60 g. more $HOCH_2CH_2Cl$ and reduction of the resulting II with SO_2 and a little I), thick odorless oil, d. about 2, decomps. on distn. V, from I and H_2O_2 , m. 133° .

C. A. R.

β -Substituted alkylarsonic acids and their derivatives. S. M. SCHERLIN AND G. EPSTEIN. Techn. Hochschule Moscow. *Ber.* 61B, 1821–5(1928).—Fr. patents 569,541, 556,366 and 585,970 and Engl. patents 191,028 and 191,029 purport to give methods of prepg. $HOCH_2CH_2AsO_3H_2$ from Na_2AsO_3 and $HOCH_2CH_2Cl$, ethylene oxide and $(CH_2Br)_2$ but no properties or const. of the acid are given and Quick and Adams (C. A. 16, 1560) were able by these methods to obtain only thick, non-crystallizable sirups. S. and E. have also obtained only a thick sirup from $HOCH_2CH_2Cl$ with Na_2AsO_3 . Reduction with SO_2 likewise gave no product which could be isolated, and although satn. of the reduction product with HCl yielded a rather difficultly sol. substance, it sepd. as an oil and decompd. rapidly on attempted distn. *in vacuo*; acetylation of this oil with Ac_2O gave a compd. (I), which distd. *in vacuo* without decompn. and had the compn. of β -acetoxyethylchloroarsine, also obtained very easily even with 80% $AcOH$ if the reaction mixt. is at the same time satd. with HCl . When sapond. with alkali or boiling H_2O , I splits off C_2H_4 quant. With PCl_5 or, better, with excess of $POCl_3$, $HOCH_2CH_2AsCl_2$ yields $ClCH_2CH_2AsCl_2$ (II), which behaves toward sapon. agents very much like I and on cautious oxidation yields $ClCH_2CH_2AsO_3H_2$ (III). With $COCl_2$ $HOCH_2CH_2AsCl_2$ gives an oil having the pronounced odor of $CICO_2Et$, which on vacuum distn. loses CO_2 and yields II. With Ph_2NH II gives (as found with N. A. DZBANOVSKY) phenarsazine chloride. I, b_{p-10} $120-1^\circ$, d_{20}^{20} 1.6766. II, b_D 80.6°, b_D^{25} 87°, b_D^{30} 90.8°, d_{20}^{20} 1.8401, has a faint but somewhat penetrating odor. III, m. 134° .

C. A. R.

Trypanocidal action and chemical constitution. VIII. Derivatives of β -aminoethyl- and γ -aminopropylarsonic acids. GEORGE A. C. GOUGH AND HAROLD KING. National Inst. for Medical Research, Hampstead. *J. Chem. Soc.* 1928, 2426–47; cf. C. A. 22, 959.—Although many aromatic compds. contg. As have been synthesized and tested pharmacologically, our knowledge of the aliphatic series is still unsatisfactory, since the aliphatic compds. which have been hitherto examd. for trypanocidal action

are without the amphoteric characteristics which so often accompany activity in the aromatic series. Any new investigation in this field should include the synthesis of a series of aminoaliphatic arsonic acids, which, by reason of their small mol. wt. and their similarity to the NH_2 acids derived from the tissues, should possess a greater power of penetration and a more favorable distribution. For this purpose a series of compds. of the general type $\text{RR}'\text{N}(\text{CH}_2)_n\text{AsO}_3\text{H}_2$, where R and R' are H or aliphatic or alicyclic radicals, was prep'd. Two methods of synthesis are possible: The action of NaH_2AsO_3 on $\text{RR}'\text{N}(\text{CH}_2)_n\text{Cl}$ (Meyer's reaction) and the action of amines on $\text{Cl}(\text{CH}_2)_n\text{AsO}_3\text{H}_2$. The 1st method was unsuccessful. $\text{ClCH}_2\text{CH}_2\text{NEt}_2$ (Brit. Pat. 167,781(1921)), b_p 51-2° (HCl salt, m. 210-1°; picrate, m. 116-7°; chlorbaurate, m. 68-71°), was largely unattacked when treated with NaH_2AsO_3 , though small quantities of alc. and unsat'd. amine were detected. MeI gives Me β -chloroethyldiethylammonium iodide, m. 219-20°, turns yellow or red on exposure to air, when wet with solvent; the chloride, highly deliquescent needles (chloroaurate, m. 202-4°), does not react with NaH_2AsO_3 . It was then found that $p\text{-MeC}_6\text{H}_4\text{SO}_3\text{Me}$ and NaH_2AsO_3 give a small yield of MeAsO_3H_2 , isolated as the Ca salt. However, the only product obtained from $\text{Et}_2\text{NCH}_2\text{CH}_2\text{OH}$ and $p\text{-MeC}_6\text{H}_4\text{SO}_3\text{Cl}$ was tetraethylpiperazinium di- p -toluenesulfonate, m. 300-1°; diiodide, needles, does not m. 300°; dichloroaurate, plates; both of these products were also obtained by the polymerization of free $\text{Et}_2\text{NCH}_2\text{CH}_2\text{Cl}$. $\text{HOCH}_2\text{CH}_2\text{AsO}_3\text{H}_2$ (Brit. Pat. 191,028(1922)) forms a Ca salt, crystg. with 1 H_2O ; reduction of the crude acid from 100 g. $\text{ClCH}_2\text{CH}_2\text{OH}$ in conc'd. HCl contg. a little KI with SO_2 (sat'd. at 50° and allowed to stand 48 hrs.), followed by the action of SOCl_2 in petrol. ether, gives 60 g. $\text{ClCH}_2\text{CH}_2\text{AsCl}_2$, b_p 92-3°; the synthesis of Renshaw and Ware (C. A. 20, 364) is discussed and an improved method of isolating the product of the reaction is given. Oxidation of 57 g. of the arsine with Cl_2 and H_2O gives 35 g. of β -chloroethylarsonic acid (I), m. 134-5°; the max. tolerated dose per g. of mouse (MTD) is 0.2 mg. I (5 g.) and 3.3 g. $\text{CO}(\text{NH}_2)_2$ in H_2O (H_2O is added from time to time to liberate NH_3 by hydrolysis) give 4.1 g. of triethylamine- β,β',β'' -triarsonic acid, m. 184-5° (AcNH_2 or AcONH_2 may also be used as sources of NH_3); the Ca and Ba salts are cryst., the Mg salt amorphous. I (3 g.) and 2 cc. H_2O , heated at 100° and 33% MeNH_2 added to keep the whole neutral, give after 15 hrs. 1.9 g. methyl-diethylamine- β,β' -diarsonic acid, m. 192-4°, crystg. with 1 H_2O ; MTD 1.5 mg. I and Me_2NH give a mixt. of dimethyldiethylammonium chloride β,β' -diarsonic acid, m. 178°, MTD 3 mg., and, as the principal product, β -dimethylaminoethylarsonic acid, analyzed as the HCl salt, m. 138-40°. I and Me_3N give β -dimethylaminoethylarsonic acid-MeCl, m. 187-8° (decompn.). I (7 g.) and piperidine in EtOH give 7.5 g. β -piperidininoethylarsonic acid-HCl, m. 155-7°; reduction with SO_2 in HCl contg. KI gives β -piperidininoethyldichloroarsine-HCl, m. 126-7° (decompn.); the HI salt, bright yellow, m. 158-9°, gives a colorless soln. in H_2O or EtOH. $\text{Cl}(\text{CH}_2)_3\text{OH}$ and NaH_2AsO_3 at 50-60° give γ -hydroxypropylarsonic acid (II), analyzed as the Ca salt; reduction with SO_2 gives γ -chloropropyldichloroarsine (III), b_p 120-2°; oxidation with Cl_2 and H_2O give γ -chloropropylarsonic acid (IV), m. 146-8°, MTD 0.1 mg.; the Ba and Ca salts are cryst. The reaction of II and SO_2 also gives a di-ester of II and III, $(\text{AsCl}_2\text{C}_3\text{H}_6\text{O})_2\text{AsC}_3\text{H}_6\text{OH}$, b_p 35°, which gives III with SOCl_2 ; the residue contains still higher condensation products, with 41-42% As. IV and NH_4OH (d. 0.88), heated 8 hrs. at 110°, give γ -aminopropylarsonic acid, m. 212-4°, MTD 0.4 mg. Me_2NH gives the γ -dimethylamino deriv., analyzed as the HCl salt, slightly deliquescent, m. 108-10°, MTD 0.4 mg. Me_3N gives γ -dimethylaminopropylarsonic acid-MeCl, m. 174-6°, MTD 0.3 mg. γ -Propylaminopropylarsonic acid, m. 222-4°; HCl salt, m. 210-2°, MTD 0.5 mg.; m -nitrobenzoyl deriv., m. 132-4°; the Bz deriv. is an oil. γ -Propylaminopropyldichloroarsine-HCl, m. 195-6°, MTD 0.0075 mg.; it renders trypanosomes non-infective at a diln. of 1:40,000 in horse serum after 4.5 hrs. contact. γ -Hexylaminopropylarsonic acid-HCl, m. 221-3°, MTD 0.025 mg.; m -nitrobenzoyl deriv., m. 118-20°, MTD less than 0.025 mg.; carbethoxy deriv., m. 58-60°, MTD 0.005 mg.; phenylcarbamyl deriv., m. 118-24°, MTD 0.01 mg. γ -Hexylaminopropyldichloroarsine-HCl, m. 190-2°. l - α -Phenylethylaminopropyldichloroarsine-HCl, m. 194-6°, MTD 0.005 mg. γ -Piperidinopropylarsonic acid-HCl, m. 162-4°; reduction gives γ -piperidinopropyldichloroarsine-HCl, m. 194-6°, MTD 0.01 mg. IV and vinylacetonealkamine in EtOH give γ -4-hydroxy-2,2,6-trimethylpiperidinopropylarsonic acid, deliquescent, m. 162°, MTD 0.2 mg. Reduction of the 4-bromo-2,2,6-trimethylpiperidine with AcOH and Zn gives 2,2,6-trimethylpiperidine, b_p 138-9°; HCl salt, m. 236-7°; chloroaurate, m. 127-9°; picrate, m. 195-6°; with IV this gives γ -2,2,6-trimethylpiperidinopropylarsonic acid, m. 150-60°, MTD 2 mg. IV and piperazine hydrate, heated 20 hrs. at 100°, give γ -piperazinopropylarsonic acid di-HCl, MTD 2 mg.; Bz deriv., m. 204-6° (decompn.), MTD 0.2 mg. IV and Et-

nepicotate give γ -3-carbethoxypiperidinopropylarsonic acid, amorphous, deliquescent, MTD 1.5 mg. $\text{CH}_3(\text{CH}_2\text{OH})_2$ and $\text{p-MeC}_6\text{H}_4\text{SO}_3\text{Cl}$ with $\text{C}_4\text{H}_5\text{N}$ at 0° give trimethylene-glycol di-*p*-toluenesulfonate, m. $93-4^\circ$; if the $\text{p-MeC}_6\text{H}_4\text{SO}_3\text{Cl}$ is added in 1 lot and the reaction allowed to proceed without cooling, there results propane- α,γ -dipyridinium di-*p*-toluenesulfonate, m. $118-20^\circ$; aq. HgCl_2 gives the mercurichloride, $\text{C}_{12}\text{H}_{12}\text{N}_2\text{Cl}_2 \cdot 4\text{HgCl}_2$, from which, with H_2S , there is formed the dichloride; dichloroaurate, light yellow, does not m. 300° ; *dipicrate*, m. 176° . Possible reasons for the lack of therapeutic activity of most of these compds. are advanced. C. J. WEST

Alkyl orthosilicates. A. W. DEARING AND E. EMMET REID. Johns Hopkins Univ. J. Am. Chem. Soc. 50, 3058-62(1928).— $\text{Si}(\text{OEt})_4$ is obtained in 70% yield by adding SiCl_4 dropwise to abs. EtOH cooled in a freezing mixt., removing the HCl by dry air and fractionating in a vacuum with careful exclusion of moisture. Bu ester, b_p $160-5^\circ$, d_4^{25} 0.9353, d_4^{25} 0.9194; Am ester, b_p $145-50^\circ$, d_4^{25} 0.9117, d_4^{25} 0.8933; heptyl ester, b_p $200-15^\circ$, d_4^{25} 0.9097, d_4^{25} 0.8958; octyl ester, b_p 240° . $\text{PhCH}_2\text{CH}_2\text{OH}$ gave a product which could not be purified by distn. in vacuum; the product was 88% pure. $\text{ClCH}_2\text{CH}_2\text{OH}$ gave a product 94% pure; with PhNH_2 , HCl this gives an amorphous product, apparently $\text{Si}(\text{C}_6\text{H}_5\text{NHPH})_4$. SiCl_4 and iso-PrOH give iso-PrCl and C_6H_6 . EtSH does not react under the usual conditions; even at 200° the reaction is slow. $\text{Si}(\text{OEt})_4$ and $\text{C}_6\text{H}_5(\text{CO})_2\text{O}$ give $\text{C}_6\text{H}_5(\text{CO}_2\text{Et})_2$ and $\text{SiO}(\text{OEt})_2$. Ac_2O likewise gives AcOEt . BzOH reacts slowly, giving BzOEt but $p\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ does not react; neither does PhOH , $\beta\text{-C}_{10}\text{H}_7\text{OH}$ or PhSH . With AlCl_3 , C_6H_6 and $\text{Si}(\text{OEt})_4$ give Et derivs. even up to C_8Et_4 . When $\text{Si}(\text{OEt})_4$ or $\text{Si}(\text{OMe})_4$ reacts with H_2O or AcOH , the acid seps. as a gel, which is free of strong electrolytes. A non-aq. gel may be obtained by using AcOH and removing the excess AcOH by washing with C_6H_6 ; this is an excellent catalyst for vapor-phase esterification but its absorption from H_2O soln. is practically identical with that of the regular gel. C. J. WEST

Autoxidation of Grignard magnesium compounds. JAKOB MEISENHEIMER AND WALTER SCHLICHENMAIER. Univ. Tübingen. Ber. 61B, 2029-43(1928); cf. C. A. 22, 2365.—It had been found that when an Et_2O Grignard soln. is decompd. with H_2O and the $\text{Mg}(\text{OH})_2$ and Mg halide, MgX_2 , are titrated with HNO_3 and AgNO_3 , the ratio $\text{OH}^-:\text{X}^-$ the more nearly approaches 1:1 the more smoothly the reaction has proceeded, i. e., the less a Wurtz synthesis has come into play as a side reaction. With iodides, however, the method gives entirely erroneous results if, before the decompn. with H_2O , the soln. is greatly dild. with Et_2O . This influence of dildn. has now been more thoroughly studied and found to be due to O. The effect of dildn. is always such as to increase the ratio $\text{OH}^-:\text{I}^-$, e. g., from 1:1 to 1.5:1, although the sum $\text{OH}^- + \text{I}^-$ undergoes no change. If dry CO_2 -free air is passed through or over the Et_2O soln. without dildg. it, the ratio is greatly shifted, whereas with N there is no change. After the decompn. with H_2O the I which cannot be detd. by titration with AgNO_3 can be quant. distd. over and pptd. as AgI in alc. AgNO_3 , and by means of PhNMe_2 it was found that with MeMgI solns. this volatile I is in the form of MeI , not EtI , thus excluding the Et_2O as playing any role in the formation of the volatile I compd. In the absence of O, dildn. alone has no influence on the ratio $\text{OH}^-:\text{I}^-$. PhMgI behaves like MeMgI , although the effect of dildn. (in the presence of O) is less than with MeMgI . From the work of earlier investigators on the action of O on Grignard solns. there can be no doubt that MeMgI and EtMgI give as chief products MeOH and EtOH along with MeI and EtI . The reaction of aromatic Mg compds. is more complicated and the results obtained with the bromides (with which all previous work had been done) cannot be applied directly to iodides. Accordingly an expt. was carried out with the PhMgI prepd. from 25.5 g. PhI ; there were obtained 10% Ph_3 , 19.5% PhI , 18% Me-PhCHOH and 8.5% PhOH . Detn. of the limiting value of the dildn. effect afforded an important insight into the mechanism of the oxidation process. At first the effect of dildn. is very large but becomes almost undetectable when the ratio $\text{OH}^-:\text{I}^-$ has reached the value of about 1.8:1, and even correcting for the fact that the original Grignard solns. used always contained a little MgI_2 whose I naturally plays no part in the shifting of the ratio, the value of the latter never exceeds 2:1 even at the greatest dildn., indicating that MeI is split off from only 1 out of every 3 mols. of MeMgI , the other 2 giving MeOH : $3\text{MeMgI} + 3\text{O} = \text{MeI} + \text{MgO} + 2\text{MeOMgI}$. Am $_2\text{O}$ solns. behave just like those in Et_2O . The effect of dildn. is the same at -20° , room temp. and the temp. of boiling Et_2O ; so it cannot be ascribed to a greater heating, during the oxidation in the more concd. solns. EtMgI behaves like MeMgI . With PhMgI , however, the highest value for the ratio $\text{OH}^-:\text{I}^-$ attained is 1.67:1 (cor.), corresponding to the formation of 1 mol. PhI out of every 4 mols. PhMgI ; in view of the products actually

isolated (see above) the reaction may be represented thus: $4\text{PhMgI} + 3\text{O} + \text{Et}_2\text{O} = \text{PhI} + \text{MgO} + \text{PhCH(OMgMe)}_2 + \text{C}_2\text{H}_6 + \text{HOMgI} + \text{PhOMgI}$. The ratio of mols. Grignard compd. to atoms O actually absorbed was found to be about 1:0.95 for the aliphatic, 1:0.66 for the aromatic derivs.; as the true value in the 1st case is undoubtedly 1:1, it is quite likely in the 2nd to be 1:0.75, as demanded by the above equation. With the aliphatic compds. no, or almost no CH_4 or C_2H_6 is formed. Alkyl- and arylmagnesium bromides show the shifting in the ratio HO^-Br^- on oxidation with air to a much less marked degree but it also increases with increasing diln.; the ratio of mols. PhMgBr to atoms O actually absorbed is 1:0.69. Apparently in concd. solns. there are 2 concurrent series of successive reactions, the 1st of which leads to the splitting off of alkyl or aryl iodide. As the 2nd is slowed up extraordinarily by diln. it may be assumed to be of a higher order (say dimol.) than the 1st (monomol.). The results given above can hardly be explained otherwise than by assuming that there is first formed with immeasurable velocity a complex contg. 3 atoms O and 1 or, more probably, 2 atoms Mg (e. g., $\text{MeMgI} \dots 3\text{O} \dots \text{MgIme} \cdot \text{Et}_2\text{O}$). This complex reacts with still great (although lesser) velocity in 2 ways: (a) monomol., whereby the two I atoms are expelled by the O, with formation of $[\text{MeMg} \dots 3\text{O} \dots \text{MgMe} \cdot \text{Et}_2\text{O}] + \text{I}_2$, the new complex changing to $\text{MgO} + \text{Mg(OMe)}_2$ and the I_2 reacting instantly with unchanged MeMgI to form MeI and MgI_2 ; (b) dimol., oxidizing another mol. MeMgI to MeOMgI ; in the resulting complex $\text{MeMgI} \dots 2\text{O} \dots \text{MgIme}$ the oxidation potential is so diminished that it can no longer expel the I atoms, so that the two Me groups are merely oxidized to MeO . In dil. solns. (b) disappears; with the bromides, because of the greater firmness of the union of the Br to the Mg (b) predominates under all conditions. The difference between aliphatic and aromatic compds. is essentially that with the latter the Et_2O is oxidized. C. A. R.

Action of metallic tin on methylene halides. K. A. KOZESHKOV. I. Univ. Moscow. *Ber.* 61B, 1659-63(1928).— CH_2Br_2 and CH_2I_2 heated with Sn in sealed tubes at $180-90^\circ$ and then at $215-20^\circ$ give compds. of the type MeSnX_3 . The reaction can probably be represented as follows: $\text{CH}_2\text{X}_2 + \text{Sn} = \text{CH}_2\text{SnX}_2$; $2\text{CH}_2\text{SnX}_2 + \text{CH}_2\text{X}_2 = 2\text{MeSnX}_3 + \text{C}$. Along with the CH_3SnX_3 was obtained a black powder with all the properties of C, and no gaseous products were formed. With CH_2I_2 it is difficult to avoid the direct action between Sn and I and the main product is SnI_4 . For the prepn. of CH_2Br_2 the Klinger-Auger method for the prepn. of CH_2I_2 from CHI_3 was applied to CHBr_3 ; yield, about 80% CH_2Br_2 , $b_{754} 97.5^\circ$, $d_4^{20} 2.4953$, $n_D^{20} 1.5420$. The MeSnBr_3 , m. 51° , $b_{746} 210-1^\circ$; yield, 90% from 7.93 g. Sn and 18 g. CH_2Br_2 ; when 19.5 g. CH_2Br_2 is used to 5 g. Sn, considerable HBr is liberated and 14 g. SnBr_4 is formed. C. A. R.

Chemical constitution of aldehyde and ketone bisulfites. II. G. SCHROETER, WITH M. SULZBACHER. Tierärztl. Hochschule, Berlin. *Ber.* 61B, 1616 27(1928); cf. C. A. 21, 386.—In the 1st paper it was shown that $\text{Me}_2\text{C(SO}_3\text{Ph)}_2$ (I) heated with alkalis in excess decomps. into PhOH and salts of $\text{HOCMe}_2\text{SO}_3\text{H}$ (II) and H_2SO_3 . Raschig and Prah! have recently (C. A. 22, 1571) confirmed the quant. course of this decompn. as far as the H_2SO_3 is concerned but cast doubt on it as regards the salts of II, which they were able to obtain pure only with difficulty. S. and S.'s expts., however, carried out repeatedly on both a large and a small scale, have shown that the decompn. proceeds practically quant. in the way indicated above, and the failure of R. and P. to obtain the Ba salt, e. g., of II in pure form directly may have been due to their using com. instead of pure Ba(OH)_2 for the decompn. The com. product, as is known, contains impurities, especially BaCl_2 , and the latter, because of the high soly. of the Ba salt of II, accumulates with this salt in the mother liquors and naturally greatly influences the analytical results. Their method of purification through the Cu salt by double decompn. of the Ba salt with CuSO_4 is impracticable; it is better to ppt. the Ba quant. with H_2SO_4 (i. e., in acid soln.) and neutralize with freshly pptd. CuO . In this way the pure Ba salt quant. gives the green Cu salt $(\text{HOCMe}_2\text{SO}_3)_2\text{Cu} \cdot 3\text{H}_2\text{O}$, which, like the Ba salt, can be recrystd. from aq. Me_2CO or alc. R. and P. tried to recryst. their Cu salt from AcOH , but it is very difficultly sol. in AcOH and although it dissolves completely on long boiling the tertiary HO group is acetylated at the same time and there is obtained the colorless Cu α -acetoxyisopropylsulfonate, which can be recrystd. from Me_2CO . This affords a new proof of the correctness of S.'s formulation, and the unsatisfactory results of R. and P.'s attempts to purify the salts of II are explained, but as the decompn. reaction is important enough to merit a more thorough study, S. and S. have taken it up again. The formation of II is the result of an abnormal sapon. of the I, not of a primary normal sapon. to $\text{Me}_2\text{C(SO}_3\text{Na)}_2$, followed by a splitting off of

one SO_2H group as sulfite, comparable to the formation of a phenol by alkali fusion of a SO_2H acid. For only 2 mols. alkali are used to decomp. $\text{RR}'\text{C}(\text{SO}_2\text{Ph})_2$ ($\text{R} = \text{Me}$, $\text{R}' = \text{Me}$, Et or CH_2CHCH_3), there are obtained, along with the salt of $\text{HOCCR}'\text{SO}_2\text{H}$ (III), sometimes almost exclusively, the salt of the dialkylmethionic acid $\text{RR}'\text{C}(\text{SO}_2\text{H})_2$. These acids are as stable towards excess of hot alkali as $\text{CH}_2(\text{SO}_2\text{H})_2$ itself and its mono-alkyl derivs. but the corresponding methionides with excess of alkali decomp. chiefly, like II, into the salt of III. Such a reaction is termed an abnormal sapon. because aryl esters and alkylanilides of SO_2H acids may be formulated as neutral esters and alkylanilides, $\text{RadS}(\text{O}_2)\text{OR}$, $\text{RadS}(\text{O}_2)\text{NR}_2$, of asym. $\text{HS}(\text{O}_2)\text{OH}$, in which, in general, the O- and N-contg. groups are held more loosely than the radical (Rad) attached to the S through a C union; on sapon., therefore, the former groups are usually split off. But under certain conditions these relations may be reversed; the group Rad is held more loosely than OR or NR_2 and is "sapond." first, with formation of the salt of HSO_2R or HSO_2NR , which then undergoes complete sapon. to the sulfite and phenol or amine: $\text{PhO}_2\text{SCMe}_2\text{SO}_2\text{Ph} + \text{NaOH} = \text{NaSO}_2\text{Ph} + \text{PhO}_2\text{SCMe}_2\text{OH}$ or $\text{EtPhNSO}_2\text{CMeEtSO}_2\text{NEtPh} + \text{NaOH} = \text{NaSO}_2\text{NEtPh} + \text{EtPhNSO}_2\text{CMeEtOH}$. Further evidence of the presence of a HO group in II is afforded by the action of PCl_5 . It had already been shown that when II is treated hot with an excess of PCl_5 it yields $\text{MeC}(\text{CH}_2)\text{SO}_2\text{Cl}$ (IV), probably by replacement of the HO group by Cl and subsequent elimination of HCl. IV with PhNHMe gives *isopropenylsulfonmethylanilide* (V), identical with the compd. obtained by Autenrieth (*Ber.* 34, 3467(1901)) from $\text{MeCH}(\text{SO}_2\text{Cl})\text{CH}_2\text{SO}_2\text{Cl}$ and PhNHMe , to which he assigned the structure $\text{MeCH}:\text{CHSO}_2\text{NMePh}$. On gentle treatment with only 1 mol. PCl_5 , however, II gives α -hydroxyisopropylsulfonyl chloride (VI), converted by PhNHEt into the *ethylanilide* (VII), in which the alc. HO group was detd. quant. by the Zerevitinov method. There remains no doubt, therefore, that the salts of the III are entirely different from the bisulfite compds. of the corresponding ketones. As to the structure of the latter, S. and S. agree with R. and P. that they are not O-esters, $\text{R}_2\text{C}(\text{OH})\text{OSO}_2\text{Na}$, of H_2SO_3 . A unitary formulation for these compds. is therefore no longer possible and they must be considered as being "polymols." Since aldehydes and ketones are known to form mol. compds. with SO_2 , it may be assumed that these very labile dimol. compds. combine with H_2O to form more stable trimols., $(\text{R}_2\text{CO})_2(\text{SO}_2) \cdot (\text{HOH})$, functioning as strong monobasic acids. As long as they are not dissociated, the properties of their individual components are masked because the mol. valences which chiefly condition their chem. properties mutually sat. each other in the polymol. V, m. 58–9°. VI, light yellow, viscous, lachrymatory oil. VII, m. 44.5–45°. C. A. R.

Citronellal and rhodinal. A. VERLEY. *Bull. soc. chim.* 43, 845–54(1928).—To det. whether citronellal (I) has the α or ethylene ($\text{CH}_2:\text{CMe} \cdot \text{CH}_2$ -) linkage ascribed to it by Barbier and others (*Compt. rend.* 118, (1893); 119, (1894); 112, (1896); 122, 737 (1896); 157, 1114) or whether it is a mixt. of α - and the β - or propylene ($\text{Me}_2\text{C}:\text{CH}-$) (assigned by B. to rhodinal), as stated by Harries and Himmelmann (*C. A.* 2, 2807) and Grignard and Dœuvre (*Bull. soc. chim.* 40, 428(1928); cf. *C. A.* 22, 4104), V. prepd. very pure I (b_p 82°, d_{20}^{20} 0.8682, d_4^{20} 0.8668; refractive indices and sp. rotations also tabulated) through its NaHSO_3 compd. The dispersion curve of I was an equilateral hyperbola and its semicarbazone always m. 82° as obtained (83.5° upon recrystn.). Pure rhodinal (II) (b_p 83°, d_0^0 0.8752, d_4^0 0.8751, d_{20}^{20} 0.8709, d_4^{20} 0.8694, α_D^{20} 1°10'; refractive indices also tabulated) was prepd. by vacuum distn. of hydroxycitronellal (III) (b_p 116°, d_{16} 0.931, n_D^{20} 1.456, α_D^{20} (10 cm.) 8°30') in presence of kieselguhr and treatment of the distillate with neutral NaHSO_3 . The dispersion curve of II is rectilinear and its semicarbazone, m. 75° (75.5° after several recrystns.). From the phys. data and because the mixed m. ps. of the semicarbazones were always depressed, I and II must be chem. individuals. The history of III is given. It may be prepd. by the action of H_2SO_4 followed by Na_2CO_3 on the NaHSO_3 compd. of I at low temp.; by forming the cyanohydrin of I, hydrating, and eliminating HCN by vacuum distn.; by acetylating the enol of I with Ac_2O and NaOAc at relatively low temp., hydrating, and sapon. with a weak alkali. III oxidizes easily but may be stabilized by hydroquinone. An attempt to oxidize rhodinol with $\text{Na}_2\text{Cr}_2\text{O}_7$ to II yielded pulegol (β -isopulegol) (b_p 90°, d_0^0 0.9407, d_4^0 0.9406, d_{20}^{20} 0.9275, d_4^{20} 0.9260). V. offers an explanation for the predominance of the α -form among the terpenes and for the development of the β -form. C. H. PRET.

The autoxidation of citronellal (preliminary communication). J. ZIMMERMANN. Buitenzorg Dept. Agr. *Rec. trav. chim.* 47, 940–1(1928).—If Zn is added to citronella oil which is exposed to the action of air and of sunlight, a ppt. of Zn formate begins

to form after a few hrs., the HCO_2H being formed by the oxidation of citronellal, the quantity of which decreases with increasing formation of the $(\text{HCO}_2)_2\text{Zn}$. Moreover, the same phenomenon was observed with pure citronellal, prep'd. by means of the NaHSO_3 comp'd. The HCO_2H can be formed either by the oxidation of the terminal methylene group or by the oxidation of the enolized aldehyde group, the latter conception being preferred by Z. On keeping citronella oil contg. a trace of phenolphthalein, for 1 year, the % of citronellal had only decreased 4%. C. F. VAN DUIN

Chemistry of the three-carbon system. XVIII. Quantitative investigations on the influence of alkyl substituents on the α, β, γ change in unsaturated acids; observations on the reduction of sorbic acid and a new synthesis of pyroterebic acid. ALAN A. GOLDBERG AND REGINALD P. LINSTAD. Imp. College Sci. Tech., South Kensington. *J. Chem. Soc.* 1928, 2343-60; cf. *C. A.* 22, 329.—The position of equil. in the reversible change between α, β - and β, γ -olefinic acids in the presence of alkali appears to be independent of the phys. conditions under which the interconversion proceeds. From a survey of results obtained with the simple mono-olefinic acids contg. no 2nd unsat'd. group, the following generalizations may be drawn: Butenoic acids without γ -substituents (alkyl substituents are meant) show no stability of the β, γ -form even when substituted on the β -C atom. The acids with 1 γ -substituent show a small but definite stability of the β, γ -form, which is not appreciably affected by the nature of the substituent or by the presence of α -substituents. γ -Substituted butenoic acids having a 2nd alkyl group on the γ -C atom show great stability of the β, γ -form and a similar but weaker effect is produced if the 2nd substituent is on the β -C atom. The max. effect in the β -position is given by an Et group. These principles are still valid if the substituting groups form part of a polymethylene ring. Details are given for the prep'n., purification and characterization of $\Delta\alpha$ - and $\Delta\beta$ -pentenoic acids, $\Delta\alpha$ -hexenoic acid (*anilide*, m. 109-10°), $\Delta\beta$ -hexenoic acid (various methods of reducing sorbic acid are discussed), γ -methyl- $\Delta\alpha$ -pentenoic acid (*acid chloride*, b_{20} 67°; *anilide*, m. 119°), γ -methyl- $\Delta\beta$ -pentenoic acid (*acid chloride*, b_{18} 60°; *anilide*, m. 106°; *di-bromide*, m. 99°), α -methyl- $\Delta\alpha$ -pentenoic acid (*acid chloride*, b_{18} 63°; *amide*, m. 80°; *anilide*, m. 84°); α -methyl- $\Delta\beta$ -pentenoic acid (*acid chloride*, b_{17} 47°; *amide*, m. 74°; *anilide*, m. 76°). The % of α, β -acid at equil. was found to be: $\Delta\alpha$ -pentenoic, 75.4; α -methyl- $\Delta\alpha$ -pentenoic, 80.7; γ -Me deriv., 5.6; cyclopentylideneacetic, 13.7. **XIX.** The homomesitones. AILEEN EDITH ABBOTT, GEORGE A. R. KON AND RALPH D. SATCHELL. *Ibid* 2514-24.—In the intermol. condensation of MeEtCO , alk. condensing agents lead to a mixt. of $\text{MeCH}_2\text{CMe:CHCOEt}$ (I), and $\text{MeCH:CMcCH}_2\text{COEt}$ (II), the former predominating especially in the ketone obtained by Bodroux and Taboury's method; acid condensing agents lead to ketones with a branched chain ($\text{MeCH}_2\text{CMe:CMcCOMe}$ (III) and MeCH:CMcCHMeCOMe (IV)), H_2SO_4 giving a ketone of low d., consisting mainly of IV, while HCl yields a ketone of high d. and n , consisting mainly of III; by far the best method is that of Descude (*Ann. chim. phys.* 29, 486 (1903)), which gives III only. The structures of I, III and IV were confirmed by synthesis from the corresponding acids. Details of the condensations are reported. MeEtCO and $\text{MeCHBrCO}_2\text{Et}$ with Zn give *Et* β -hydroxy- α, β -dimethylvalerate (V), b_{13} 89-90°, $d_4^{19.5}$ 0.96457, $n_D^{19.5}$ 1.4319 (75% yield); the liquid acid was dehydrated by Ac_2O , giving a poor yield of α, β -dimethyl- $\Delta\alpha$ -pentenoic acid, b_{18} 116°, $d_4^{17.5}$ 0.97497, $n_D^{17.5}$ 1.45952; *acid chloride*, b_{17} 66°; *p-toluidide*, m. 123°. With MeZnI there results III, b_{20} 65°, $d_4^{17.4}$ 0.86856, $n_D^{17.4}$ 1.45283. *Et* α, β -dimethyl- $\Delta\beta$ -pentenoate, by dehydrating V with POCl_3 in C_6H_6 , b_{13} 69°, $d_4^{21.1}$ 0.92379, $n_D^{21.1}$ 1.43628; the corresponding acid, b_{20} 116°; *acid chloride*, b_{13} 52°; *p-toluidide*, m. 56°. MeZnI gives IV, b_{13} 48°, b_{750} 154°, $d_4^{19.2}$ 0.85385, $n_D^{19.2}$ 1.43768; semicarbazone, m. 203-4°; an isomeric semicarbazone, m. 163°. III also forms 2 semicarbazones, m. 166-7° and 186°. This indicates *cis-trans* isomerism. In the equil. mixt. of III and IV there is $17 \pm 0.25\%$ α, β -ketone. I was synthesized from MeEtC:CHCOCl and EtZnI ; it b_{18} 66°, b_8 53-4°, $d_4^{1.5}$ 0.85516, $n_D^{21.5}$ 1.45073. Attempts to synthesize II failed, only I being formed. II was finally isolated by treating the equil. mixt. from the EtONa condensation with Al-Hg , which reduces I to a high-boiling bimol. condensation product; the II, b_{19} 63°, $d_4^{21.2}$ 0.85244, $n_D^{21.2}$ 1.43668; semicarbazone, m. 134°. The equil. mixt. of I and II contains 67.5% α, β -ketone. C. J. WEST

Superheating of phenyl β, β -dimethylacrylate. SIEGFRIED SKRAUP. Univ. Würzburg. *Ber.* 61B, 1665-6(1928).—Doubt having been cast by v. Auwers (*C. A.* 22, 1762) on the existence of the comp'd., m. 88°, which S. and Beng described as having

obtained by superheating $\text{Me}_2\text{C}:\text{CH}:\text{C}(\text{O}-\text{Me})_2$, the substance of a series of expts. and a sample sent to us were unable to obtain it is that they were unable to obtain it is that they of doing which is emphasized in the first 2 papers of the series (cf. especially C. A. 20, 1228).

and to which they assigned the structure seen prepd. anew in 2 entirely independent series. Possibly the reason he and his collaborators did not strictly control the temp., the necessity of doing which is emphasized in the first 2 papers of the series (cf. especially C. A. 20, 1228).

Preparation of organic esters. MUNIO KOTAKE AND YASUJI FUJITA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 734-9; English Ed. 1, 65(1928).—Good yields are claimed when esters are prepd. by heating a mixt. of alc., acid, H_2SO_4 and anhyd. $\text{Al}_2(\text{SO}_4)_3$ at 100° . Stearic, succinic, benzoic, malonic, maleic, cinnamic, pyromucic, salicylic esters, AmOAc and oxalic acid ester have been successfully prepd. A. I. H.

Organic cyclic polysulfides: condensation of ethylene mercaptan with di- and trichloroacetic acid. GOPAL CHANDRA CHAKRAVARTI AND JOGENDRA MOHAN SAHA. Univ. Science Technol., Calcutta, and Indian Inst. Science, Bangalore. *J. Indian Chem. Soc.* 5, 453-8(1928).—This study is a continuation of the investigations of Rây (cf. C. A. 16, 3065; 18, 2332). A mixt. of 6 g. of $(\text{HSCH}_2)_2$ (I) and 9 g. of $\text{Cl}_3\text{HCCO}_2\text{H}$ (II) was heated for several hrs. on a sand or water bath. CO_2 , H_2S , and HCl were evolved. The reaction product, which was solid after cooling, was washed with dil. caustic alkali and H_2O . The residue was extd. with EtOH , and the ext. concd. Thus *pentamethylene tetrasulfide*, $\text{CH}_2.\text{S}.\text{C}_2\text{H}_4.\text{S}_2.\text{C}_2\text{H}_4.\text{S}$ (III), white, m. 96° , was obtained instead of the

expected *ethylenedisulfido-acetic acid*, $\text{CH}_2.\text{S}.\text{CH}(\text{CO}_2\text{H}).\text{S}.\text{CH}_2$ (IV). Besides III,

the reaction yielded polymers of Et_2S_2 . When I and II were heated together with C_6H_6 as a solvent, no reaction took place, while in xylene *trimethylene disulfide*, $\text{CH}_2.\text{S}.\text{CH}_2.\text{S}.\text{CH}_2$ (V), yellow, m. $192-4^\circ$, and 2 polymers of V were obtained; 1st

polymer, brownish, heavy oil of sweet odor; 2nd polymer, white, m. $83-4^\circ$. Nine g. of $\text{HSCH}_2\text{CH}_2\text{SK}$ and 5.5 g. of the Et ester of II in 50 cc. abs. EtOH gave *Et diethylene tetrasulfido-acetate*, $\text{C}_2\text{H}_4.\text{S}.\text{CH}(\text{CO}_2\text{Et}).\text{S}.\text{C}_2\text{H}_4.\text{S}_2$, thick oil, and *Et ethylenedisulfido-*

acetate, $\text{CH}_2.\text{S}.\text{CH}(\text{CO}_2\text{Et}).\text{S}.\text{CH}_2$ (VI), thick, transparent oil of pleasant odor. The

boiling of VI with KOH in EtOH resulted in formation of a *compd.*, which probably was IV. Interaction of $\text{Cl}_3\text{HCCO}_2\text{K}$ and $\text{HSCH}_2\text{CH}_2\text{SK}$ gave IV, oil of pungent odor, strongly acid to litmus, decomp. carbonates and bicarbonates; *K salt*, colorless crystals. Ten g. $\text{Cl}_3\text{CCO}_2\text{Et}$ (VII) and 10 g. of I gave amorphous *compds.* identified as polymers of Et_2S_2 . The same *compds.* were obtained by interaction of $\text{HSCH}_2\text{CH}_2\text{SK}$ and VII, and of $(\text{NaSCH}_2)_2$ and VII. The reaction between 10 g. of I and 9 g. $\text{Cl}_3\text{CO}_2\text{H}$ in 40 cc. xylene (no reaction occurred in C_6H_6) yielded III and polymers of ethylene disulfide. G. S.

Action of diazomethane on ketones in the presence of catalysts. HANS MEERWEIN AND WILLY BURNELEIT, WITH TH. BERSIN. Univ. Königsberg. *Ber.* 61B, 1840-7(1928); cf. C. A. 22, 1717.—In a continuation of the study of the increase in the ionizing ability of weak electrolytes by complex formation and its significance for catalytic processes, M. and B. have taken up the question of the possibility of activating purely homopolar *compds.* or at. groups (e. g., $\text{C}:\text{O}$) by complex formation, their guiding thought being that by the addn. of suitable complex formers to the O of the CO group there can be brought about a distortion of the electronic paths in the sense that the dipolar moment of the CO group is increased or a spatially enclosed or electrostatically screened dipole is set free, thus increasing the additive power of the CO group. As suitable complex formers may be considered acids, H_2O , alcs. and metallic salts, for the halochromic phenomena of aldehydes and ketones indicate that these substances can add to the O of the CO group. As a reaction to test the additive power of the CO group was chosen that with CH_3N_2 . According to observations hitherto made, ketones do not react with CH_3N_2 and in agreement with this, M. and B. found that an $\text{Me}_3\text{CO}.\text{CH}_3\text{N}_2$ soln. at 0° undergoes only barely perceptible decomp. but if 10-5% H_2O is added to the Me_3CO there sets in a vigorous evolution of N which continues as more CH_3N_2 is passed in. When about 80% of the quantity of CH_3N_2 equiv. to that of the Me_3CO has been used up the mixt. seps. into 2 layers, and the action of the CH_3N_2 becomes slower and finally ceases completely. The lower layer consists of H_2O (approx. the quantity added) and the upper layer contains chiefly *asym*-dimethylethylene oxide (I) (approx. 40% of the calcd.), together with homologs of Me_3CO (MeCOEt , isolated as the semicarbazone, and Et_3CO and MeCOPr , formed in too small quantities to permit

of their sepn. from each other); the small quantity of Me_2CHCHO , detected by its odor and fuchsin- SO_2 reaction, was probably formed secondarily from the I by the dil. H_2SO_4 used in working up the product. The formation of I and MeCOEt can be represented by the scheme

the higher ketones by an entirely analogous reaction of the CH_2N_2 with the MeCOEt formed primarily. The H_2O added is not methylated, or only in traces; no MeOH could be detected with $p\text{-O}_2\text{NC}_6\text{H}_4\text{COCl}$. The H_2O therefore acts purely catalytically, and that it is the non-dissociated H_2O , not H ions, which has this catalytic action is indicated by the fact that 0.1 N NaOH has approx. the same effect. The alcs. act like H_2O , although apparently not quite so energetically, their action decreasing with increasing mol. wt. The products are the same as with H_2O . Metallic salts also catalyze the methylation of ketones by CH_2N_2 . ZnCl_2 , SnCl_4 and SbCl_5 are excluded by their condensing action and HgCl_2 is reduced by CH_2N_2 , but a 0.1 N soln. of LiCl in Me_2CO behaves towards CH_2N_2 about like Me_2CO contg. 10% H_2O , although the reaction stops when about 70% of the Me_2CO has reacted; the yield of I is 31%, based on the quantity of CH_2N_2 used. Whether acids catalyze the reaction could not be detd. experimentally because they are almost instantly methylated by CH_2N_2 , but when CH_2N_2 in Et_2O was titrated with HCl and $(\text{CO}_2\text{H})_2$ in Et_2O on the 1 hand and in Me_2CO in the other, about 10% less acid was required with the Me_2CO than with the Et_2O solns. The effectiveness of these catalysts is not limited to the methylation of ketones; acid esters, amides and even CO react more or less energetically with CH_2N_2 under the above conditions. These reactions have as yet not been carried beyond the qual. stage and the results so far obtained are published now only because of the appearance of Mosettig's paper (*C. A.* 22, 4512); according to M. and B.'s views, the ethylene oxide which he obtained from piperonal and CH_2N_2 in MeOH is β -piperonylpropylene oxide. C. A. R.

Nitramines of methionic acid. H. J. BACKER. Univ. Groningen. *Rec. trav. chim.* 47, 942-9(1928).—The action of abs. HNO_3 at 0° on mono-alkylated amides $\text{CH}_2(\text{SO}_2\text{NHR})_2$ of methionic acid, gives rise to the formation of dinitramines, provided R be an aliphatic radical. These nitramines can also be obtained from the acetylated mono-alkylated amides if the nitration is carried out at higher temp. When R is an aryl group, the NO_2 group enters the C_6H_5 nucleus, but nitramines are not formed. *Methionbismethylamide*, m. $172-5^\circ$, was obtained on heating the $\text{CH}_2(\text{SO}_2\text{Ph})_2$ + ("methionol," according to Schroeter, *C. A.* 13, 3161) with an excess of MeNH_2 in C_6H_6 in a sealed tube at 140° for 3 hrs. With abs. HNO_3 at 0° , *methionbismethylnitramine*, (I), m. 118.5° , is produced. On titrating this compd. with alkali, 4 equivs. are consumed, the nitramine being converted into $\text{CH}_2(\text{SO}_2\text{H})_2$ and MeNHNO_2 , according to the equation: $\text{CH}_2[\text{SO}_2\text{N}(\text{NO}_2)\text{Me}]_2 + 4\text{KOH} = \text{CH}_2(\text{SO}_2\text{K})_2 + 2\text{MeN}\cdot\text{NO}_2\text{K} + 2\text{H}_2\text{O}$. With liquid NH_3 I reacts instantly with the formation of methionamide, m. 234° , and MeNHNO_2 . *Methionbismethylacetamide*, m. $174-5.5^\circ$, prepd. from $\text{CH}_2(\text{SO}_2\text{NHMe})_2$, Ac_2O and a drop of concd. H_2SO_4 , does not react with abs. HNO_3 at 0° , but at 70° is converted into I. In the same way as described above for the Me compd., the following compds. were prepd.: *methionbisethylamide*, m. $144-5^\circ$; *bisethylacetamide*, m. 78° ; *bisethylnitramine*, m. $61-1.5^\circ$; *bispropylamide*, m. 171.5° ; *bispropylnitramine*, m. $47-8^\circ$; *bisbutylamide*, m. $181-1.5^\circ$; *bisbutylnitramine*, m. $41-1.5^\circ$; *bisamylamide*, m. $179.5-80^\circ$; *bisamylnitramine*, m. 21° . *Methiondipiperidide*, m. $117-7.5^\circ$, is converted into nitropiperidine by abs. HNO_3 . The nitration of *methionbisethylanilide*, m. $112-4^\circ$, gives *methionbisethyl-2,4-dinitroanilide*, m. 219° , which is split up by concd. HCl at 175° into $\text{CH}_2(\text{SO}_2\text{H})_2$ and $2,4\text{-(O}_2\text{N)}_2\text{C}_6\text{H}_3\text{NH}_2$, m. 114.5° (cf. *Rec. trav. chim.* 2, 104(1883)). The nitration of $\text{CH}_2(\text{SO}_2\text{Ph})_2$ yields *di-p-nitrophenyl methionate*, m. 169° , treatment with benzene satd. with NH_3 at 150° giving methionamide, m. 234° , and *p*-nitrophenol, m. 113.5° . C. F. VAN DUIN

Reactions relating to carbohydrates and polysaccharides. XVII. Structure of the isomeric methyleneglycerols. HAROLD HIBBERT AND NEAL M. CARTER. McGill Univ. *J. Am. Chem. Soc.* 50, 3120-7(1928); cf. *C. A.* 22, 3132.—The possibility of both optical and geometrical isomerism in the structurally isomeric cyclic acetals of $\text{C}_3\text{H}_5(\text{OH})_3$ is pointed out. Advantage is taken of the absence of geometrical isomerism in the methyleneglycerols (I) in order to isolate and det. the structure of the 2 isomers formed by partition of HCHO between the 1,2- and 1,1'-HO groups of $\text{C}_3\text{H}_5(\text{OH})_3$ during cyclic acetal formation. Details are given for the prepn. of the mixed I (63% yield), b. $80-90^\circ$, n_D^{20} 1.4497 (indicating 60% of the 1,2-deriv.). In the formation of the benzoates, advantage was taken of the action of dry HCl in bringing about a large conversion of the 1,2- into the 1,1'-acetal. Fifty g. I were treated with 0.01%

by wt. of dry HCl and allowed to stand 15 hr. at 100°, then cooled and added to 40 g. dry C₂H₅N; finally 68 g. BzCl was slowly run in so that the temp. was maintained below 60°; after 48 hrs. at 20°, a practically quant. yield of mixed benzoates was obtained; crystn. from Et₂O gives 50% of the 1,1'-benzoate, m. 72°; from the mother liquor, there was isolated the 1,2-isomer, m. 26°. Hydrolysis of these derivs. gave 1,2-methyleneglycerol (II), b₁₁ 64-5°, b₂₈ 104°, b₇₈₀ 195°, d₄²⁰ 1.2113, n_D²⁰ 1.4477, and the 1,1'-isomer (III), b₁₁ 82°, b₂₈ 100°, b₇₈₀ 191°, d₄²⁰ 1.2256, n_D²⁰ 1.4433. The 1'-Me ether of II, b₇₈₀ 147°, d₄²⁰ 1.0788, n_D²⁰ 1.4213; the 2-Me ether of III, b₇₈₀ 152°, n_D²⁰ 1.4295. Hydrolysis of these ethers gives the known α- and β-Me ethers of C₃H₅(OH)₃. The interconversion of the ring systems of the 2 isomeric acetals is studied. C. J. W.

Polymerization and condensation. IV. Experiments on glycidol acetate. P. A. LEVENE AND A. WALT. Rockefeller Inst. *J. Biol. Chem.* 79, 363-76(1928); cf. *C. A.* 22, 59.—Glycidol acetate was allowed to stand for 5 days at 135-40° and for several weeks at 12-3° and the polymerization product fractionated. Among the products obtained were: the dimeric form of glycidol acetate, mol. wt., 226, which on standing was further polymerized; incompletely acetylated glycerol; monoaceticin; triaceticin; and polymers of glycidol acetate. *Conclusion.*—Glycidol acetate has a greater tendency to polymerize than propylene oxide, glycidol or CO(CH₂OH)₂, but a lesser tendency to form condensation products than these substances. MeCOCH₂OAc showed no tendency to polymerize or form condensation products. A. G.

Synthesis of glyceric acid-monophosphoric acid. CARL NEUBERG, FRITZ WEINMANN AND MARTHE VOGT. Kaiser Wilhelm-Institut für Biochemie, Berlin-Dahlem. *Biochem. Z.* 199, 248-52(1928).—When EtPO₃ acts on water-free *D*-glyceric acid a mol. of the ester adds on to the latter. Equal quantities of each substance are mixed and the reaction which sets in spontaneously is completed on the water bath. The unused EtPO₃ is extd. with CHCl₃. After soln. in water various by-products are removed or destroyed by sapon. with acid and later with NH₃. The inorg. phosphoric acid is pptd. with MgCl₂. The liquid is condensed and pptd. with alc., which removes NH₄Cl and MgCl₂ remaining in soln. The sirupy material is dild. with H₂O and is heated with BaCl₂ (reaction alk. to phenolphthalein); the neutral Ba salt of glyceric acid-monophosphoric acid seps. out pure. This can be further purified as the brucine salt. S. M.

Configuration of pentaerythritol. II. The optically active dipyruvic acid-pentaerythritols. J. BÖESKEN AND B. B. C. FELIX. Techn. Hochschule Delft. *Ber.* 61B, 1855-7(1928); cf. *C. A.* 22, 2367.—It was concluded, in the 1st paper, that if it were possible to resolve condensation products of pentaerythritol (I) with ketones of aldehydes of the type C(C₂H₅O₂:CRR')₂ into optically active components, the tetrahedral structure of I, at least in the liquid state, would be proved. The dipyruvic acid deriv. briefly mentioned in that paper has since been prepd. in larger quantity and resolved by means of strychnine. AcCO₂H (190 g.) is esterified practically completely by boiling 8 hrs. with 1 l. abs. alc. + 20 cc. alc. 2 N HCl, adding 500 cc. C₆H₆ and slowly distg. off about 1 l. of EtOH-C₆H₆-H₂O through a long fractionating column. The ester is then boiled 3 hrs. with 1.5 l. abs. alc., 65 g. I and 30 cc. alc. 2 N HCl, 0.5 l. C₆H₆ added, the ternary mixt. distd. off as above and the process repeated, giving 94 g. b.-cathode vac. 130-5°, 12 g. b. 135-40° and 36 g. b. 140-65°. The 1st fraction (mol. wt. detd. by sapon. 331.6) is *di-Et dipyruvate-pentaerythritol*, C(C₂H₅O₂:CMeCO₂Et)₂, m. 46°, 50 g. of which with 1.10 N alc. NaOH at 80° gives 25 g. of the free acid (II), m. 238°, mol. wt. (by titration) 275. The 140-65° fraction above consists chiefly of the monopyruvate ether, m. 95°, mol. wt. 222. II (11 g.) with 12.5 g. strychnine in alc. suspension heated to 70° (which quickly gave a clear soln.) and poured into petroleum ether gave 23.5 g. of a salt of which 11 g. did not dissolve in 40 cc. alc.; 10 g. of this insol. salt, decompd. in H₂O with KOH, filtered from the strychnine, shaken with CHCl₃, acidified to Congo at 0° with H₂SO₄ and extd. with Et₂O yielded 2.5 g. of an active II, [α]_D -3.98° (Me₂CO). From the sol. strychnine salt was obtained in the same way 2.5 g. of a II with [α]_D 3.72° (Me₂CO), 6.87° (H₂O); in H₂O and even in the presence of a little HCl the rotation remains const. for 24 hrs. but on the H₂O bath rapidly decreases (22% racemization in 2, 100% in 45 min.). C. A. R.

The formation from β-alanine ester of a high-molecular product composed of β-alanyl groups in acid-amide linkage. EMIL ABDERHALDEN AND FRITZ REICH. Univ. Halle. *Z. physiol. Chem.* 178, 169-72(1928).—In attempting to prep. β-alanine anhydride it was found that β-alanine ester on standing deposits a white amorphous substance and completely solidifies in 6-7 days. The product is sol. in H₂O and in AcOH, and is pptd. from H₂O as a gelatinous mass by addn. of EtOH. When dried it decomps. 310° without melting. It could not be obtained cryst. The ratio of amipo N

to total N is 1:10 and an ester group is still present. Hydrolysis with 25% H_2SO_4 gives β -alanine quant. without splitting off NH_3 . The substance is, probably the ester of a β -alanine polypeptide. A. W. DOX

Configurational relationship of methylbutylcarbinol and of 2-hydroxycaproic acid to lactic acid. With a note on the relationship of chemical structure to optical activity. P. A. LEVENE AND H. L. HALLER. Rockefeller Inst. J. Biol. Chem. 79, 475-88(1928).—By the following set of reactions:

the configurational relationship of 2-hydroxycaproic acid (I), to hexanol (II), was detd. The relation of the latter to 4-hydroxyvaleric acid (III), was detd. by the following set of reactions.

Since the relationship of III to lactic acid is known, the relationship of the latter to I and II was thus detd. A summary of the observations on the configurational relationship of the carbinols is given and the law enunciated by Guye [*Compt. rend.* 110, 714 (1890); 116, 1378, 1451(1893)] is found to hold for these substances. The relative effects of the mass and polarity of a group on the direction of rotation is discussed. In addn. to the compds. listed above, hexylenebis- α -naphthyl carbamate, hexan-1-ol-2-one and hexyl- α -naphthyl carbamate were also prepd. ARTHUR GROLLMAN

Catalytic studies on acetoacetic ester. F. O. RICE AND JOSEPH J. SULLIVAN. Johns Hopkins Univ. J. Am. Chem. Soc. 50, 3048-55(1928).—By the distn. of $\text{AcCH}_2\text{CO}_2\text{Et}$ in high vacuum and with special precautions to prevent contamination of the ester, samples were obtained in which the rate of change of the enolic form was over 10 times slower than the (calcd.) best values previously reported; with a sample contg. 38.4% enol (initial) the value of k_1 was 0.0014. Attempts to add substances to the ester which would stabilize it met with no success; the ratio k_2/k_1 (k_2 , rate after addn. of catalyst, k_1 , rate before addn.) was detd. for the following substances in the concn. (concn. $\times 10^{-3}$) given: piperidine, 4, 11,400; NH_3 , 4, 4000; $\text{C}_6\text{H}_5\text{N}$, 4, 264; quinoline, 4, 17; Br, >1300; AcCl , 4, 157; $\text{C}_6\text{H}_5(\text{CO})_2\text{O}$, 40, 6; $(\text{CO}_2\text{H})_2$, 1, 3.2; H_2O , 100, 1; dehydracetic acid, 4, 36; residue, 4, 3. The mean temp. coeff. of the rate of change of the liquid ester, k_{35}/k_{25} was found to be 5.6, from which the heat of activation is calcd. to be 31,200. C. J. WEST

Attempts to synthesize norpinic acid. GEORGE R. CLEMO AND KENNETH N. WELCH. Armstrong College. J. Chem. Soc. 1928, 2621-8.—The 1st attempt consisted in the reaction of $\text{Me}_2\text{C:CO}$ with maleic or fumaric ester, which gave only polymerized $\text{Me}_2\text{C:CO}$ and unchanged ester; likewise condensation could not be effected between $\text{Me}_2\text{CBrCOBr}$ and $(\text{HO}_2\text{C})_2\text{CNaCH}(\text{CO}_2\text{H})_2$. The prepn. of $(\text{EtO}_2\text{C})\text{CMe}_2\text{CH}(\text{CO}_2\text{Et})\text{CH}_2\text{CO}_2\text{Et}$ was then investigated with a view of carrying out the Dieckmann reaction on it to give $\text{Me}_2\text{C.CO.CH}(\text{CO}_2\text{Et}).\text{CHCO}_2\text{Et}$; $\text{Me}_2\text{C}(\text{OH})\text{CN}$ was con-

densed with $\text{CNCHNaCO}_2\text{Et}$ and the resulting product refluxed with $\text{BrCH}_2\text{CO}_2\text{Et}$, but the yield of the ester and acid was so poor that the expt. was discontinued. Heating $\text{CH}_2(\text{CO}_2\text{Et})_2$ (130 g.), 120 g. Ac_2O and 8 g. ZnCl_2 in 110 g. Me_2CO in sealed tubes 80 hrs. in the H_2O bath gives 90 g. $\text{Me}_2\text{CCH}(\text{CO}_2\text{Et})_2$, b_{14} 116-20°; with $\text{CHNa}(\text{CO}_2\text{Et})_2$, there results 10% of $\text{Me}_2\text{C}[\text{CH}(\text{CO}_2\text{Et})_2]_2$, b_1 155°; however, the Na deriv. with CH_2I_2 did not yield the expected cyclobutane deriv. The attempt to condense $\text{MeOCH}_2\text{CH}(\text{CO}_2\text{Et})_2$ with $\text{Me}_2\text{CCH}(\text{CO}_2\text{Et})_2$ to form $(\text{EtO}_2\text{C})_2\text{CHCMe}_2\text{C}(\text{CO}_2\text{Et})_2\text{CH}_3\text{OMe}$ failed. Condensation of $(\text{EtO}_2\text{C})_2\text{CNaCH:C}(\text{CO}_2\text{Et})_2$ with AcCl gave an *O*-Ac deriv., which,

on distn., gives Et ethoxy- α -pyrone dicarboxylate. In the action of Me_2CHI there results, in addn. to the trimesic ester, a considerable quantity of $\text{CH}_2(\text{CO}_2\text{Et})_2$. Et α -acetylglutarate (I) is obtained in 70% yields by refluxing 6 g. Na in 150 cc. EtOH, 33 g. $\text{AcCH}_2\text{CO}_2\text{Et}$ and 35 g. $\text{BrCH}_2\text{CH}_2\text{CO}_2\text{Et}$ for 3 hrs. I does not react with MeMgI . I (11.5 g.), shaken with 15 cc. H_2O and 2.5 g. CaCO_3 and treated dropwise with Br (2.7 cc. during 1 week) gives 13 g. α -Br deriv. (II), b_p 162–5°, which gives no color with FeCl_3 . With MeMgI II is reduced to I. The α -Me deriv. of I reacts with MeMgI to give Et α -methylglutarate. I contg. a little I, treated with NH_3 for 4 days, gives Et α -[α' -aminoethylidene]glutarate, m. 37°; heating at 190–220° splits off EtOH, giving the lactam, $\text{C}_8\text{H}_{11}\text{O}_3\text{N}$, m. 156°. Heating I with PhNH_2 and a trace of I gives CO-(NHPh) $_2$. I (4.7 g.) in 2.4 g. KOH and 9 cc. H_2O , kept 24 hrs., then treated with 30 cc. H_2O , 3 cc. AcOH and ice and then PhN_2Cl from 2 g. PhNH_2 , gives 80% of α -carboxypentane- γ,δ -dione γ -phenylhydrazone (γ,δ -diketohexoic acid γ -phenylhydrazone), pale yellow, m. 178°. I and PhNHNH_2 in AcOH give Et 1-phenyl-3-methyl-5-pyrazolone-4- β -propionate, pale yellow oil, b_p 215°.

C. J. WEST

The structural formula of bixin. I. J. RINKES. Chem. Lab., Amstelveensche Weg 1090, Amsterdam. *Rec. trav. chim.* 47, 934 (1928).—Kuhn and Winterstein have put forward the formula $\text{MeO}_2\text{CCH:CHCMe:CHCH:CHCMe:CHCH:CHCMe:CHCH:CHCMe:CHCO}_2\text{H}$ for bixin (*C. A.* 22, 2950). This formula is in accordance with the formation of AcCHO and $\text{AcCH:CHCO}_2\text{Me}$ on ozonization. In the same way R. previously had obtained from methylbixin the Me ester of an aldehydic acid, which on oxidation, sapon. and hydrogenation gave β -methyladipic acid (*C. A.* 12, 472), while according to the formula of K. and W. α -methyladipic acid was to be expected.

C. F. VAN DUIN

Bromination of tetraethyldicarboxylglutaconate and the constitution of the glutamic acids. YOSHIYUKI URUSHIBARA. Tokyo Imperial Univ. *Bull. Chem. Soc. Japan* 3, 200–7 (1928).—In the action of Br on tetra-Et dicarboxylglutaconate, tetra-Et α -bromodicarboxylglutaconate is obtained as final product. When the latter is saponified in the presence of HCl, the reaction product is α -chloroglutaconic acid. It is concluded that in the sapon. of a deriv. of glutamic acid, the constitution of the reaction product cannot be deduced from that of the starting substance. Uncertainty in Thorpe's theory of the normal form (*J. Chem. Soc.* 87, 1669 (1905)) is pointed out. A. L. H.

Walden inversion. HANS N. K. RØRDAM. Polytechnic Inst., Copenhagen. *J. Chem. Soc.* 1928, 2447–53.—A theory to account for the Walden inversion is proposed in which it is assumed that whether inversion takes place or not depends upon whether the atom, ion or radical X which enters the mol. instead of the atom or radical which is split off, is able to do so while another radical is oscillating from 1 position to another in reference to the plane formed by the other radicals and the C atom. A quant. theory may be derived based on the time of oscillation θ of the mol., the concns. and the activity conditions in the soln. Of these factors nothing is known of the time of oscillation and very little about the activity coeffs. in such high concns. as are usually employed in researches on this subject. However, a formula is developed for n , the fraction of the reaction product which retains its original configuration, and applied to certain data reported by Holmberg.

C. J. WEST

Thiocyanoacetone, its isomers and polymers. A. HANTZSCH, WITH H. SCHWANE-BERG. *Ber.* 61B, 1776–88 (1928).—Reply to Tcherniac (*C. A.* 22, 2146). The following expts. further confirm H.'s observations or disprove T.'s statements. On testing Arapides' statement that "the oily thiocyanacetone (I) even in H_2O slowly changes into the cryst. hydroxythiazole, but most rapidly when it is heated in H_2O with a little dil. HCl on the H_2O bath," it was found that in pure H_2O , I is not appreciably changed in several days but on addn. of HCl and heating quickly isomerizes. The $\text{MeCOCH}_2\text{Cl-Ba(SCN)}_2$ method of prepg. I gives, when the crude product is allowed to stand about 5 days in *vacuo* over H_2SO_4 , a 95% prepn. still contg. a little Cl but sufficiently pure for practical purposes. I and MeNH_2 in cold Et_2O react without resinification, giving first about 80% of the addn. product MeCOCHSC(NHMe):NH , yellow, m. 77°, whose anhydridization to methylaminomethylthiazole (II) takes place even at room temp. in a few hrs., at once on fusing, although pure II can hardly be obtained in this way because of resinification; the II is obtained perfectly smoothly, however, by boiling the addn. product about 20 min. in dil. HCl; it is faintly yellow and non-hygroscopic and m. 70°. I and NH_3 do not react as smoothly to form aminomethylthiazole (III), which is obtained as a brown oil solidifying in *vacuo* over H_2SO_4 ; its Ac deriv., m. 134°. III with AgNO_3 in H_2O yields an addn. product $2\text{C}_4\text{H}_6\text{N}_2\text{S}\cdot\text{AgNO}_3$, which can be recrystd. from alc. but is completely decompd. with sepn. of Ag_2S , by boiling H_2O . The two N-Me compds. derived from the tautomeric iminothiazoline form of III give both NH_3

and MeNH_2 with fuming HCl at 220° , and not, as stated by their discoverer, Traumann, only NH_3 in the 1 case and only MeNH_2 in the other. T.'s alleged "tetramol. "isomethyl-rhodime" is in fact trimol. (mol. wt. in freezing PhOH 329-35) and is really triacetylthiocyanuric acid, $(\text{MeCOCH}_2)_3(\text{SCN})_3$, for it forms a bisphenylhydrazone, turns brown in the air, a bis-*p*-tolylhydrazone, a semicarbazone and a dioxime: C. A. R.

Bromophosgene. II. Its preparation and properties. HANS-JOACHIM SCHUMACHER AND SAM LENHER. Univ. Berlin. *Ber.* 61B, 1671-5(1928); cf. C. A. 22, 3566.— COBr_2 was prep'd. essentially according to v. Barta (*Ann.* 345, 335(1906)). It has d_{15} 252 and a characteristic sweetish unpleasant odor by which traces of COBr_2 can be detected. Its physiol. effects (studied by Kraja) are the same as those of COCl_2 ; (no direct comparison with COCl_2 was made but judging from the literature on COCl_2 the action of COBr_2 is of the same order of magnitude). H_2O and steam hydrolyze COBr_2 to CO_2 and HBr but considerably more slowly than COCl_2 ; with alkalis, however, it rapidly reacts to form the carbonate and bromide. The vapor-pressure curve of pure COBr_2 , from -50° to 25° , was det'd. with a sensitive Bodenstein quartz manometer. Calcd. from this curve, $Q_m = 7200$ cal. The Trouton rule holds well ($Q_m/T_m = 21.6$). The thermal equil. lies far towards the side of decompn. even at room temp. (about 10% COBr_2 calcd. on the basis of the Br present, at 0.25 atm. Br_2 and 0.75 atm. CO). The velocity of formation from CO and Br_2 is very small at room temp. and weeks are required for the establishment of equil. Pure COBr_2 is stable towards thermal influences; up to 200° the decompn. is hardly measurable; at higher temps. it proceeds on the wall of the vessel as a reaction of the 1st order. Impurities, especially org. substances, may catalyze the decompn. extraordinarily. C. A. R.

Iminodicarboxylic acids and nitrilotricarboxylic acids. G. L. STADNIKOV AND N. TROV. Torf-Institut Moscow. *Ber.* 61B, 1788-9(1928).—It had already been shown that the stability of derivs. of iminodicarboxylic acids decreases with increasing mol. wt.; further to test this point, $\text{PhCH}(\text{CO}_2\text{H})\text{N}(\text{CHMeCO}_2\text{H})\text{CHMeCO}_2\text{H}$ (I) and $\text{PhCH}.\text{CO}.\text{O}.\text{CO}.\text{CMe}_2.\text{NCMe}_2\text{CO}_2\text{H}$ (II) were heated with conc'd. HCl at 160° ;

both break down to $\text{PhNHCH}_2\text{CO}_2\text{H}$, showing that not only the original I and II but the intermediate $\text{PhCH}(\text{CO}_2\text{H})\text{NHCHMeCO}_2\text{H}$ and $\text{PhCH}(\text{CO}_2\text{H})\text{NHCMe}_2\text{CO}_2\text{H}$ are unstable under these conditions. I m. 201° (decompn.). II m. 187° (decompn.). C. A. R.

Acetylmonoses. V. The rates of hydrolysis of tetraacetylmethylmannosides and of triacetylmethylxylosides. P. A. LEVENE AND M. L. WOLFROM. Rockefeller Inst. *J. Biol. Chem.* 79, 471-4(1928); cf. C. A. 22, 3633.—The rates of hydrolysis of the α -, β - and γ -forms of tetraacetylmethyl-*d*-mannosides and the α - and β -forms of the triacetate of Me *d*-lyxoside were det'd. The γ -forms of these compds. were hydrolyzed to sugars while the others underwent little hydrolysis. The equality in the rate of hydrolysis of the α - and β -forms of the tetraacetylmethylmannoside shows that they both possess the $\langle 1, 5 \rangle$ structure. Whether the γ -form has the $\langle 1, 3 \rangle$ or the $\langle 1, 4 \rangle$ lactal structure, cannot be concluded from these results. ARTHUR GROLLMAN

Monoacetone- γ -methylglucoside. P. A. LEVENE AND G. M. MEYER. Rockefeller Inst. *J. Biol. Chem.* 79, 357-62(1928).—The acetonization of α -Me $\langle 1, 5 \rangle$ glucoside was attempted by the previously described method (C. A. 22, 3634). The reaction lead to the elimination of the Me group with the formation of diacetoneglucose. When γ -Me glucoside was treated with acetone in the presence of anhyd. CuSO_4 , 5,6-acetone-methyl- $\langle 1, 4 \rangle$ glucoside was formed. It $b_{0.1}$ 148° , is sol. in H_2O , alc., ether and acetone and is hydrolyzed by 0.1 *N* HCl ; $[\alpha]_D^{25}$ 36.4° (MeOH). By methylation with Ag_2O and MeI, 2,3-dimethyl-5,6-acetonemethyl- $\langle 1, 4 \rangle$ glucoside was formed. It $b_{0.1}$ 105° , $[\alpha]_D^{25}$ 3.76° (MeOH). By following the procedure of Macdonald (C. A. 8, 907) a less pure and uniform product was obtained. ARTHUR GROLLMAN

Preparation of acetone cyanohydrin. KENNETH N. WELCH AND GEORGE R. CLEMO. Armstrong College. *J. Chem. Soc.* 1928, 2629.— Me_2CO (29 g.) added to 31 g. KCN in 100 cc. H_2O and slowly treated with 167 g. 30% H_2SO_4 by wt., the temp. being kept below 20° by the addn. of ice, which also, by dilg. the soln., prevents it from becoming unstirrable on account of the sepn. of KHSO_4 , gives 32 g. $\text{Me}_2\text{C}(\text{OH})\text{CN}$, b_{15} 81° . C. J. WEST

Acetone compounds of the sugars and their transformation products. XII. Shifting of the oxygen bridge by the action of hydrogen bromide-acetic acid on acyl derivatives of monoacetoneglucose. HEINZ OHLE AND HEINZ ERLBACH. Univ. Berlin. *Ber.* 61B, 1870-5(1928); cf. C. A. 22, 3140.—It had been found that when 6-benzoyl-

monoacetoneglucose is treated with HBr-AcOH the O bridge is shifted, a pyroid 6-benzoyltriacyl- β -methylglucoside being obtained from the original furoid deriv. The conclusion that this ring isomerization is general for all monoacetoneglucose derivs. in which the 5-HO group is free has been further tested on 3-*p*-toluenesulfonylmonoacetoneglucose (I), which with HBr-AcOH gives a 3-toluenesulfonyltriacylglucosyl 1-bromide (II) identical with a product obtained by Freudenberg and Ivers from 3-*p*-toluenesulfonyldiacetoneglucose. II must therefore have a 1,5-O bridge. On the other hand, 3-*p*-toluenesulfonyl-5,6-diacetylmonoacetoneglucose (III), with an Ac residue on the 5-HO group, would be expected to yield an isomer (IV) of II still contg. the same furoid structure as the original III and as a matter of fact the product obtained differs from II in m. p. and rotation and the corresponding 3-*p*-toluenesulfonyltriacyl- β -methylglucoside (V) and -glucose (VI) also differ from the analogous compds. obtained from I. These results further show that in the treatment of I with HBr-AcOH acetylation of the free HO groups proceeds much more slowly than the formation of the new type of glucose, and as the Me_2CO residue is split off very rapidly it must be assumed that 3-*p*-toluenesulfonylglucose <1,4> or the corresponding glucosyl 1-bromide is the 1st intermediate product and establishes an equil. with the other forms possible under the conditions of the expt., these various forms then undergoing acetylation insofar as they do not take part in other side reactions. This equil. will depend on (1) the concn. of the sugar components, (2) their configuration and (3) the nature, no. and position of the characteristic substituents on the HO groups, the reaction thus affording a method of comparing the relative stability of the different ring structures of a sugar and its derivs. If a Br deriv. crystals out from the HBr-AcOH , no conclusion can be drawn as to the relative stability of its ring structure, of course, but if nothing crystals out all the components of the equil. mixt. can be pptd. out by a liquid in which they are all insol. (H_2O has hitherto always been used) and their relative stabilities detd. by measuring the relative proportions in which they are present in the ppt. In most cases it will hardly be possible to do more than isolate the compd. present in largest quantity and even this is sometimes impracticable because of the instability of the Br compds., which greatly limits the choice of possible solvents. It is advisable, therefore, immediately to convert the reaction mixt. into the corresponding Me glucosides. A special advantage of this method is that only the α -glucosyl bromides are formed and these yield exclusively the β -Me glucosides, thus greatly facilitating the sepn. of the ring isomers. As thus far developed, however, the method has one great drawback—the removal of the HBr and AcOH with H_2O . The Br derivs. as a rule tenaciously retain traces of moisture, which vigorously catalyzes their decompn. A method of working up the HBr-AcOH solns. without using H_2O is being sought. III, from I and Ac_2O in $\text{C}_6\text{H}_5\text{N}$ at 36° , m. $85-6^\circ$, $[\alpha]_D^{20} -19.96^\circ$ (CHCl_3 , c 5.60) (in the 1st prepn. there was obtained a form m. 78.5° , $[\alpha]_D^{20} -16.17^\circ$ (CHCl_3 , c 4.886), which in a desiccator slowly changed into the $85-6^\circ$ form and could not again be obtained in subsequent preps.); boiling alc. KOH sapon. it to monoacetoneglucose. 3-*p*-Toluenesulfonyl-2,5,6-triacyl- β -glucosyl 1-bromide (IV) (1.3 g. from 10 g. III), begins to darken 115° , sinters about 135° , m. 140° to a black liquid, $[\alpha]_D^{20} 198.9^\circ$ (CHCl_3 , c 4.056). V (0.35 g. from 0.7 g. IV with Ag_2CO_3 in MeOH), m. 128° (mixed m. p. with Freudenberg and Ivers' compd. (m. 134°) $115-26^\circ$), $[\alpha]_D^{20} -64.25^\circ$ (CHCl_3 , c 1.323). VI, from IV recrystd. from too much Me_2CO , m. 129.5° , $[\alpha]_D^{20}$ (CHCl_3 , c 4.748) 62.97° (initial), 40.65° (at equil.). The isomeric 3-*p*-toluene-2,4,6-triacylglucose <1,5>, from II with moist Ag_2CO_3 in Me_2CO , m. $178.5-9^\circ$, $[\alpha]_D^{20}$ (CHCl_3 , c 4.662) 40.11° (initial), 51.48° (final). XIII. Behavior of completely acylated derivatives of monoacetoneglucose towards hydrogen bromide-acetic acid. HEINZ OHLE, HEINZ ERLBACH AND KURT VOGL. *Ibid* 1875-85.—As had already been pointed out, the reaction of monoacetoneglucose derivs. with HBr-AcOH is not limited to the formation of acyl derivs. of ring-isomeric glucosyl 1-bromides but is complicated by a side reaction giving compds. with more firmly bound Br (probably on C atom 4); parallel with this firmer binding of the Br there appears the characteristic color reaction, which is doubtless a halochromism phenomenon and can be ascribed only to further transformation products of these 4-Br compds. It had not been found possible hitherto to isolate any of these Br compds., probably because of their instability, but it was hoped that this might be accomplished by using the completely acylated monoacetoneglucoses where, because of the absence of free HO groups, the O bridge cannot be shifted and the reaction is by that much simplified. This hope too has thus far not been fulfilled but there was observed another effect which apparently depends on the nature and the position of the acyl groups. Triacylmonoacetoneglucose, as already shown, behaves towards

HBr-AcOH entirely like the partially acylated it shows the characteristic play of colors from yellow through red and violet and gives large quantities of products with firmly bound Br. S. The same is true of the tri-Bz deriv. As soon, however, as a p -MeC₆H₄SO₂ group is introduced, the picture changes. 3- p -Toluenesulfonyl-5,6-diacetylmonoacetoneglucose (above) no longer shows the characteristic play of colors although the color of the soln. darkens to brown-red. The HBr-AcOH soln. of the 5,6-di-Bz analog remains light yellow for days, and the resulting 2-acetyl-3- p -toluenesulfonyl-5,6-dibenzoylglucosyl 1-bromide (I) crystals out directly; it is so sensitive, however, that it has not yet been possible to purify it and when it is converted into the Me glucoside it may easily give mixts. of different glucosides. The solns. of 3,5-di- p -toluenesulfonyl-6-benzoyl- and tri- p -toluenesulfonylmonoacetoneglucose in HBr-AcOH likewise remain light yellow, and of the products, which crystal out, the 2-acetyl-3,5-di- p -toluenesulfonyl-6-benzoylglucosyl 1-bromide<1,4> (II) is the more stable. The 2-acetyl-3,5,6-tri- p -toluenesulfonylglucosyl 1-bromide<1,4> (III) forms a stable mol. compd. with 1 mol. C₆H₆. The conversion of these compds. into the corresponding β -Me glucosides and tetraacylglucoses offers no difficulties. On the other hand the 5- p -toluenesulfonyl-6-benzoyl- and 5,6-di- p -toluenesulfonylmonoacetoneglucoses give an intense red color and large quantities of products with firmly bound Br which, however, could not be isolated in crystal form. The acyl derivs. of monoacetoneglucose can therefore be classified in 2 groups as regards their reaction with HBr-AcOH, i. e., by suitable esterification the furoid structure of glucose derivs. can be so stabilized that it remains completely unaltered under conditions under which normally it is decomposed. As a no. of corresponding pairs of furoid sugars were obtained in the course of this investigation the point was tested whether the principle of optical superposition can be applied to them. Below are the values for $[M]_{Br} - [M]_{Me}$ (difference between the mol. rotations of the α -glucosyl 1-bromide and β -Me glucoside) for the various glucoses: 2,3,4,6-tetraacetyl, 88,500; 2,3,4-triacetyl-6-bromo, 88,600; 2,3,4,6-tetra-benzoyl, 45,000; 3- p -toluenesulfonyl-2,4,6-triacetyl, 95,200; 3- p -toluenesulfonyl-2,5,6-triacetyl, 134,500; 2-acetyl-3,5-di- p -toluenesulfonyl-6-benzoyl, 112,000; 2-acetyl-3,5,6-tri- p -toluenesulfonyl, 100,700. It is evident that the law of optical superposition, in the form here developed, does not hold. This is to be ascribed in the 1st place to the fact that the values for A_{Br} and A_{Me} in the equations $M_{Br} = A_{Br} + C$ and $M_{Me} = -A_{Me} + C$ are not const. in the different acylated glucosyl bromides and Me glucosides, and, in the 2nd place, that the value of C is not the same for the bromide and glucoside of any given pair. The applicability of the law is therefore limited to compds. of the same constitution, i. e., those differing only sterically. Another noteworthy regularity observed in the tetraacyl derivs. of glucose contg. a free 1-HO group is that whereas in the pyroid forms the β -derivs. have the greater crystal. power and the lesser soly., in the furoid forms it is the α -derivs. which have these properties. Tri- p -toluenesulfonylmonoacetone- d -glucose (2.4 g. from 9 g. monoacetoneglucose in C₆H₅N with 3 mols. MeC₆H₄SO₂Cl in CHCl₃ at 36°, m. 95-6°, $[\alpha]_D^{19} -5.15^\circ$ (CHCl₃, c 12.12). III (yield, 77%), crystals with 1 mol. C₆H₆, m. 106.5-8° (decompn.), $[\alpha]_D^{20} 114.5^\circ$ (CHCl₃, c 4.928); by pptn. from C₆H₆ with much petroleum ether is obtained an almost pure solvent-free product, m. 124-5°, $[\alpha]_D^{19} 124.5^\circ$ (c 3.020). β -Methylglucoside, from III in MeOH with freshly pptd., dried Ag₂CO₃ at room temp., m. 129.5°, $[\alpha]_D^{20} -8.9^\circ$ (CHCl₃, c 6.210). Glucose (1.15 g. from 3 g. of the tritoluenesulfonylmonoacetoneglucose treated with HBr-AcOH, stirred into ice water, filtered, pressed out and shaken, while still moist, in Me₂CO with Ag₂CO₃), m. 117-8°, $[\alpha]_D^{20}$ (CHCl₃, c 4.972) 51.09° (initial), 37.2° (final). II (4.8 g. from 6 g. di- p -toluenesulfonylbenzoylmonoacetoneglucose), m. 159-60°, $[\alpha]_D^{20} 156.6^\circ$ (CHCl₃, c 3.996); 2 g. yields 0.75 g. of the β -methylglucoside, m. 105°, $[\alpha]_D^{20} 4.16$ (CHCl₃, c 3.850); of this 3 g. gives 1.4 g. of the glucose, m. 139°, $[\alpha]_D^{20}$ (CHCl₃, c 4.986) 69.2° (initial), 46.33° (final). 2-Acetyl-3- p -toluenesulfonyl-5,6-dibenzoyl- β -methyl- d -glucoside<1,4> (yield, 21%), m. 132.5°, $[\alpha]_D^{20} -74.3^\circ$ (CHCl₃, c 4.266), does not reduce Fehling soln. after sapon. with aq. alc. NaOH. Glucose (1.2 g. from 2.6 g. toluenesulfonyldibenzoylmonoacetoneglucose), m. 122°, $[\alpha]_D^{20}$ (CHCl₃, c 3.118) 3.55° (initial), -20.52° (final).

C. A. R.

A new unsaturated anhydroglucose. B. HELFERICH AND E. HIMMEN. Univ. Greifswald. Ber. 61B, 1825-35(1928).—The acetylated glucose or Me glucoside 6-halohydrins react with certain Ag salts under definite conditions in an unexpected manner. With Ag₂SO₄ or com. AgI in MeOH, in MeCN, in C₆H₅N more or less rapidly, the bromides and iodides split off the halogen acid more or less completely at room or

higher temp. The best yields, after several hrs.' shaking at room temp., are obtained from the 6-iodohydrin, in abs. C_6H_5N with dried "Ag fluoride" which, however, still always contains considerable quantities of the subfluoride and probably also of Ag_2O . The fact that H_2O in relatively small quantities, without pptg. out the iodide, interferes markedly with the reaction indicates that C_6H_5N complexes play an important role as intermediate products. The resulting substances have a double bond, qual. detected by the decolorization of Br in AcOH or $CHCl_3$. Assuming that there is no shifting of the double bond in the reaction or in the isolation of the products, the double bond can be only between C atoms 5 and 6 and the products must have the structure $CH_2:C.CH(OAc).CH(OAc).CH(OAc).CH(OR).Q$ (I, R = Ac or Me). The name

glucoseenes, glucoseenides, is suggested for them. To establish with certainty the position of the double bond, β -triacetylmethylglucoseenide (II) was satd. with Cl, which gave a cryst. *dichloride* (III). Furthermore, the α -isomer (IV) of II with O_3 and reduction of the ozonide with Zn dust gives in good yield a methyl-*d*-xyluronic acid triacetate (V). The double bond in the I is also readily satd. with H and Pt sponge in AcOH. Sapon. of the II and IV to the free β - and α -Me glucoseenides (VI and VII) was effected by a modification of the Zemplén method. Neither VI nor VII reduces Fehling soln. Towards acids they are very sensitive. Soln. in 2 N HCl, folw. by addn. of alkali in excess in a few sec., suffices to split off the MeO group with formation of the free *glucoseene* (VIII), which reduces Fehling soln. at room temp. All reactions of VI and VII in acid soln. are therefore really reactions of the free VIII. VIII has thus far been obtained only in amorphous form and in soln. It is very reactive. Opening of the O ring yields a hydroxyenol aldehyde, $CH_2:C(OH)CH(OH)CH(OH)CH(OH)CHO$, which changes by ketone rearrangement into a methylketoaldopentose, $MeCOCH(OH)CH(OH)CH(OH)CHO$. It forms difficultly sol. compds. with $PhNHNH_2$ and is turned yellow by NaOH. With phloroglucinol-HCl VI gives rapidly a red color and, after a time, a dark voluminous ppt., evidently a condensation product of the VIII with the phenol. Other phenols (orcinol, pyrogallol) likewise give colors and condensation products; $PhNH_2$ in H_2SO_4 gives a yellow color, $m-O_2NC_6H_4NH_2$ in HCl a yellow color gradually changing to orange-red. These colors are very similar to those ascribed to certain wood constituents and in part to lignin itself. α -Tetraacetyl-*d*-glucose 6-bromohydrin (4.6 g. from 10 g. acetodibromoglucose with Ac_2O and concd. H_2SO_4 at 125°), m. $172-3^\circ$ (all m. ps. cor.), $[\alpha]_D^{25}$ 108.5° ($AcOEt$), $[\alpha]_D^{24}$ 110.6° ($CHCl_3$). 6-Iodohydrin (4.5 g. from 4.6 g. of the Br compd. with NaI in Me_2CO at 100°), m. 182° , $[\alpha]_D^{22}$ 101.8° ($CHCl_3$), slowly reduces boiling Fehling soln. α -Tetraacetyl-*d*-glucoseene (0.3 g. from 1.2 g. of the iodohydrin), m. $115-6^\circ$, $[\alpha]_D^{23}$ $108.7-110.9^\circ$ ($CHCl_3$). β -Isomer, m. 119° , $[\alpha]_D^{22}$ -35.0° ($CHCl_3$). Triacetyl- α -methyl-*d*-glucoside 6-*p*-toluenesulfonate (41 g. from 30 g. 2,3,4-triacetyl- α -methyl-*d*-glucoside in C_6H_5N with $p-MeC_6H_4SO_2Cl$ at room temp.), m. $77-8.5^\circ$, $[\alpha]_D^{24}$ 126.3° ($CHCl_3$), does not reduce Fehling soln. even on boiling; 40 g. with NaI in Me_2CO at 130° gives 29.6 g. of the 6-iodohydrin, m. $150-1^\circ$, $[\alpha]_D^{24}$ $116.1-116.3^\circ$ ($CHCl_3$) IV, seps. with MeOH of crystn., m. $100-1^\circ$, $[\alpha]_D^{23}$ (solvated) 116.9° , $[\alpha]_D^{18}$ (solvent-free) 123.8° ($CHCl_3$); from these values, the content of MeOH is calcd. to be 0.5 mol. IV does not reduce Fehling soln. even on boiling. VII is very hygroscopic and no good solvent for it has yet been found. V, m. turbid $83-4^\circ$, clear 85° , $[\alpha]_D^{18}$ 92.0° ($CHCl_3$), slowly sol. in concd. NaOH, apparently with complete alteration, for the soln. does not reduce Fehling soln.; with dil. NaOH (about 2 N) it first becomes red and then dissolves to a yellow liquid which strongly reduces boiling Fehling soln. II (29 g. from 47 g. triacetyl- β -methyl-*d*-glucoside 6-iodohydrin, m. $115-6^\circ$, $[\alpha]_D$ 13.4° , obtained quant. from the Br compd. with NaI in Me_2CO), m. $92-3^\circ$, $[\alpha]_D^{20}$ -34.8° ($CHCl_3$). III, m. $129.5-32^\circ$, reduces hot Fehling soln., loses HCl in boiling H_2O . VI (6.25 g. from 10 g. II in $CHCl_3$ at -20° with Na in MeOH), m. $109-10^\circ$, $[\alpha]_D^{15}$ -115.5° (H_2O), has an insipid, very faintly sweetish taste with somewhat bitter after-taste, is easily reacylated with $Ac_2O-C_6H_5N$ at 0° .

C. A. R.

Halohydrins of gentiobiose and glucose. BURCKHARDT HELFERICH AND HERBERT COLLATZ. Univ. Greifswald. *Ber.* 61B, 1640-6(1928).—Outside of acetohalogen-sugars of the reducing saccharides which have the halogen on the 1-C atom, only few halohydrins of disaccharides were known. A gentiobiose 6'-bromohydrin (I) and its derivs. have now been made available by the synthesis of gentiobiose. If 1,2,3,4- β -tetraacetyl-*d*-glucose is coupled with acetodibromoglucose (instead of acetobromo-

glucose) there is readily obtained and in good yield a *heptaacetylgentiobiose 6'-bromohydrin* (II) which can be saponified to the free I, although the Zemplén sapon. method must be somewhat modified, as the presence of NaOAc prevents the crystn. of the I even from org. solvents. But if titrated NaOMe is used and after the reaction is complete a quantity of H_2SO_4 equiv. to the NaOMe (or a trace less) is added, the resulting Na_2SO_4 , being insol. in org. solvents, is more easily and completely removed than NaOAc from the sugar. From II is easily obtained an *acetodibromogentiobiose* (III) and from this, in turn, a *β -hexaacetylgentiobiose 6'-bromohydrin* (IV). For purposes of comparison and to study the properties of these compds. on cheaper material, several glucose halohydrins have also been prepd. II (9.5 g. from 27 g. acetodibromoglucose and 81 g. tetraacetylglucose in CHCl_3 with 22 g. Ag_2O ; almost 75% of the tetraacetylglucose used can be recovered), m. 240° (cor.), $[\alpha]_D^{10} 2.15^\circ$, $[\alpha]_D^{17} 2.38^\circ$ (CHCl_3), practically does not reduce Fehling soln. because of its slight soly. in H_2O . I (yield, 78%), sinters about 100° , m. $125-30^\circ$ (decompn.), carbonizes about 150° , slowly loses in wt. over P_2O_5 under 12 mm., has no measurable rotation in H_2O unless borax is added ($[\alpha]_D^{18} -12.8^\circ$ for 0.1278 g. I with 0.1012 g. anhyd. borax in 3.0296 g. H_2O), deliquesces in the air, reduces hot Fehling soln. III (0.55 g. from 1 g. II in cold abs. CHCl_3 with HBr in AcOH), m. about 193° (decompn.), $[\alpha]_D^{18} 108.1^\circ$, $[\alpha]_D^{21} 109.5^\circ$ (CHCl_3), does not reduce boiling Fehling soln. IV (0.6 g. from 0.7 g. III and Ag_2CO_3 in Me_2CO contg. a little H_2O), m. 264° (cor.), $[\alpha]_D^{18} 9.99^\circ$ after 20 min., 41.45° after 24 hrs. ($\text{C}_6\text{H}_5\text{N}$) (by extrapolation, the initial rotation is negative), reduces hot Fehling soln. *β -Tetraacetylglucose 6-iodohydrin* (V) (87% from the bromohydrin and NaI in Me_2CO at 100°), m. 152° (cor.), $[\alpha]_D^{23} 9.12-9.34^\circ$ (CHCl_3), gives no AgBr with AgNO_3 in Me_2CO even on short boiling, reduces hot Fehling soln., yields in CHCl_3 with HBr in cold AcOH 60% of *triacylglucose 1-bromo-6-iodohydrin*, m. $168-77^\circ$ (decompn.), depending on the rate of heating, $[\alpha]_D^{23} 177.7-8.9^\circ$ (CHCl_3), faintly reduces Fehling soln. only after long boiling, gives with Ag_2CO_3 in Me_2CO 79% of the *6-iodohydrin*, m. $159-60^\circ$ (cor.), $[\alpha]_D^{21} 31.25-32.23^\circ$ (CHCl_3), slowly increasing (81.25° and not yet const. after 6 days), reduces boiling Fehling soln. *Aceto-1,6-diiodoglucose* (65% from V in alc. with HI in AcOH), darkens around 130° , decomp. about 150° , $[\alpha]_D^{22} 205.0^\circ$ (CHCl_3), does not reduce Fehling soln., gives AgI with AgNO_3 . C. A. R.

Acetone-sugars. XIII. Hydrolysis of some disaccharides, glucosides and acetone-sugars. KARL FREUDENBERG, WALTER DÜRR AND HEINRICH VON HOCHSTETTER, IN PART WITH H. VON HOVE, W. JACOBI, A. NÖE AND E. GÄRTNER. Univ. Heidelberg. *Ber.* 61B, 1735-43(1928); cf. C. A. 22, 226.—A disaccharide from glucose and galactose was successfully synthesized thanks to the fact that in the intermediate glucosidodi-acetonegalactose HCl splits off the Me_2CO residue much more rapidly than it ruptures the disaccharide union. For the continuation of expts. along this line accurate knowledge of the 2 concurrent reactions was necessary; even for disaccharides and simple glucosides no uniform measurements were available. 1. *Inversion consts. of disaccharides and glucosides.*—Equal vols. of 0.2 N sugar soln. and N H_2SO_4 at 70° ($\pm 0.1^\circ$) were used. The rotations were read at 18° . To det. the end rotation a corresponding mixt. of the monosaccharides resulting from the cleavage was heated under the same conditions. Difficulties were encountered only with turanose because of the instability of the fructose. The trisaccharide melezitose in the same mol. concn. was first inverted at 18° to split off the glucose present in sucrose union and when the rotation, which fell from 4.55° to 3.40° , became const. after 18 hrs., the last value was taken as the initial rotation and the hydrolysis continued at 70° . For comparison was taken a mixt. of 2 mols. glucose and 1 mol. fructose. With monoacetoneglucose, because of the velocity of the reaction, the sugar and acid had to be preheated to 70° before mixing. Below are the av. values for $K \cdot 10^4$: glucosido- β -6-galactose 2.2, cellobiose (glucosido- β -4-glucose) 3.4, turanose (glucosido- α -6-fructose) 4.2, maltose (glucosido- α -4-glucose) 6.0, lactose (galactosido- β -4-glucose) 7.2, galactosido- β -6-galactose 10.2, melibiose (galactosido- α -6-glucose) 5.6, β -Me glucoside 1.7, α -Me glucoside 0.70, β -benzyl glucoside 1.9, β -Ph glucoside 13.7, α -Ph glucoside 37.0, β -Me galactoside 7.5, α -Me galactoside 4.6, 1,2-monoacetoneglucose 3100.0. The hydrolysis of the other acetone-sugars is so rapid that another method had to be used to measure it. 2. *Cleavage of acetone-sugars.*—The acetone-sugar (0.001 mol.) was boiled in 100 cc. of a buffer soln. (pH 3.6-4.4 at 20°) and the Me_2CO distd. into ice-cold H_2O and detd. by Kolthoff's method (Die Massanalyse, Berlin, 1928, p. 431). The boiling soln. was kept at a const. level by dropping in H_2O . Monoacetoneglucose has the smallest const. That of diacetonegalactose is of about the same magnitude; although 2 mols. Me_2CO are split off, the

const. between 15 and 90% cleavage decrease to only $1/2$, i. e. the reaction velocity is very similar for both Me_2CO residues. Monoacetone- α -mannose is hydrolyzed about 10 times more rapidly than the glucose compd. and so is diacetone- α -mannose but here the const. shows a much greater drift than for diacetonegalactose, falling to 0.5 between 20 and 60% cleavage, and it was therefore possible to obtain a monoacetone- α -mannose (as the Ac deriv.); it does not reduce Fehling soln. Diacetoneglucose shows the greatest fall in the const.; the 5,6- Me_2CO residue is split off roughly 40 times more rapidly than the 1,2-residue. At p_H 3.0 (measured in the cold) the most stable acetone-sugars are hydrolyzed in 2 hrs. at 100° and for the others much milder conditions suffice, while the disaccharides and glucosides studied are stable under these conditions. A no. of miscellaneous observations made in connection with the prepn. of the above compds. are reported. Monoacetone-3-benzylglucose diacetate, from the diacetone compd. in AcOH on the H_2O bath or from monoacetoneglucose in boiling dioxan treated with Na, allowed to stand 2 days at 20° , heated 6 hrs. at 70° with PhCH_2Cl , evapd. *in vacuo*, extd. with Et_2O and acetylated in $\text{C}_6\text{H}_5\text{N}$ with Ac_2O , m. $119-9.5^\circ$, $[\alpha]_D -53^\circ$ in $(\text{CH}_2\text{Cl})_2$. Monoacetone-3-methylglucose, from the diacetone compd. allowed to stand 2 days at 20° in AcOH- H_2O (4:1), b₁ $173-5^\circ$; dibenzoate, m. $81-2^\circ$. Triacetylmonoacetone- α -mannose, from diacetone- α -mannose boiled 1.25 hrs. in a biphtalate buffer soln. (p_H 4.4), m. 59° , $[\alpha]_D 49.9^\circ$ in $(\text{CHCl}_3)_2$. The old observation that the formation of diacetoneglucose depends to a large extent on the quality of the Me_2CO is explained by the fact that AcH and acetals accelerate the reaction extraordinarily. For the splitting off of the 5,6- Me_2CO residue in diacetoneglucose AcOH is best. Benzyl ethers of the sugars seem to be very stable towards acids and alkalis but are easily hydrolyzed on hydrogenation with Pt metals and with Na-Hg. A renewed study of F. and Hixon's partly cryst. diacetone- α -mannoside showed that it contains, besides the cryst. part, m. $40-1^\circ$, $[\alpha]_D -42^\circ$ in $(\text{CHCl}_3)_2$, a *d*-rotatory liquid part which, however, could not be freed from the solid form; the highest rotation obtained was 11° . Methylation of diacetone- α -mannose according to Levene and Meyer did not give their product with $[\alpha]_D 23^\circ$ but a mixt. from which were obtained fractions, b₁ $111-5^\circ$, $115-7^\circ$, $117-8^\circ$, $[\alpha]_D 32^\circ$, 19° , 3° , resp. XIV. Syntheses of further di- and trisaccharides from galactose, glucose and mannose. KARL FREUDENBERG, ANTON WOLF, ERICH KNOPF AND SYED H. ZAHEER. *Ibid* 1743-50.—New detns. of the rotation of 6- β -glucosido- β -galactose gave values lower than those obtained before and which are believed to be more nearly correct: $[\alpha]_D^{18} (\text{H}_2\text{O}) 1.6^\circ (\pm 0.5^\circ)$ 10 min. after soln., 13.9° (const.) after 2 days. Heptaacetylcellobiosidodiacetonegalactose (2 g. from 5 g. acetobromocellobiose and diacetonegalactose with Ag_2O in CHCl_3), m. 227° , $[\alpha]_D^{18} -47.1^\circ$ in $(\text{CHCl}_3)_2$ converted by boiling $\text{Ba}(\text{OH})_2$ into the sirupy cellobiosidodiacetonegalactose which with boiling 0.02 *N* H_2SO_4 gives 6- β -cellobiosido- β -galactose, crystals with $2\text{H}_2\text{O}$, $[\alpha]_D^{19} 22.9^\circ$ (H_2O) 10 min. after soln., 9.25° (const.) after 3 hrs. (calcd. for anhyd. form, 24.6° , 9.9° , resp.); osazone, m. 207° (decompn.). Heptaacetylactosidodiacetonegalactose (12 g. from 17 g. acetobromolactose), amorphous; lactosidodiacetonegalactose (4 g. from 12 g. of the Ac compd.), hydrated crystals, m. 117° , $[\alpha]_D^{18} -39.8^\circ$ (H_2O); 6- β -lactosido-galactose (1.5 g. from 3 g. of the Me_2CO compd.), amorphous, $[\alpha]_D^{18} 22.2^\circ$ (H_2O) (osazone, m. 211° (decompn.)). Tetraacetylgalactosidodiacetonegalactose (10 g. from 31 g. acetobromogalactose), m. $101-2^\circ$, $[\alpha]_D^{19} -44.7^\circ$ in $(\text{CHCl}_3)_2$; 6- β -galactosido- β -galactose, $[\alpha]_D^{17} (\text{H}_2\text{O}) 25.1^\circ$ 8 min. after soln., 34.1° (const.) after 48 hrs. (osazone, m. 207° (decompn.)). Diacetone- α -mannose 1-chlorohydrin (9-10 g. from 12 g. diacetone- α -mannose with SOCl_2 in CHCl_3 - $\text{C}_6\text{H}_5\text{N}$), b₁ $112-5^\circ$; 10 g. with diacetonegalactose and Ag_2CO_3 in CCl_4 gives 3 g. diacetone- α -mannosidodiacetonegalactose, oil solidifying to a glassy mass, b₁ $205-10^\circ$, mol. wt. in camphor 505, $[\alpha]_D^{18} -44.6^\circ$ in $(\text{CHCl}_3)_2$; 6- α -mannosido- α -galactose (the configuration of the 1-C atom of the mannose component is unknown), crystals with MeOH of crystn., $[\alpha]_D^{20} (\text{H}_2\text{O}) 142^\circ$ 5 min. after soln., 134° (const.) after 3 hrs. Diacetone- α -mannosidodiacetone- α -mannose (2 g. from 15 g. diacetone- α -mannose 1-chlorohydrin), m. $180-1^\circ$, $[\alpha]_D^{18} 84^\circ$ in $(\text{CHCl}_3)_2$; mannosido-1-mannose, sirup, does not reduce Fehling soln., $[\alpha]_D^{17} 53^\circ$ (H_2O). XV. Attempts to synthesize disaccharides. KARL FREUDENBERG, HANS TORPFFER AND CARL CHR. ANDERSEN. *Ibid* 1750-60.—In all syntheses of disaccharides hitherto carried out, the C:O of the 1 sugar reacts with the end HO group (1 or 6) of the other. Union through a secondary HO group seems to be more difficult. Diacetoneglucose, whose 3-HO group is free, apparently will in no wise react with the halogen deriv. of the monose. Believing this might be because this HO group is in a ring and between two Me_2CO residues, the authors undertook some expts. with

glucose derivs. more loosely constructed but the 1- and 6-HO groups protected, viz. 1,2-monoacetoneglucose 6-bromohydrin (I) and 4,6-benzal- β -methylglucoside (II). Both form disaccharide derivs. with acetobromoglucose (III) and there is no doubt that the method, suitably modified, will lead to the formation of the disaccharides themselves. But it is not an unambiguous, decisive synthesis, for there are 2 secondary HO groups with which the III can react. α -Glucose 6-bromohydrin (IV) was prepd. from its tri-Ac deriv. In its diacetone compd. (V or VI) the Br atom is unusually unreactive and the same is true of the I in the I compd. (VII). If the Br is removed with NaOEt, there is formed, with loss of HBr and Me₂CO, a monoacetoneanhydroglucose which would be expected to have the structure VIII, already adopted, with good reasons, for a different compd. obtained in another way with Ohle, v. Vargha and Erlbach (C. A. 22, 3141). There is no explanation as yet of this fact, nor is one afforded by the observation that I yields the same VIII with Ag₂O. With TIOAc in AcOH-Ac₂O, on the other hand, I gives the known monoacetone-triacetylglucose. I, however, does not react with Ag₂CO₃ in the cold and can therefore be treated with III in the presence of Ag₂CO₃ in indifferent solvents, giving a non-cryst. intermediate product which, however, on the introduction of another Ac group with Ac₂O-C₂H₅N yields a cryst. tetraacetylglucosidomonoacetone-monoacetylglucose 6-bromohydrin, for which the structure IX is given the preference. The hope that the Br atom in this could be replaced by AcO with TIOAc was not fulfilled. Neither in this or in any other way could a cryst., Br-free product be obtained. The corresponding I compd. (X), obtained with KI, yielded with TIOAc in MeOH a cryst. product (XI), which, however, proved to be a tetraacetylglucosidomonoacetone-anhydroglucose. According to Irvine and Scott II, because of the asym. C atom of the

PhCH = residue, exists in 2 forms, m. 161–2° and 148–9°, resp. By a modified method of prepn. the authors obtained 57% of the 161–2° form with only traces of the other. I. and S. have already made it probable that the 2-HO group in II is free. The authors applied their expts. to 3-methylglucose, which is converted by HCl in MeOH into a sirupy mixt. of its α - and β -Me glucosides and this with BzH gives 2 benzal derivs. which on methylation yield 2 benzaldimethylmethylglucosides identical with the methylation product of the 161–2° II and its β -Me isomer, resp., showing that in II and the β -Me compd. the 3-HO group must be free and leaving, as possibilities for III the 5,6- and 4,6-benzal structures; in favor of the latter it might be advanced that the union has the firmness of the original α -Me glucoside<1,5>. The ease with which the PhCH group can be split off by hydrogen is worthy of note. With III, II gives a cryst. tetraacetylglucosidobenzal-[α -methyl]glucoside (XII), yielding successively a cryst. glucosidobenzal-[α -methyl]glucoside (XIII) and a 2- or 3- β -glucosido-[α -methyl]glucoside (XIV), different from Helferich and Becker's synthetic α -Me gentiobioside; it has not been possible to split off the Me group. IV (55% from the tri-Ac deriv. and 5% HBr at room temp.), m. 134° (decompn.), [α]_D¹⁷ (H₂O) 88.9° 10 min. after soln., 48.95° (const.) after 18 hrs. or immediately on addn. of a drop of NH₄OH, gives in C₂H₅N with Ac₂O the tetra-Ac deriv., m. 171°. V (1 g. from 2.5 g. IV in Me₂CO with concd. H₂SO₄), faintly yellow, b₁₋₂ 146°, [α]_D¹⁹ 32.0° (alc.). I, obtained in 1.3 g. yield along with the V, m. 87°, [α]_D²⁰ –13.1° (H₂O), yields with cold Ac₂O-C₂H₅N a diacetate, m.

115°, $[\alpha]_D^{20}$ -7.11° in $(\text{CHCl}_3)_2$. VII, m. 126°, $[\alpha]_D^{18}$ -27.1° (H_2O). IX, m. 161°, $[\alpha]_D^{17}$ -63.6° in $(\text{CHCl}_3)_2$. VII, from V and NaI in Me_2CCl_2 at 100°, b₁₁ 110-20°, m. 58°, $[\alpha]_D^{18}$ 30.9° (alc.). X, m. 136°, $[\alpha]_D^{18}$ -80.8° in $(\text{CHCl}_3)_2$. XI, m. 106°. II was obtained in 23 g. yield from 28 g. α -Me glucoside, anhyd. ZnCl_2 and BzH , the β -Me compd., m. 205°, in 2 g. yield from 4 g. β -Me glucoside. Dimethylbenzal- $[\beta$ -methyl]-glucoside, m. 134°, $[\alpha]_D^{23}$ -61.0° (alc.). Benzal- β -methyl- $[\alpha$ -methyl]glucoside, m. 133°, $[\alpha]_D^{22}$ 49.1° in $(\text{CHCl}_3)_2$; β -compd., m. 164°, $[\alpha]_D^{22}$ -39.1° in $(\text{CHCl}_3)_2$. XII (4.7 g. from 20 g. II), m. 232°, $[\alpha]_D^{21}$ 47° (CHCl_3). XIII, m. 245°, does not reduce Fehling soln. XIV, m. 252° (decompn.), $[\alpha]_D^{18}$ 62.1-62.7° (H_2O), forms no reducing sugar with yeast.

Nomenclature of parent ring systems. AUSTIN M. PATTERSON. Antioch College. *J. Am. Chem. Soc.* 50, 3074-87(1928).—Several general principles are formulated for the correct naming of parent ring systems. The individual classes of ring systems are then considered. The present state of their nomenclature is presented, the more promising methods for forming their names are discussed and some new proposals are submitted.

C. J. WEST

Possibility of ring-chain valency tautomerism and of a type of mobile-hydrogen tautomerism analogous to the Wagner-Meerwein re-arrangement. IV. Substitution reactions of some cyclic derivatives of phorone. CHARLES WM. SHOPPÉE. Univ. of Leeds. *J. Chem. Soc.* 1928, 2360-5; cf. *C. A.* 22, 3636.—Since numerous observations have been made which indicate that the 5-C nucleus possesses remarkable stability such as is sometimes found to be associated with tautomeric complexes, it was decided to study the action of substituting agents on hydroxyphorone and its derivs. in order to det. the conditions under which the nuclear type is preserved. The action of Br in CHCl_3 upon the 5-Ac (I), 5-MeO and 5- $\text{BrC}_6\text{H}_4\text{CH}_2\text{O}$ (II) derivs. of 2,2,3,3-tetramethyl- Δ^4 -cyclopentenone gives bromohydroxyphorone (III), m. 116°. 3,3,4,4-Tetramethylcyclopentenone and Br give a *di*-Br deriv., m. 93°; the 5-MeO deriv. also gives a *di*-Br deriv., m. 99-100°, which gives no color with FeCl_3 and is stable to Br in AcOH and alk. KMnO_4 ; on standing it decomp. with evolution of Br. Quinolinium perbromide (IV) and I give III, but in the presence of 1 mol. quinoline there results the 4-Br deriv. of I, m. 73°. II and IV give the 4-Br deriv. of II, m. 64°, with or without quinoline. Hydroxyphorone and 2,4,6- $\text{Br}_3\text{C}_6\text{H}_2\text{N}_2\text{HSO}_4$ give the crimson 4-[2',4',6'-tribromobenzeneazo]-5-hydroxy-2,2,3,3-tetramethyl- Δ^4 -cyclopentenone, sol. in cold 2 *N* NaOH; the corresponding 4-*p*-carbethoxybenzeneazo deriv., crimson, m. 160° (decompn.), sol. in cold 2 *N* NaOH and upon reduction and hydrolysis yields 2,2,3,3-tetramethylcyclopentylamine.

C. J. WEST

Some 1,2-dialkylcyclopentane derivatives. FRANCIS H. CASE AND E. EMMET REID. Johns Hopkins Univ. *J. Am. Chem. Soc.* 50, 3062-5(1928).—The Na salt from 20.7 g. Na and 140 g. α -carbethoxycyclopentanone in 400 cc. C_6H_6 , treated with 131 g. MeI and refluxed 3 hrs., gives 82% of the α -Me deriv., b₁₇ 106-7°; the α -iso-Pr deriv. is obtained in 59% yield. α -Ethyl- α -carbethoxycyclopentenone (I), b₇ 100°, d₄²⁰ 1.0531, d₄²⁵ 1.0310 (74% yield). Heating 100 g. I, 100 cc. H_2SO_4 and 200 cc. H_2O 5 hrs. gives 39 g. α -ethylcyclopentanone (II), b₇₈₈ 160-1°, d₄²⁰ 0.9469, d₄²⁵ 0.9260. With EtMgBr II gives 27% of 1,2-diethylcyclopentan-1-ol (III), b₄₈ 101-2°, d₄²⁰ 0.9250, d₄²⁵ 0.9041. II and PrMgBr give 8.5% of 1-propyl-2-ethylcyclopentan-1-ol, b₄₂ 115-6°, d₄²⁰ 0.9156, d₄²⁵ 0.8949. In the attempted reduction of III by satg. in the cold with HI and then refluxing with Zn, EtOH and HI, there results a 1,2-diethylcyclopentene, b₇₀₁ 148-9°, d₄²⁰ 0.9331, d₄²⁵ 0.8136.

C. J. WEST

Synthesis of certain γ -ketonic acids closely allied to Balbiano's acid. I. Synthesis of α -methylcyclopentane-1,1-diacetic acid, of the lactone of α -hydroxy- α -methylcyclopentane-1,1-diacetic acid and of 1-acetylcyclopentane-1-acetic acid. JOGENDRA CHANDRA BARDHAN. Imp. College Sci. Tech., London. *J. Chem. Soc.* 1928, 2591-604.—Previous work has shown that there is a kind of tautomerism (keto-enol type) in certain β,β -disubstituted ketoglutaric acids and that in the case of acids contg. an additional α -substituent, other factors come into play which considerably reduce the tendency to cyclopropane-ring formation. These conditions are well illustrated in the case of Balbiano's acid (*C. A.* 19, 2329; 18, 379; 16, 2141), where the usual ketocyclol change is completely suspended, the acid exhibiting a marked tendency to pass into the lactol form. It would be expected that the acid $(\text{CH}_2)_4\text{C}(\text{COCO}_2\text{H})\text{CHMeCO}_2\text{H}$ would simulate the characteristic properties of Balbiano's acid; it was assumed

that this acid could be obtained by the oxidation of the lactonic acid $(\text{CH}_3)_4\text{C} \cdot \text{CH}(\text{CO}_2\text{H}) \cdot \text{O} \cdot \text{CO} \cdot (\text{HMe})$ of the spiro compd. $(\text{CH}_3)_4\text{C} \cdot \text{CH}(\text{CO}_2\text{H}) \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CMe} \cdot \text{CO}_2\text{H}$ by alk. KMnO_4 ; these results were unsuccessful. $(\text{CH}_3)_4\text{C}(\text{CH} \cdot \text{CH} \cdot \text{CO})_2\text{NH}$

(108 g.) in 300-cc. abs. EtOH was gradually added to 35 g. Na in 500 cc. EtOH, cooled, cautiously mixed with 100 cc. MeI and allowed to come to room temp. and after 12 hrs. heated on the steam bath until neutral; distg. off the EtOH, adding 2 l. H_2O and acidifying gives 90 g. of α, α -dicyano- α -methylcyclopentane-1,1-diacetic acid *N*-methyl- ω -imide (I), m. 136-7°. Hydrolysis with H_2SO_4 or HCl gives α -methylcyclopentane-1,1-diacetic acid (II), m. 90-1°; the NH_4 salt gives a bluish green ppt. with $\text{Cu}(\text{OAc})_2$; Ag salt. Excess of Ac_2O gives the anhydride (III), b_{21} 193°, m. 48°; the β -naphthylamic acid, m. 133-4°; heating at 180° gives the β -naphthylimide, m. 179°; heating the dried NH_4 salt at 150° for 4 hrs. gives the imide, m. 123-4°. III (6 g.) and 5.3 g. Br, heated in a boiling H_2O bath for 5 hrs., give the Br anhydride, m. 95°; hydrolysis with 2 *N* Na_2CO_3 for 10 hrs. gives α -hydroxy- α -methylcyclopentane-1,1-diacetic acid lactone (IV), m. 140°; Ag salt; Ba salt; Et ester, b_{30} 197°. The di-Et ester of II, b_{31} 165°, was partially sapond. (Ag salt), treated with SOCl_2 and then with Br at 55°, giving Et α -bromo- α' -methylcyclopentane-1,1-diacetate; the hydrolysis product could not be purified; the oil, oxidized with alk. KMnO_4 and treated with $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$, gave no quinoxaline deriv. I gives an α -Br deriv., m. 180° (decompn.), which is hydrolyzed to II. Cyclopentane-1-acetic-1-carboxylic acid, m. 156-6.5°, gives an anhydride, b_{20} 154°, m. 30°; anilic acid, m. 167-7.5°; anil., m. 127-8°; mono-Me ester, m. 80-1°; acid chloride, b_{18} 132°; *p*-toluidide, m. 111°. The acid chloride and MeZnI give 1-acetylcyclopentane-1-acetic acid (V), m. 83-4°; oxime, m. 124-5°; semicarbazone, m. 197°; Me ester (VI), b_{18} 131° (semicarbazone, m. 152-3°). Reduction with Na and EtOH gives the lactone, $(\text{CH}_2)_4\text{C} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{O} \cdot \text{CHMe}$, b_{15} 132°, $d_4^{15.8}$ 1.057645, $n_D^{15.8}$ 1.4742; with KCN,

followed by acid hydrolysis, this gives II, thus establishing its constitution. Oxidation of VI with alk. KMnO_4 probably gives α -ketocyclopentane-1,1-diacetic acid, isolated as the quinoxaline, m. 221°. The action of HCN upon V gives, after hydrolysis, IV. Cyclopentanone, $\text{MeCHBrCO}_2\text{Et}$ and Mg give 50% of Et 1-hydroxy- α -methylcyclopentane-1-acetate (VII), b_{30} 130-40°; the acid showed no tendency to solidify and was therefore boiled with Ac_2O , giving α -methylcyclopentylideneacetic acid, m. 108-9°; acid chloride, b_{30} 123°; the action of MeZnI gives α -methylcyclopentylideneacetone, b_{27} 108°, $d_4^{19.2}$ 0.960808, $n_D^{19.2}$ 1.49642, which yields 2 semicarbazones, m. 189° and 169°, the latter being more sol.; both yield the same ketone. Dehydration of VII with POCl_3 in C_6H_6 gives the Et ester, b_{30} 108-10°, $d_4^{17.7}$ 0.96668, $n_D^{17.7}$ 1.4583, of α -methyl- Δ^1 -cyclopentenylacetic acid, b_{28} 150°, $d_4^{19.7}$ 1.050988, $n_D^{19.7}$ 1.4792; the acid chloride, b_{20} 86-8°, gives with MeZnI α -methyl- Δ^1 -cyclopentenylacetone, b_{17} 82°, d_4^{20} 0.921922, n_D^{20} 1.4632; semicarbazone, m. 144°. II. Syntheses of α, β, β - and α, α, β -trimethyllevulic acids, of the lactone of α' -hydroxy- α, α, β -trimethylglutaric acid and of γ -keto- α, α, β -trimethylpropane- α, γ -dicarboxylic acid (Balbiano's acid). *Ibid* 2604-21.—The keto structure for Balbiano's acid, $\text{HO}_2\text{CCOCMe}_2\text{CHMeCO}_2\text{H}$, is proved by the synthesis of the acid of this structure. The prepn. of trimethylsuccinic acid is described; the anhydride, with EtONa, gives the half ester, which gives an acid chloride with SOCl_2 ; with MeZnI this gives a mixt. of α, β, β -trimethyllevulic acid (I), m. 65-6° (semicarbazone, m. 155°; Et ester, b_{14} 110°, d_4^{19} 0.981537, n_D^{19} 1.43638), and α, α, β -trimethyllevulic acid (II), m. 77-8° (semicarbazone, m. 174°); I and II are sepd. by crystg. the semicarbazones at least 20 times from MeOH, that of II being the less sol. Oxidation of I with NaOBr gives trimethylsuccinic acid. The first attempt to synthesize II was by the reaction of $\text{EtCHBrCO}_2\text{Et}$ and $\text{AcCHMeCO}_2\text{Et}$, but this did not proceed in the expected manner. $\text{Me}_2\text{C}:\text{CMeAc}$ (semicarbazone, m. 186°) and HCN give a small quantity of an oil, from which the semicarbazone of II is obtained, but the main reaction product was the compd. $\text{Me}_2\text{C}(\text{CN})\text{CHMeCMe}(\text{OH})\text{CN}$, hydrolyzed to the compd. $\text{HN} \cdot \text{CO} \cdot \text{CMe}_2 \cdot \text{CHMe} \cdot \text{CMeCO}_2\text{H}$, m. 238° (decompn.), which resembles mesitylic

acid in its general properties. The synthesis of II was finally carried out as follows: MeEtCO and $\text{Me}_2\text{CHBrCO}_2\text{Et}$ with Zn in C_6H_6 give 55% of Et β -hydroxy- α, α, β -trimethylvalerate, b_{11} 92°; dehydration with P_2O_5 in C_6H_6 gives α, α, β -trimethyl- Δ^2 -pentenoic acid, b_{10} 113°, $d_4^{19.2}$ 0.963434, $n_D^{19.2}$ 1.45283, as the Et ester, b_{14} 100-2°, $d_4^{18.8}$ 0.906942, $n_D^{18.8}$ 1.43878; Ag salt; *p*-toluidide, m. 71°. The action of Br gives a dibromide, which loses HBr, giving a bromolactone; distn. of the latter at the ordinary

pressure gives the unsatd. lactone, $\text{Me}_2\text{C}(\text{Me}:\text{CMe}:\text{O}:\text{CO})$; b_p 10°; with 20% MeOH-

KOH this gives II; the *p*-nitrophenylhydrazone of II, yellow, m. 207°; the piperonylidene deriv. lemon-yellow, m. 115°. Oxidat. of I with alk. KMnO_4 gives Balbiano's acid, m. 119°; the synthesis of this acid is consistent only with the keto formula and the solid acid probably exists in this form. $\text{AcCMe}_2\text{CO}_2\text{Et}$ and $\text{ClCH}_2\text{CO}_2\text{Et}$ with EtONa give the oxidic ester, $\text{EtO}_2\text{CCMe}_2\text{CMeCHCO}_2\text{Et}$; b_p 162°; hydrolysis gives an

extremely viscous oil, which did not give a semicarbazone. $\text{OHCCHMeCMe}_2\text{CO}_2\text{H}$ and HCN give a cyanolactone, which is hydrolyzed to the α' -hydroxy- α,α,β -trimethylglutaric acid lactone, m. 110°; oxidation with alk. KMnO_4 gives trimethylsuccinic acid. Oxidation of β,β -dimethyllevulic acid gives α,α -dihydroxy- β,β -dimethylglutaric acid, m. 82-3°.

C. J. WEST

Base formation from carbonyl compounds. II. A. SKITA AND F. KEIL, IN PART WITH E. BAESLER AND L. BOENTE. Techn. Hochschule Hannover. *Ber.* 61B, 1682-92 (1928); cf. *C. A.* 22, 4502.—Anilines can also react like aliphatic bases with ketones to form secondary amines; cyclohexanone (I) and PhNH_2 on catalytic reduction with colloidal Pt give *N*-phenylcyclohexylamine (II) in excellent yield. II. HCl , m. 204-5°, is stable in the air and not easily sol. in H_2O , while according to Sabatier and Senderens (*Compt. rend.* 138, 459(1904)) the base obtained by them by the hydrogenation of PhNH_2 and Ph_2NH forms an easily sol. HCl salt unstable in the air. Moreover as the color reactions described by them for their base on oxidation differ entirely from those of II it is not at all certain that they had II. Me_2CO and Et_2CO react like MeCOEt and I with primary amines to form secondary bases, indicating that ketones quite generally react with aliphatic amines and anilines, even in H_2O suspension, to form intermediate *N*-substituted imines, which are then reduced to secondary amines: $\text{RR}'\text{CO} + \text{R}''\text{NH}_2 \rightarrow \text{RR}'\text{C}:\text{NR}''(+\text{H}_2) \rightarrow \text{RR}'\text{CHNHR}''$. On the other hand control expts. have fully confirmed Mignonac's claim (*Fr. pat.* 529,139, July 3, 1920) that I and NH_4OH reduced under the most varied conditions with Ni give the primary cyclohexylamine (III) exclusively; Me_2CO , MeCOEt and Et_2CO behave in the same way, and as aldehydes likewise give chiefly primary amines, the reaction of $\text{C}:\text{O}$ compds. on reduction with Ni may be quite generally represented by the scheme $\text{RCHO} + \text{NH}_3 \rightarrow \text{RCH}:\text{NH}(+\text{H}_2) \rightarrow \text{RCH}_2\text{NH}_2$, while the formation of secondary amines with colloidal Pt can take place only through the further reaction $\text{RCH}_2\text{NH}_2 + \text{RCHO} \rightarrow \text{RCH}_2\text{N}:\text{CHR}(+\text{H}_2) \rightarrow \text{RCH}_2\text{NHCH}_2\text{R}$. By progressively decreasing the quantity of catalyst in the reduction of I with Pt, increasingly large quantities of II (although never as large as those of dicyclohexylamine (IV)) are formed if the reduction is carried out at the same temp. (90°) as with Ni, but at room temp. even the smallest quantities of Pt give IV exclusively. At 90°, therefore, the intermediate compd. $\text{RCH}_2\text{N}:\text{CHR}$ is present in smaller concn. than at room temp. but since the stronger Pt catalyst can still reduce it to IV even when it is present in this smaller concn., the temp. cannot be the only factor in the difference between Pt and Ni; the Ni must have no power (or a markedly lesser power than Pt) to reduce the $\text{RCH}_2\text{N}:\text{CHR}$ so that the reduction practically stops at the 1st stage (RCH_2NH_2). In agreement with this is the fact that equimol. quantities of Me_2CO , MeCOEt , Et_2CO or I on the one hand and III on the other hand form no secondary amine with Ni, while with Pt more than 50% of the secondary amine is formed both at room temp. and at 90°. BzH and MeCOPh can likewise be converted into the secondary amines in NH_4OH suspension with Pt. That Knoop and Oesterlin with Pd sponge obtained secondary amines only with BzH and $\text{PhCH}_2\text{CHCHO}$ and not with Ph_2CO shows that Pd sponge is a weaker catalyst than Pt and stands between Pt and Ni. The formation of tertiary amines probably proceeds according to the scheme $\text{RCH}_2\text{NHCH}_2\text{R} + \text{RCHO} \rightarrow (\text{RCH}_2)_2\text{N}:\text{CH}(\text{OH})\text{R}(+\text{H}_2) \rightarrow (\text{RCH}_2)_3\text{N}$; AcH and PhCH_2NHEt with colloidal Pt in both acid and alk. soln. gave $\text{PhCH}_2\text{NEt}_3$ (V). NH_3 alcs. can be prepd. in this way from dicarbonyl and hydroxycarbonyl compds. Thus CH_3Ac_2 and III gave 2-cyclohexylamino-4-pentanol (VI) through the intermediate compd. $\text{MeC}(\text{NC}_6\text{H}_{11})\text{CH}_2\text{Ac}$, HOCH_2Ac yielded 2-cyclohexylaminopropanol (VII) and from arabinose and mannose were obtained *N*-cyclohexylarabinamine (VIII) and -mannamine (IX), resp. II, b_p 146-8°, gives no blue and purple color with CrO_3 and HNO_3 , resp. but with HIO_3 instantly gives a deep violet color. *N*-Isopropylcyclohexylamine (79% from Me_2CO , III and colloidal Pt with H_2 under 3 atm. overpressure at room temp.), b_p 169-71°; HCl salt, m. 204-5°; picrate, m. 142°. *N*-sec-Butylcyclohexylamine (yield, 60%), b_p 193°; HCl salt, m. 211°; picrate, m. 118°. *N*- α -Ethylpropylcyclohexylamine (31%), b_p 208-9°; HCl salt, m. 178°; picrate, m. 124°. BzH and alc. NH_3 with colloidal Pt gave $(\text{PhCH}_2)_3\text{N}$.

NH; 20 g. MeCOPh gave 3 g. each of (Me₂CHPh)₂NH, b. 145-8°, and MeCHPhNH₂, b. 185-90°; from Et₂CO were obtained Et₂CHNH₂ (HCl salt, m. 216°), and bis- α -ethylpropylamine, b. 172-4°; HCl salt, m. 115-7°. Me₂CO (15 g.) with NH₄OH and a Ni catalyst at 90° under 20 atm. gave Me₂CHNH₂ (8 g. of the deliquescent HCl salt, m. 148-50°); MeCOEt (17 g.) yielded 5 g. EtMeCHNH₂, b. 62-3° (HCl salt, m. 144-5°); Et₂CO gave Et₂CHNH₂, b. 90-4°. AcH (22 g.) and aq. EtNH₂ with colloidal Pt gave about 4 g. each of NHEt₂ and NEt₃. V was obtained in 9 g. yield from BzH, AcH and NH₂Et with colloidal Pt and in over 50% yield from PhCH₂NHEt and AcH (in acid soln. the yield was reduced to 15%). VI (10 g. from 20 g. CH₃Ac), b. 123-5°; HCl salt, m. 157-8°; di-Ac deriv., b. 183° (in H₂). VII, b. 116-7°, begins to cryst. after some days; HCl salt, m. 148-9°. VIII, m. 135-7°; HCl salt, m. 167°. IX, HCl, m. 165-7°.

C. A. R.

Chaulmoogric oils. The oil of Gorli. EMILÉ ANDRÉ AND DANIEL JOUATTE. Hospice de la Salpêtrière, Paris. *Bull. soc. chim.* 43, 347-60(1928); cf. C. A. 20, 1130.—Oils from seeds of the *Flacourtiaceae* have long been used by tropical peoples for the treatment of skin diseases, including leprosy. These oils are strongly d-rotatory because of the presence of glycerides of acids of the cyclopentene series, chaulmoogric (I) and hydnocarpic acids having been identified; they have not been found in the oil from any other family. *Oncoba echinata*, Oliver, called Gorli or Katoupo, is important because it is the only member of the *Flacourtiaceae* in Africa, where there is much leprosy, and the oil of Gorli contains 87.5% of I. A pure product can be obtained because there are no other chaulmoogric seeds in Africa to become mixed with Gorli seeds. The seeds yield 39-52% of oil of Gorli upon extn. with ether; the solidified oil m. 40-2°, d₂₀²⁵ 0.9286, n_D²⁰ 1.4740, α 56° 10', sapon. no. 184.5, I no. (Hanus) 98. *Trichaulmoogrin*, whose presence in oil of Gorli is certain, could not be sepd. by crystn. with Me₂CO and petroleum ether, but 3 glyceride fractions were obtained, (a) (40%) m. 51°, (b) (40%) pasty, and (c) (20%) oil. (a), sapon. no. 194, I no. 72.5, α 49° 20'; (c), sapon. no. 194, I no. 108, α 46° 25', d₂₀²⁵ 0.9482, n 1.4828. From (a), (b) and (c) the fatty acids were obtained and sepd. by fractional crystn., fractional distn. of the Et esters at reduced pressure, or fractional pptn. of the acids in alc. by Mg(OAc)₂ or Ba(OAc)₂ (method of Heintz). (a) contained 85% of I and 15% of palmitic acid (II); (b), 80% of I, about 10% of II, and about 10% of gorlic acid (III); (c), 70% of I, 10% of II, and 20% of III. *Trichaulmoogrin* (IV), prepd. by the method of Scheij (1899), m. 45°; it is noteworthy that this m. p. is lower than that of I, whereas usually the glycerides of solid, straight-chain fatty acids melt higher than do the acids. The presence of II in oil of Gorli was established for the first time. III was definitely characterized, although it was not obtained in a rigorously pure state; it is C₁₅H₂₆O₂, of the same family as I and hydnocarpic acid, with one more double bond. Its I no. (170) is low because of the presence of I and because the nature of its double bonds does not permit adding the theoretical quantity of I. Perhaps one double bond is in the 5-atom ring and the other in the side chain. Li salt of III m. 163° (decompn.) on the Maquenne block. Gorlic amide m. 95°. Dean and Wrenshall (C. A. 19, 2476) obtained from com. chaulmoogra oil an acid which may be identical with III. To prep. I from oil of Gorli, 100 g. of oil was refluxed 0.5 hr. with 100 g. 90% alc. and 50 g. NaOH. H₂O and excess HCl were added and I was extd. with Et₂O. The ext. was washed with H₂O and dried, and the Et₂O removed. I (95 g.) solidified upon cooling, was recrystd. from 95% alc. several times, then converted into Et chaulmoograte (V) with an equal wt. of 96% EtOH and concd. H₂SO₄ (0.01 wt.); V b. 218-20°; it was sapond. and the resulting I was recrystd. I m. 68°, sapon. no. 198.6, I no. 90.7, α 61.504°. I b. 235° and can be purified by distn., but A. and J. prefer to distil it in the form of V. IV was prepd. from pure C₃H₅(OH)₂ and a slight excess of pure I at 100° under 20-25 mm., CO₂ being introduced meanwhile; the heating was continued for 8 days, 6-7 hrs. per day. Excess I was removed with hot EtOH and IV was recrystd. from Me₂CO. IV m. 45°, n_D²⁰ 1.4764, d₂₀²⁵ 0.9437, α 54° 50', sapon. no. 190.6, I no. 87.3. The presence of a solid, straight-chain fatty acid in oil of Gorli is indicated by the fact that, from the alc. mother liquors obtained in the purification of I were obtained by concn., products whose sp. rotations, m. ps. and I nos. became progressively lower. II was obtained as follows: the acids from the mother liquors of I were esterified with EtOH and H₂SO₄, the esters being distd. under reduced pressure in a current of CO₂. A low-boiling portion was redistd., and certain low-boiling fractions thus resulting were sapond. and the acid recrystd. from EtOH. II is not assocd. with any homologous fatty acid in oil of Gorli. III is prepd. from (c), the liquid glycerides of oil of Gorli, as follows: (c) is sapond. with an equal wt. of 95% EtOH and 0.5 the wt. of pure 36% NaOH. HCl

is added, the acids are extd. with H_2O , the ext. is washed with H_2O , and dried and the Et_2O removed by evapn. The acids are treated with 90% EtOH to sep. the liquid acids from most of the solid acids present, the mother liquors being concd. and then filtered. The liquid acids are esterified with EtOH and H_2SO_4 , and the esters in Et_2O are washed with salt H_2O , and then with H_2O ; the Et_2O is removed by evapn. The residue is distd. under reduced pressure in CO_2 . Fractions rich in Et gorlate, as detd. by the I no., are redistd. The product is sapond., and the acids sepd. The solid acids, contaminated with oil, had an I no. of 120–30; recrystn. from EtOH gave I and II, with III in the mother liquor. The liquid acids, mostly III, had an I no. of 150–70, the theoretical for $\text{C}_{18}\text{H}_{30}\text{O}_2$ with 2 double bonds being 181. Further purification was abandoned for lack of material. III is a colorless liquid becoming slightly yellow upon contact with air, d^{20}_4 0.9364, n 1.4783, α 50° $18'$, sapon. no. 199.5, I no. (Hanus) 169.6. Li gorlate was prepd. as follows: III was refluxed 2 hrs. with 70% EtOH and 2 times the theoretical quantity of Li_2CO_3 . The excess Li_2CO_3 was removed by filtration, the alc. soln. was concd. by distn. and left in *vacuo* over H_2SO_4 . It solidified but could not be purified. Other gorlates gave less satisfactory results. The amide (VI) of III was prepd. as follows: 60 g. SOCl_2 (VII) and 20 g. III were refluxed 2 hrs. on the water bath. The excess of VII was removed by cautious distn. and the residue was dropped into satd. aq. NH_3 at -15° . VI was washed with H_2O , dried and crystd. several times from Me_2CO ; VI m. 95° .

MARGARET W. MCPHERSON

Isomerization of dicyclohexylacetaldehyde to a ketone. E. VENUS-DANILOVA. Staats-Univ. Leningrad. *Ber.* 61B, 1954–66(1928).—The study of the isomerization of aldehydes into ketones (C. A. 21, 2465, and earlier papers) has been extended to dicyclohexylacetaldehyde (I). Dicyclohexyl(ethoxymethyl)carbinol (α , α -dicyclohexylethyleneglycol β -Et ether) is obtained in 136.5 g. yield, together with Et cyclohexylacetate, cyclohexyl(ethoxymethyl)carbinol (the still impure product (C 69.83–70.19, H 11.85–11.90, EtO 25.27%, mol. wt. in freezing C_6H_{12} 166.1) b_{25} 108°), and dicyclohexyl, from 385 g. cyclohexyl bromide, 55.2 g. Mg and 152 g. $\text{EtOCH}_2\text{CO}_2\text{Et}$; it b_{18} 181° , m. 53° , mol. wt. in freezing C_6H_{12} 257.5–272.5. With crystd. $(\text{CO}_2\text{H})_2$ in CO_2 at $112-8^\circ$ it gives 75% I, b_{11} $153-3.5^\circ$, mol. wt. in freezing C_6H_{12} 191.6–7.5, d^{20}_4 0.9808, d^{20}_{20} 0.9676, d^{20}_4 0.9621, reacts only faintly with fuchsin- SO_2 , NH_3 - Ag_2O and NaHSO_3 ; semicarbazone, m. $184-4.5^\circ$; oxime, m. $108-9^\circ$. With freshly pptd. Ag_2O in alc. at 100° I yields 48.8% of the acid, m. $134-5^\circ$, mol. wt. in freezing C_6H_{12} 214.3–222.1, also obtained from I allowed to stand in the air or, most conveniently, by passing O through I in 96% alc. (77.4% yield); Ca salt, scales with 1 H_2O ; Ag salt, decomps. on evapn. of its solns. Anilide, through the chloride (prepd. with SOCl_2), m. 203° . Amide, m. $188-9^\circ$. From 86 g. cyclohexylcarbinol iodohydrin, 8.5 g. Mg and 35 g. hexahydrobenzaldehyde are obtained cyclohexylcarbinol, b_{14} 83° , 8.1 g. α , β -dicyclohexylethane, b_{11} 136° , mol. wt. in freezing C_6H_{12} 192.2, and 20.6 g. 1,2-dicyclohexylethanol (α , β -dicyclohexylethyl alc.) (II), b_{14} $162-4^\circ$, m. $64-5^\circ$, mol. wt. in freezing C_6H_{12} 213.7. With $\text{K}_2\text{Cr}_2\text{O}_7$ - H_2SO_4 II gives 65–75% of the 1-ethanone (dodecahydrodesoxybenzoin) (III), b_{16} $164-5^\circ$, b_{28} 172.3° , mol. wt. in freezing C_6H_{12} 194.3–198, d^{20}_4 0.9666, d^{20}_{20} 0.9527, d^{20}_4 0.9511; semicarbazone, m. $190-1^\circ$; oxime, m. $112-3^\circ$. Alc. KOH at $145-8^\circ$ decomps. III into cyclohexane and cyclohexylacetic acid. Unlike desoxybenzoin, III cannot be methylated with NaOEt and MeI . When I is treated with cold concd., or hot dil. H_2SO_4 , or with alc. HgCl_2 , it gives III, which is also formed from the semicarbazone of I with hot, moderately concd. H_2SO_4 . C. A. R.

Degradation studies of unsaturated acids of high molecular weight. The degradation of chaulmoogric acid to homohydnocarpylamine. A modified Curtius degradation. C. NÄGELI AND G. STEFANOVITSCH. *Helv. Chim. Acta* 11, 609–56(1928).—A critical review of the many methods which may be employed for the degradation of acids is given and it is pointed out that the method of Lossen (cf. *Ann.* 161, 357(1872)) is not given in the standard reference handbooks; this method (cf. C. A. 21, 3900) is based on the reactions of hydroxamic acids as follows:

Attempts were made to degrade chaulmoogric acid (I) by means of Hoffman's method as employed by Weerman and Rinkes (cf. C. A. 3, 64; 21, 2874), but with little success since it was not certain that a pure urethan was isolated from the reaction mixt.

This part of the work will be repeated the starting material is available. The starting material was a com. sample of "Ol. *Gynocardiae*" (cf. Power and Barrow-cliff, *J. Chem. Soc.* 87, 896(1905); *C. A.* 18, 1155), d_4^{20} 0.9521, $m.$ 29–31°, $[\alpha]_D^{17}$ 55.16 (CHCl_3), n_D^{20} 1.4779, acid no. 14.76, sapon. no. 197.2, I no. 98.11, $m.$ p. of fatty acids 42°. The sapon. of 2 kg. of the oil was done in a H_2 atm. by the method of Grün and Schönfeld (cf. *C. A.* 10, 2210) and gave 1900 g. fatty acids having a yellow color when solid, deep red when melted and free from unsaponifiable matter. The moisture-free acids (500 g.) were fractionated at 0.5 mm. from a Claisen flask in a H_2 atm. and gave (a) 180 cc. $m.$ 43–6°, (b) 140 cc. $m.$ 40–1°, (c) 180 cc. $m.$ 46–52°, residue, 50–75 g. (cf. *C. A.* 19, 2980); a and b (640 g.) were united, dissolved in 2 l. of hot 96% EtOH, allowed to stand undisturbed until about 150 g. of acids had sepd. at room temp., and filtered; the operation was repeated with the filtrate until no more acids sepd. (total about 350 g., $m.$ 59–66°); the sepd. acids were redissolved in hot 96% EtOH and the fractional sepn. was repeated, giving pure I (152 g.). The degradation of I to homohydnocarpylamine (II) was accomplished by the method of Curtius; the yields of some of the products were quite low. Chaulmoogryl chloride (III), $\text{C}_4\text{H}_5\text{CH}(\text{CH}_2)_{12}\text{COCl}$, was prepd. by heating equal parts of I and SOCl_2 for 1.5 hrs. at 55°, removing excess SOCl_2 with a stream of dry air in *vacuo* at 60°, treating 3–5 times with CCl_4 and removing the latter each time in *vacuo* at 60°; distn. at 2 mm. gave decompn.; prepn. with I and PCl_3 or PCl_5 gave an impure product. *N,N'*-Dichaulmoogryl hydrazide (IV), $[\text{C}_4\text{H}_5\text{CH}(\text{CH}_2)_{12}\text{CONH}]_2$, was obtained in 86% yield by adding slowly 5 g. III to 2.5 g. $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$, warming, washing the ppt. with H_2O and 70% EtOH-Et₂O and recrystg. from EtOH; in a similar manner, 2.5 g. III added to 2.5 g. $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ in 50 cc. cold H_2O gave a 94.8% yield; an emulsion of 5 g. $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ in 120 cc. PhH added to 10 g. III in cold PhH gave a 77.4% yield. When III (20 g.) in 150 cc. abs. Et₂O was added during 3 hrs. with stirring to 10 g. $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ in 300 cc. EtOH at –2°, stirred and kept cold for 2 hrs. more, the EtOH and Et₂O removed in *vacuo*, the residue washed with H_2O , dried, washed with Et₂O and recrystd. from EtOH, it gave 7.8 g. IV and 9.5 g. chaulmoogryl hydrazide (V), $\text{C}_4\text{H}_5\text{CH}(\text{CH}_2)_{12}\text{CONHNH}_2$, which is more sol. than IV and is converted to IV when treated with III in PhH. In a similar manner BzNHNH_2 can be obtained almost quant. from BzCl in Et₂O and $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ in EtOH. A 79% yield of V was obtained when 50 g. Et chaulmoograte (cf. Power and Gornall, *J. Chem. Soc.* 85, 855(1904)) was added slowly during 3 hrs. to 32 g. $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ at 100°, heated 2 hrs. longer at 100° (the EtOH formed in the reaction escapes through a reflux condenser kept hot with steam), then 30 min. at 120°, cooled, the 18 g. of solid residue treated with EtOH and Et₂O to remove the unchanged starting products, which were recovered from soln. and heated 18 hrs. at 140°, giving 26 g. more; the product thus obtained contains an impurity of unknown constitution (VI), $m.$ 132–3°, from which V was sepd. by dissolving in 500 cc. dry CHCl_3 , cooling to 6°, passing dry HCl into the CHCl_3 soln. during 1 hr., filtering and washing the HCl salt of V with cold CHCl_3 and then converting to the base with the calcd. quantity of alc. KOH; V forms colorless crystals, $m.$ 92°, $[\alpha]_D^{22}$ 28.34° (CHCl_3); the HCl salt, $m.$ 115–20°, decomp. 130°; BzCl and V in hot PhH gave *N*-benzoyl-*N'*-chaulmoogryl hydrazide, $\text{C}_4\text{H}_5\text{CH}(\text{CH}_2)_{12}\text{CONHNHBz}$, which was recrystd. from EtOH and $m.$ 114°; benzalchaulmoogryl hydrazide, $\text{C}_4\text{H}_5\text{CH}(\text{CH}_2)_{12}\text{CONHN}:\text{CHPh}$, from BzH and V in EtOH, $m.$ 89.5–91°; *o*-hydroxybenzalchaulmoogryl hydrazide, from $\text{C}_6\text{H}_4(\text{OH})\text{CHO}$ and V, $m.$ 109°. When V was heated to 160° for 5 hrs. it gave quant. VI, C 77.89%, H 12.24%, N 9.11%, mol. wt. 585, $[\alpha]_D^{22}$ 21.54°; no definite conclusion was reached as to the nature of this compd. but it is suggested that it might be 3,5-dihomohydnocarpyl-4-amino-1,2,4-triazole, $\text{C}_{17}\text{H}_{31}\text{C}:\text{N}:\text{N}:\text{C}(\text{C}_{17}\text{H}_{31})\cdot\text{NNH}_2$ (cf. *C. A.* 8, 3042). Chaulmoogryl azide (VII),

$\text{C}_4\text{H}_5\text{CH}(\text{CH}_2)_{12}\text{CON}_3$, was prepd. by slowly adding 5–6 cc. concd. HCl to a cold mixt. of 12.2 g. V in 200 cc. 90% EtOH and 2.6 g. NaNO_2 in a little H_2O , pptg. with 800 cc. ice water, filtering after 0.5 hr., washing with cold H_2O , 0.2% Na_2CO_3 , then H_2O , dissolving in Et₂O and drying over Na_2SO_4 or CaCl_2 ; it is unstable, gradually decompg. with evolution of N_2 , but does not explode on heating or by percussion; VII in dry Et₂O on boiling with abs. EtOH for 1 hr. gave 50% of Et homohydnocarpylcarbamate (VIII), $\text{C}_4\text{H}_5\text{CH}(\text{CH}_2)_{12}\text{CH}_2\text{NHCO}_2\text{Et}$, $m.$ 48.5°, $[\alpha]_D^{22}$ 47.62° (CHCl_3); 50% of sym-homohydnocarpylurea (IX), $[\text{C}_4\text{H}_5\text{CH}(\text{CH}_2)_{12}\text{CH}_2\text{NH}]_2\text{CO}$, $m.$ 113.5°, was obtained when VII in Et₂O was added slowly to a large vol. of boiling H_2O . A 26% yield of II $\text{C}_4\text{H}_5\text{CH}(\text{CH}_2)_{12}\text{CH}_2\text{NH}_2$, was obtained by heating 2 g. VIII and 20 g. 35% HCl in a sealed tube for 8 hrs. at 100°, adding KOH until alk., extg. with Et₂O, drying with KOH and distg. off the Et₂O; 40% was obtained when 10 parts IX and 40 parts $\text{Ca}(\text{OH})_2$ (from

70 parts CaO and 30 of H₂O) were mixed and distd. into HCl, treated with KOH and extd. with Et₂O; it forms a light yellow liquid with a disagreeable odor, decomp. on distn. *in vacuo* and changing in air to the carbamate; the HCl salt, m. 160°; the aq. soln. decomp. on evapn., $[\alpha]_D^{25}$ 54.90° (abs. EtOH); the picrate, m. 112°; the chloroplatinate is slightly sol. in 96% EtOH and insol. in Et₂O or H₂O. When 10 g. NaN₃ (X) (cf. C. A. 2, 3315) was added to 32 g. III in 150 cc. abs. Et₂O, boiled 3 hrs., then 170 cc. abs. EtOH added, the Et₂O removed by distn., boiled 1 hr., 70 cc. EtOH removed by distn., cooled, 500 cc. ice H₂O added, the ppt. filtered, washed with H₂O, recrystd. from 96% EtOH with charcoal, 89–91% VIII and 10–9% IX were obtained; similarly when aq. Et₂O was used the yields were 84–7% and 15–13%, resp.; VIII and IX were sepd. by fractional crystn. from EtOH in which VIII is very sol. and IX is very slightly sol.; IX was also prepd. in 96% yield when 5 g. III in 50 cc. Et₂O and 5 g. X were boiled for 3 hrs. and then treated with H₂O. The yields of the products obtained by inter-action with X depend upon some unknown quality of X and in some cases only traces of VIII and IX were obtained.

N. A. LANGE

Molecular transposition in the cycloheptane series. MARCEL GODCHOT AND GERMAINE CAUQUIL. *Compt. rend.* 186, 955–7 (1928); cf. C. A. 22, 8.—PhMgBr and 2-chlorocycloheptanol yield phenylcyclohexylcarbinol, m. 48–9° (whose phthalate m. 163°, phenylurethan m. 146°), and an ethylenic hydrocarbon, C₁₃H₁₆, b₁₅ 140–1°. The formation, by this reaction, of a ring contg. 1 less C atom thus appears to be the general tendency. The mechanism suggested by Tiffeneau:

A. L. HENNE

Alternating reactive positions in the nucleus of *tert*-butylbenzene. JOHN B. SHOESMITH AND ALEXANDER MACKIE. *Edinburgh Univ. J. Chem. Soc.* 1928, 2334–40.—When a substituent enters the nucleus of PhCMe₃ it does so almost exclusively in the *p*-position; the isolation of the *o*-NO₂ deriv. reported by Senkowski (*Ber.* 23, 2414 (1890)) has been confirmed and a further example of the alternating influence of the CMe₃ group has been found in that, when treated with HI, the isomeric IC₆H₄-CMe₃ only react if the I is in the *o*- or *p*-position. Nitration of PhCMe₃ with HNO₃ of d. 1.52 gave only the *p*-NO₂ deriv., b₁₀ 125–30°; nitration with a mixt. of HNO₃ and H₂SO₄ gives the 2,4-di-NO₂ deriv., m. 61–2°, reduced by NH₄OH and H₂S to 2-nitro-4-amino-*tert*-butylbenzene, yellow, m. 55° (*Ac deriv.*, m. 112°); removal of the NH₂ group gives the *o*-O₂NC₆H₄CMe₃, yellow oil, b₁₀ 114–5°, b₇₆₅ 250.5°; the *o*-NH₂ deriv., b₁₀ 102°; Me₃CC₆H₄N₂HSO₄ is very unstable and appears to decomp. at about –8°; KI gives *o*-iodo-*tert*-butylbenzene, b₁₀ 116–8°; the *m*-I deriv., b₁₀ 106–8°. Heating *p*-O₂NC₆H₄CMe₃, Br and Fe at 90° gives the 2-Br deriv., m. 94.5°; reduction with Fe and concd. HCl gives 2-bromo-4-amino-*tert*-butylbenzene, pale yellow, b₁₁ 153–5° (*HCl salt*, m. 235° (decompn.); *Ac deriv.*, m. 142–3°); elimination of the NH₂ group gives *o*-bromo-*tert*-butylbenzene, b₁₂ 96–8°. The *o*-I or Br deriv. with Mg and then with CO₂ gives *o*-*tert*-butylbenzoic acid, m. 68.5°. The following figures give the % of the *o*- and *p*-IC₆H₄CMe₃ reduced by HI in AcOH at 25°: 2 days, 61, 11; 4 days, 76, 19; 14 days, 86, 35; the *m*-isomer is unchanged. The order of reduction was unchanged even at 100° and 110°.

C. J. WEST

***p*-Cymene studies. XI. *p*-Cymyl-2-carbithioic acid.** ALVIN S. WHEELER AND CHARLES L. THOMAS. *Univ. of North Carolina. J. Am. Chem. Soc.* 50, 3106–9 (1928); cf. C. A. 22, 3147–8.—The Grignard reagent from 2-bromo-*p*-cymene and CS₂ at –10° give *p*-cymyl-2-carbithioic acid, MePrC₆H₄CS₂H, a viscid, red oil, which does not solidify at –15° and when heated at 2 mm. decomp. long before there is any evidence of boiling; the Et₂O solns. range from purple-red (concd.) to orange (dil.); the acid is fairly stable in this soln.; the Zn salt, yellow-ccher, amorphous powder, m. 92°; the Me ester, b₈ 167–8°; Et ester, b₈ 141–2°. Addn. of a metallic salt in dil. AcOH soln. to the Na salt of the above acid in H₂O gives complex salts of the type MePrC₆H₄CS₂-M-OAc: Zn, yellow, m. 196° (decompn.); Cu, red-yellow, m. 75° (decompn.); Hg, yellow, m. above 300°; Cd, m. 125° (decompn.); all are amorphous; the Pb salt is brown, m. 65°; the Ag salt is orange but turns black in 15 min. The acid and Ph-NHNH₂ give a compd., m. 112°, contg. 6.79% N and 16.18% S. PCl₅ gives a compd. b₈ 141°, which gives no typical reaction with NH₃ or PhNH₂.

C. J. WEST

The action of nitric acid on derivatives of ethylene. II. Nitration of some styrene derivatives. J. VAN DER LEE. *Cell. of Tropical Agr., Deventer, (Holland). Rec. trav. chim.* 47, 920–33 (1928); cf. C. A. 21, 399.—Previously the action of abs. HNO₃

on Et nitrocinnamates and nitrocinnamic acid has been investigated and it was shown that the HNO_3 adds to the ethylenic linkage, Et α -nitro- β -hydroxynitrate- β -nitrophenylpropionates being formed from the esters, and ω -dinitrostyrenes from the acids, in the latter case CO_2 being split off from the primary product of the reaction. The present communication deals with the action of abs. HNO_3 on 4,4'- and 3,3'-dinitrodibenzalacetone, 3- and 4-nitrobenzalacetone, 3,3'- and 4,3'-dinitrochalcone, 4,4'-Dinitrodibenzalacetone, prepd. from $p\text{-O}_2\text{NC}_6\text{H}_4\text{CHO}$ and acetone (J. prakt. Chem. [2] 60, 154(1899)) and from $\text{HO}(4\text{-O}_2\text{NC}_6\text{H}_4)\text{CHCH}_2\text{COMe}$ by adding strong potash to the boiling solution of 2 g. of the ketone in 400 cc. boiling water, m. 247° . In the latter case the ketone is partly split into acetone and $p\text{-O}_2\text{NC}_6\text{H}_4\text{CHO}$, which acts upon the starting product with the formation of $(p\text{-O}_2\text{NC}_6\text{H}_4\text{CH:CH})_2\text{CO}$. With abs. HNO_3 this compd. is converted into ω ,4-dinitrostyrene, m. $200\text{--}2^\circ$, CO_2 being evolved. 3,3'-Dinitrodibenzalacetone, m. 237° , was obtained by both the methods described above for the 4,4'-compd., HNO_3 giving ω ,3-dinitrostyrene, m. $122\text{--}3^\circ$. 4-Nitrobenzalacetone (Ber. 16, 1968(1883)) also was converted by means of HNO_3 into ω ,4-dinitrostyrene, and 3-nitrobenzalacetone (Ann. 294, 293(1897)) into ω ,3-dinitrostyrene. 3,3'-Dinitrochalcone was prepd. from $3\text{-O}_2\text{NC}_6\text{H}_4\text{COMe}$ and $m\text{-O}_2\text{NC}_6\text{H}_4\text{CHO}$ in alc. with a small quantity of alkali; with abs. HNO_3 alone or mixed with AcOH or Ac_2O , α ,3,3'-trinitrochalcone (I), $\text{O}_2\text{NC}_6\text{H}_4\text{CH:C}(\text{NO})_2\text{COC}_6\text{H}_4\text{NO}_2$, m. $152.5\text{--}4^\circ$, was obtained. The structure of the reaction product was proved by the action of KOH in MeOH , the soln. thus obtained being treated afterwards with Br water, 1,1'-dibromo-3,1'-dinitro-1'-methoxy-1-ethylbenzene (II), $3\text{-O}_2\text{NC}_6\text{H}_4\text{CH}(\text{OMe})\text{C}(\text{NO}_2)\text{Br}_2$, m. 154° (cf. Ann. 229, 237(1885)) being obtained. On recrystg. I from MeOH or EtOH the alc. adds to the double bond with the formation of β -nitro- γ -methoxy- α -keto- α , γ -di-[3-nitrophenyl]propane (III), m. 128.5° , and the γ -EtO homolog, (IV), m. $120.5\text{--}1^\circ$. The structure of III and IV was proved by the formation of II and V, m. 97° (Ann. 229, 237(1885)) by the action of alkali and Br water. From $4\text{-O}_2\text{NC}_6\text{H}_4\text{CHO}$ and $3\text{-O}_2\text{NC}_6\text{H}_4\text{COMe}$ 4,3'-dinitrochalcone, m. 205.5° , was obtained by the action of dil. alkali on the alc. soln. of the components. With abs. HNO_3 this compd. is converted into α ,4,3'-trinitrochalcone (VI), m. 135° . On recrystn. from MeOH VI was converted into β -nitro- γ -methoxy- α -keto- α -[3-nitrophenyl]- γ -[4-nitrophenyl]propane (VII), m. 122.5° , which with alkali and Br was converted into 1,1'-dibromo-4,1'-dinitro-1'-methoxy-1-ethylbenzene (VIII), m. $159\text{--}60^\circ$ (cf. Ann. 325, 16(1902)), thus proving the constitution of VI.

C. F. VAN DUIN

Intermolecular condensation of styryl ketones. II. Styryl nonyl ketone and the formation of dimerides. ISIDOR M. HEILBRON and FRANCIS IRVING. Univ. of Liverpool. J. Chem. Soc. 1928, 2323-6; cf. C. A. 21, 3611.—Bis[styryl nonyl ketone] (Carette, Compt. rend. 131, 1225(1900)) yields a monoxime, m. $125\text{--}6^\circ$. $p\text{-MeOC}_6\text{H}_4\text{CHO}$ (3.2 g.) and 4 g. Me nonyl ketone(I), refluxed 6 hrs. with 30 cc. 1% EtOH-KOH , give bis-[4-methoxystyryl nonyl ketone], m. 120° . Veratraldehyde (4 g.) and 4 g. I in 10 cc. EtOH and 2 cc. 8% NaOH give, after 12 hrs., 5.5 g. 3,4-dimethoxystyryl nonyl ketone, pale yellow, m. 61° ; if the 2 components are refluxed with 25 g. 1% EtOH-KOH , there results bis-[3,4-dimethoxystyryl nonyl ketone], m. 135° . Piperonal and I with EtOH-KOH give bis-[3,4-methylenedioxy-styryl nonyl ketone], m. 128° . $p\text{-MeC}_6\text{H}_4\text{CHO}$ and I and bis-[4-methylstyryl nonyl ketone], m. $134\text{--}5^\circ$; Scholtz and Meyer (C. A. 4, 2806) describe this compd. as 4-methylstyryl nonyl ketone, m. 129° . Cumin-aldehyde and I in EtOH and NaOH give 4-isopropylstyryl nonyl ketone (II), m. 40° ; the use of 15% NaOH gives the dimeride, m. 150° , described by S. and M. as II, m. 144° . $p\text{-ClC}_6\text{H}_4\text{CHO}$ and I with 8% NaOH give 4-chlorostyryl nonyl ketone, m. $62\text{--}3^\circ$; refluxing with 1% EtOH-KOH gives the dimeride, m. $126\text{--}7^\circ$. The 3-Cl deriv., m. 57° ; the 2-Cl deriv. could not be crystd. and was identified as the semicarbazone, m. $123\text{--}4^\circ$. 2-Hydroxystyryl nonyl ketone, m. 79° . It would appear that dimeric forms are more readily produced when the aldehyde is substituted in the p -position.

C. J. WEST

Chloro- o -xlenols. II. 3-Chloro- o -4-xlenol, the dichloro- o -4-xlenols and 4,5-dichloro- o -3-xlenol. LEONARD E. HINKEL, ERNEST E. AYLING and LILIAN COLLIER BEVAN. Univ. College, Swansea. J. Chem. Soc. 1928, 2529-33; cf. C. A. 18, 384; 22, 3638.—Reduction of 3,4,2-Me₂(PhN₂)₂C₆H₂OH in EtOH with NaHSO_3 gives 3-amino- o -4-xlenol, m. 128° ; through the diazo reaction with CuCl , there results the 3-Cl deriv., m. 27° (Bz deriv., m. 87°). 5-Chloro-3-nitro- o -4-xlenol, by nitrating the Cl deriv., yellow, m. 127.5° ; reduction gives the 3-amino deriv., m. 175° ; through the diazo reaction there results 3,5-dichloro- o -4-xlenol, m. 52° . 6-Chloro-5-benzeneazo- o -4-xlenol, red, m. 143° ; reduction gives 6-chloro-5-amino- o -4-xlenol, m. 144.5° . 5,6-Dichloro- o -4-xlenol, m. 102.5° (Bz deriv., m. 97.5°). 3,6-Dichloro- o -4-xlenol,

m. 84° (*Bz* deriv., m. 124°). 4,5-Dichloro-*o*-3-xylene, m. 90° (*Bz* deriv., m. 133°).

C. J. WEST

Chlorine addition products of toluene. WALTER QVIST. Åbo akademis Institut för Kemisk Teknologi. *Finska Kemistsamfundets Medd.* 37, 45-52(1928).—In the chlorination of PhMe it was found that the HCl liberated was considerably less than the quantity of Cl taken up by the PhMe. Two steam-distn. fractions were removed, 1 with 150 cc. water and the other with 500 cc. The 1st consisted of well-known monochlorotoluenes with pure PhMe. The 2nd fraction was distd. again under a vacuum and on analysis appeared to be a mixt. of tetra- and hexa-Cl compds. with a possible admixt. of a penta-Cl compd. About 47-9% of the Cl was removed by alc. KOH as HCl with the formation of di- and tri-chlorotoluene. Attempts were made to nitrate the di- and tri-Cl compds. in ice with concd. H_2SO_4 and HNO_3 , and analysis showed the presence of trichloronitrotoluene, but no NO_2 compds. of dichlorotoluene were obtained.

HANS C. DUUS

Properties and transformation of *o*-dichloro-4-nitrobenzene. L. McMASTER AND A. C. MAGILL. Washington Univ. *J. Am. Chem. Soc.* 50, 3038-41(1928).—In the nitration of *o*- $C_6H_4Cl_2$ a mixt. of the liquid and solid forms of the 4- NO_2 deriv. (I) is obtained; at 15° the liquid form changes entirely into the solid form, m. 43° ; at 22° about equal quantities of the 2 forms are present. KOH-EtOH and I give mainly 3,3',4,4'-tetrachloroazoxybenzene and small quantities of 3,4- $Cl_2C_6H_3NH_2$ and 2,4- $Cl(O_2N)C_6H_3OH$. With Na alcoholates the corresponding ethers are formed: *Et*, dark brown, m. 142° ; *iso-Pr*, light brown, m. 128° ; *Bu*, brown, m. 136° ; with β - $C_{10}H_7OH$ the diazo solns. from the last 2 compds. give dark red and purple-red dyes, resp.

C. J. WEST

Fluosilicates of some organic bases. C. A. JACOBSON AND H. A. H. PRAY. West Va. Univ. *J. Am. Chem. Soc.* 50, 3055-8(1928).—Fluosilicates of $PhNH_2$, $PhNHMe$, *o*-, *m*- and *p*- $MeC_6H_4NH_2$, consisting of 2 mols. base with 1 of acid have been prepd. The phys. properties of these salts are described and photomicrographs are shown which depict a wholly different cryst. form for each one. The salts crystallize easily from hot EtOH. The $PhNH_2$ salt sublimes unchanged at 230° .

C. J. WEST

Nitration of substituted tertiary aromatic amines. GEO. R. CLEMO AND JAMES M. SMITH. Univ. of Durham, Armstrong College. *J. Chem. Soc.* 1928, 2414-22.—Nitration of 4- $ClC_6H_4NMe_2$ in H_2SO_4 of various concns. gave the following results (the concn. by wt. of the H_2SO_4 and the ratio of 2- to 3- NO_2 compd. in the product are given): 50, 95:5; 70, 85:15; 74.5 to 83.9, 100:0; 86.0, 92:8; 88.3 and 90, an oily product results: 92, 9:91; 93.8 and 98.0, 6:94; 98 (with $CO(NH_2)_2$), 3.5:96.5. $BrC_6H_4NMe_2$ gave the following results: 70, 88:12; 75, 92:8; 79.4, 97:3; 83.9, 92:8; 90, indefinite; 98($CO(NH_2)_2$ present), 4:96. The nature of the *p*-substituent plays an important part in *o*-nitration, since *p*- $MeC_6H_4NMe_2$ gives a good yield of *o*- NO_2 product in dil. H_2SO_4 in the presence of $CO(NH_2)_2$, while nitration in concd. H_2SO_4 gives the *m*- NO_2 deriv. The best explanation of the *o*-nitration is the one which involves the prior addn. of HNO_2 , followed by ionization to give the NH_4^+ ion and the oxidation of the NO to the NO_2 group, which then migrates into an unoccupied *o*-position. The fact that $CO(NH_2)_2$ prevents the reaction when the *p*-substituent is Cl or Br but not when it is Me, CH_2OH , $CH_2C_6H_4NMe_2$ or $C_6H_4NMe_2$ may be ascribed to the more acid character of the 1st 2 bases. 4- $ClC_6H_4NMe_2$ (6.2 g.) in 20 cc. H_2SO_4 , cooled in ice and stirred while a mixt. of 2.9 cc. 66% HNO_3 and 10 cc. 75% H_2SO_4 is run in during 0.5 hr. (temp. $3-5^{\circ}$), the mixt. then allowed to warm to 21° (after 4.5 hrs. a rapid rise to 35° took place), gives 6.5 g. crude 2- NO_2 deriv., m. 56° ; if $CO(NH_2)_2$ is added, 5.8 g. unchanged amine is recovered. 4-Chloro-2-aminodimethylaniline, b₂₅ 158° (*Ac* deriv., m. 90°). Substitution of concd. H_2SO_4 for the 75% H_2SO_4 of the above expt. gives the 3- NO_2 deriv. (7 g.); the same yield of a purer product is obtained in the presence of $CO(NH_2)_2$. The 3-amino deriv., m. 54° (*Ac* deriv., m. 97°). The m. p. curve of the two NO_2 derivs. is given; there is an eutectic at 35° and about 60% of the 2- NO_2 deriv. A similar curve is given for the two NO_2 derivs. of 4- $BrC_6H_4NMe_2$, with an eutectic at about 46° and 67% of the 2- NO_2 deriv. 4-Bromo-2-aminodimethylaniline, b₂₅ 165° (*Ac* deriv., m. 111°). 4-Bromo-3-nitrodimehtylaniline, orange, m. 93.5° . ($Me_2NC_6H_4$)₂CH₂, nitrated in the presence of $CO(NH_2)_2$ in 70% H_2SO_4 , gives the 3,3'-di- NO_2 deriv.; ($C_6H_4NMe_2$)₂ also gives the 3,3'-di- NO_2 deriv. 4,2- $Br(O_2N)C_6H_3NMe_2$ (3 g.) and 52% HNO_3 , first at 10° and then at 35° for 0.5 hr., gives 1 g. of 4-bromo-2,6-dinitrodimehtylaniline, orange, m. 118° . 4- $BrC_6H_4NMe_2$ (1 g.) in 56 cc. 50% H_2SO_4 and 48 cc. H_2O , cooled to 12° and nitrated with 80 cc. 66% HNO_3 and 120 cc. 96% H_2SO_4 , gives 18 g. 4-bromo-2,6-dinitrophenylmethylnitrosoamine, pale yellow, m. 124° ; refluxing with MeOH-HCl for 6 hrs. gives 4-bromo-2,6-dinitromonomethylaniline, orange,

m. 104-5°; heating with fuming HNO_3 10 min. on a water bath gives 4-bromo-2,6-dinitrophenylmethylnitroamine, pale yellow, m. 113-4°; boiling with fuming HNO_3 for 5.5 hrs. gives tetryl. 4- $\text{BrC}_6\text{H}_4\text{NMe}_2$ with 66% HNO_3 and contd. H_2SO_4 gives 4,3,6- $\text{Br}(\text{O}_2\text{N})_2\text{C}_6\text{H}_2\text{NMe}_2$.
C. J. WEST

The oxidation of several tertiary hydrazines. M. GIUA. *Atti accad. sci. Torino* 63, 259-64(1928).—The action of HgO , N_2O_4 and PbO_2 on 2 tertiary hydrazines has been studied. Five g. of 5,2,4- $\text{Me}(\text{O}_2\text{N})_2\text{C}_6\text{H}_2\text{NNMePh}$ (I) in CHCl_3 is boiled with 15 g. HgO for 15 min. The resultant filtrate, a dark red liquid, is treated with petroleum ether and the ppt. recrystd. from EtOH , m. 117-8°; analysis shows it to be 5,2,4- $\text{Me}(\text{O}_2\text{N})_2\text{C}_6\text{H}_2\text{N}_2\text{Ph}$. When treated with N_2O_4 in Et_2O , I gives the same azo compd. as above. The 2,6-dinitro isomer (II) of I with HgO gives a corresponding 5,2,6- $\text{Me}(\text{O}_2\text{N})_2\text{C}_6\text{H}_2\text{N}_2\text{Ph}$, m. 147°, the same product also resulting by the action of N_2O_4 . When II is boiled in CHCl_3 with PbO_2 and the product recrystd. from EtOH the same product is again obtained. Similarly 5,2,4- $\text{Cl}(\text{O}_2\text{N})_2\text{C}_6\text{H}_2\text{NNMePh}$ gives with PbO_2 the corresponding 5,2,4- $\text{Cl}(\text{O}_2\text{N})_2\text{C}_6\text{H}_2\text{N}_2\text{Ph}$, recrystallizable from EtOH , m. 149-50°.
A. W. CONTIERI

The isomers of *p*-hydroxyphenylarsonic acid. GASTON GILTA. Univ. Brussels. *Bull. soc. chim. Belg.* 37, 253-62(1928).—A complete crystallographic examn. of *p*-hydroxyphenylarsonic acid crystals shows that 2 different isomers are obtainable: one is obtained by diazotization of *p*-arsanilic acid, the other by an arsenical fusion of phenol. The formulas proposed are: *p*- $\text{HOC}_6\text{H}_4\text{AsO}_3\text{H}_2$ and $\text{O}:\text{C}_6\text{H}_4:\text{As}(\text{OH})_3$. The crystallographic consts. are recorded, together with those of (*p*- HOC_6H_4) $_2\text{AsO}_2\text{H}$, obtained as by-product. The nitration with HNO_3 (d. 1.4) of the 2 isomers gives 2 forms of 3-nitro-4-hydroxyphenylarsonic acid, differing only crystallographically; no di- NO_2 compd. is obtained. The nitration with HNO_3 (d. 1.5) of either isomer gives only one form of 3,5-dinitro-4-hydroxyphenylarsonic acid.
A. L. KENNE

Attempt to prepare optically active derivatives of quadrivalent tin. FREDERIC B. KIPPING. Univ. of Cambridge. *J. Chem. Soc.* 1928, 2365-72.—As a preliminary to a study of optically active derivs. of Sn, mixed Sn aryls were prepd. and the action of I studied in order to det. the order in which the various groups must be introduced into the mol. so that the desired iodides may be obtained. The ease with which the various groups are removed by I from a mol. contg. 2 or 3 different radicals decreases in the order: *o*- $\text{C}_6\text{H}_4\text{Me}$, *p*- $\text{C}_6\text{H}_4\text{Me}$, Ph, PhCH_2 . (PhCH_2) $_3\text{SnCl}$ and PhMgBr give phenyltribenzylstannane, b_p 290°, does not solidify at 0°; boiling concd. HCl gives C_6H_5 and (PhCH_2) $_2\text{SnCl}$. Tribenzylstannic iodide, from the hydroxide and dil. HI , m. 102-3°; this was also obtained from (PhCH_2) $_3\text{SnPh}$ and I in CCl_4 . Treatment of (PhCH_2) $_3\text{SnCl}$ with 2 mols. I gives (PhCH_2) $_2\text{SnI}$. Triphenylbenzylstannane, b_p 250°, m. 90°; treatment with I in CHCl_3 gives an oil, which could not be crystd.; further treatment with NH_4OH and then with dil. HCl gives phenylbenzylstannic chloride, m. 83-4°, also obtained from $\text{Ph}_2\text{SnCH}_2\text{Ph}$ and concd. HCl . (PhCH_2) $_3$ (*p*- MeC_6H_4)Sn does not solidify at 0°; I gives (PhCH_2) $_2\text{SnI}$; HCl gives (PhCH_2) $_2\text{SnCl}$. Triphenyl-*o*-tolylstannane, m. 165°; I or HCl splits off the *o*- $\text{C}_6\text{H}_4\text{Me}$ group. (*p*- MeC_6H_4) $_2\text{Sn}$ and I in CHCl_3 give (*p*- MeC_6H_4) $_2\text{SnI}$. Tri-*p*-tolyl-*o*-tolylstannane, m. 168°; I splits off the *o*- $\text{C}_6\text{H}_4\text{Me}$ group. Tri-*m*-tolylstannic chloride, m. 108-9°, from the tetra deriv. and I, followed by NH_4OH and HCl . Tri-*m*-tolyl-*p*-tolylstannane, m. 103°; I gives a mixt. of products which could not be purified. Phenyl-di-*p*-tolylbenzylstannane, from PhSnCH_2Ph and *p*- $\text{MeC}_6\text{H}_4\text{MgBr}$, b_p 265-70°; HCl splits off both *p*- MeC_6H_4 groups; I in CHCl_3 gives the oily $\text{Ph}(\text{p}-\text{MeC}_6\text{H}_4)\text{PhCH}_2\text{SnI}$, whose hydroxide m. 136-7°; attempts at resolution gave only oily or amorphous compds. (*d*-camphorsulfonate, *d*-tartrate). Triphenylbutylstannane, b_p 222°, m. 61-2°; boiling HCl gives phenylbutylstannic chloride, m. 50°. Diphenylbenzylbutylstannane, b_p 215°; I in CHCl_3 , followed by NH_4OH , gives phenylbenzylbutylstannic hydroxide, m. 135-7°; fluoride, m. 218°; again the attempts to obtain optically active derivs. resulted in oily or amorphous substances. Dibenzylethylbutylstannane, b_p 195-200°.

Organic bismuth derivatives. FR. FABRYKANT. *Bull. pharm. Inst. Poland*, No. 2, 1-15(1927); cf. *C. A.* 20, 4063, 1984; 21, 2466.—In the search after pharmacol. active compds. the synthesis of trithymylbismuthine and ω -tristyrilbismuthine, $(\text{PhCH}:\text{CH})_3\text{Bi}$, was tried by the Grignard and Marquardt-Michaelis method according to the scheme: $\text{PhCH}:\text{CHCO}_2\text{H} \rightarrow \text{PhCHBrCHBrCO}_2\text{H} \rightarrow \text{PhCH}:\text{CHBr} \rightarrow \text{PhCH}:\text{CHMgBr} \rightarrow (\text{PhCH}:\text{CH})_3\text{Bi}$. ($\text{PhCH}:\text{CH})_3\text{Bi}$ was obtained but in a quantity which did not allow the measurement of phys. consts.
JAROSLAV KUČERA

Unsymmetrical arseno-compounds derived from *p*-arsonophenylaminoethanol and *p*-arsonophenylglycine amide. CHARLES S. PALMER AND ERNEST B. KESTER. North-

western Univ. *J. Am. Chem. Soc.* **50**, 3169–19 (1928).—A series of alkali-sol. unsym. arseno compds. has been prepd. by simultaneous reduction of equimol. proportions of $p\text{-H}_2\text{O}_2\text{AsC}_6\text{H}_4\text{NHCH}_2\text{CONH}_2$ and an arsonic acid contg. a solubilizing group or in which solubilizing groups can be easily substituted. A soln. of 0.02 mol. each of $p\text{-H}_2\text{O}_2\text{AsC}_6\text{H}_4\text{NHCH}_2\text{CH}_2\text{OH}$ (I) and $p\text{-H}_2\text{O}_2\text{AsC}_6\text{H}_4\text{NH}_2$ in 30 cc. H_2O and 10 cc. of 12 N HCl was treated with 0.5 mol. of 50% H_3PO_2 and kept below 15° for 3 days; addn. of 100 cc. cold N HCl ppts. 78% of 4-amino-4'- β -hydroxyethylaminoarsenobenzene-di- HCl , which turns red and gum-like in H_2O but on addn. of a little HCl dissolves readily. The N -methylenesulfoxylic acid results from the di- HCl and NaHSO_3 . I and $\text{H}_2\text{O}_2\text{-AsC}_6\text{H}_4\text{OH}$ give 60% of 4-hydroxy-4'- β -hydroxyethylaminoarsenobenzene- HCl , sparingly sol. in dil. HCl ; the free base is pptd. from alk. soln. by CO_2 . 3-Amino-4-hydroxy-4'- β -hydroxyethylaminoarsenobenzene-di- HCl (53% yield), readily sol. in H_2O or dil. alkali; the N -methylenesulfoxylic acid is formed quant. 4- β -Hydroxyethylaminoarsenobenzene-4'- N -glycine; di- HCl salt, yellow, sol. in NaHCO_3 . 4- β -Hydroxyethylaminoarsenobenzene-4'-oxyacetic acid, yellow, results in 92% yield by first reducing I and then adding $p\text{-H}_2\text{O}_2\text{AsC}_6\text{H}_4\text{OCH}_2\text{CO}_2\text{H}$ and further H_3PO_2 . Reduction of a mixt. of $p\text{-H}_2\text{O}_2\text{AsC}_6\text{H}_4\text{NHCH}_2\text{CONH}_2$ and $p\text{-H}_2\text{O}_2\text{AsC}_6\text{H}_4\text{NH}_2$ by SnCl_2 gives 86% of 4-aminoarsenobenzene-4'- N -glycine amide-di- HCl , not appreciably sol. in H_2O and difficultly sol. in warm dil. HCl , which seems to promote decompn. Reduction of the mixt. with NaHSO_3 gives the corresponding N -dimethylenesulfoxylic acid, yellow (18% yield). 4-Hydroxyarsenobenzene-4'- N -glycine amide- HCl , contains 1 H_2O (67% yield); the free base was also prepd. 3-Amino-4-hydroxyarsenobenzene-4'-glycine amide and di- HCl salt (73% yield); the N -methylenesulfoxylic acid was also prepd. Arsenobenzene-4- N -glycine-4'- N -glycine amide-di- HCl , bright yellow (48% yield), sol. in NaHCO_3 . Tetraarsenobenzene-4- N -glycine-4'- N -glycine amide. Arsenobenzene-4-glycine amide-4'-oxyacetic acid, 67% yield. 4-Hydroxyarsenobenzene-4'-glycine- HCl , sepg. with 1 H_2O (56% yield); 3-amino-4-hydroxyarsenobenzene-4'-oxyacetic acid, 73% yield. 3,4'-Diamino-4-hydroxyarsenobenzene-di- HCl and 4-amino-4'-hydroxyarsenobenzene- HCl were also prepd.

C. J. WEST

Certain aryl arsenoxides and the corresponding dichloro- and diiodo-arsines. GEORGE NEWBERY AND MONTAGUE A. PHILLIPS. May and Baker, Ltd., Wandsworth, Eng. *J. Chem. Soc.* 1928, 2375–81.—5,2-AcNH(HO) $\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$ (C. A. 22, 1337), nitrated in H_2SO_4 at $10\text{--}20^\circ$, gives 80% of 3-nitro-5-acetamido-2-hydroxyphenylarsonic acid, yellow prisms, giving red solns. in alkalis. Reduction of the corresponding NO_2 derivs. gives 60% of the 3-amino-5-acetamido-4- and -2-hydroxyphenylarsonic acids, the former of which is readily sol. in dil. mineral acids and in alkalis, while the latter is sol. only in excess of dil. mineral acids. The 3,5-di-Ac deriv. of the 2-HO acid forms needles, readily sol. in alkali; boiling with 5 parts 15% HCl gives 2,4-(H_2N) $_2\text{-C}_6\text{H}_3\text{OH}$. 3-Amino-5-acetamido-4-hydroxyphenyldichloroarsine- HCl (I), prepd. by SO_2 reduction of the arsonic acid in HCl at room temp., prisms, sol. in dil. alkali; stirring a suspension of 5 g. in 30 cc. H_2O for 30 min. and crystg. the amorphous solid by adding concd. HCl to the NaOH soln., gives the arsenoxide- HCl , prisms, sol. in H_2O after a few secs.' shaking and readily sol. in dil. alkali. The amorphous oxide with HI (d. 1.7) gives the diiodoarsine- HI , prisms, which gives with H_2O the arsenoxide- HI , prisms. Boiling 30 g. I with 120 cc. 5 N HCl and H_2O gives 50% of 3,5-diamino-4-hydroxyphenyldichloroarsine-2 HCl (II), plates, readily sol. in H_2O ; HI transforms this into the diiodoarsine-2 HI , yellow prisms. 3-Amino-5-acetamido-2-hydroxyphenyldiiodoarsine- HI , yellow; the yellow aq. soln. slowly deposits the arsenoxide- HI , prisms. 3,5-Diacetamido-4-hydroxyphenylarsinous acid results by hydrolysis of the dichloroarsine and by acetylation of I or II, plates or needles, sol. in aq. NaOH , Na_2CO_3 or dil. NH_4OH ; it does not lose H_2O at 100° . 3,5-Diacetamido-2-hydroxyphenylarsenoxide, amorphous. 3-Amino-4-hydroxyphenyldiiodoarsine- HI , yellow prisms; about 33% of the I attached to the As atom is removed by hot 8 N HNO_3 ; 25 g. of this compd. in 80 cc. H_2O , treated with 37.5 cc. Ac_2O , gives 3-acetamido-4-hydroxyphenylarsenoxide, prisms, contg. 4 mols. H_2O lost at 100° ; the oxide is sol. in excess of caustic alkalis and in a large excess of NH_4OH . 5-Amino-2-hydroxyphenyldichloroarsine- HCl , prisms, sol. in 4 parts H_2O ; the aq. soln. deposits the arsenoxide- HCl , prisms, which, with HI , gives the diiodoarsine- HI , yellow prisms, giving with H_2O the arsenoxide- HI , prisms. 5-Acetamido-2-hydroxyphenylarsenoxide, anhyd. prisms. 3-Acetamido-4-hydroxyphenyldichloroarsine, needles; the 2-HO deriv., needles, is slowly hydrolyzed to the arsenoxide. 3-Nitro-4-hydroxy-5-aminophenyldiiodoarsine- HI , yellow prisms, giving a yellow soln. in H_2O and red in alkalis; acetylation gives 3-nitro-4-hydroxy-5-acetamidophenylarsenoxide, amorphous, giving deep red solns. in caustic alkalis. 3-Acetamido-4-hydroxyphenylmethoxychloroarsine, in 70% yield from the corresponding arsenoxide

and MeOH-HCl, prisms; the 2-HO deriv. is similarly prepd.; both are readily converted by warm H₂O to the corresponding arsenoxide. 3-Acetamido-4-hydroxyphenylarsine, plates, sol. in excess caustic alkalis, by reduction of the diarseno deriv. with Zn and concd. HCl (90% yield). 5-Acetamido-2-hydroxyphenylarsine, plates; both compds. are readily oxidized by air to the corresponding arseno deriv. C. J. W.

Organic arsenic compounds. XIII. *cycl*-Pentapropylpentaarsine and the thermal decomposition of arseno compounds. WILHELM STEINKOPF* AND HERMANN DUDEK. Techn. Hochschule Dresden. Ber. 61B, 1906-11(1928); cf. C. A. 22, 2373.—It has been shown that, contrary to Auger's statement, the so-called arsenomethane has the mol. formula (MeAs)₅ and it was accordingly formulated as *cycl*-pentamethylpentaarsine (I). I readily polymerizes to a red solid, a property which the Et homolog shows less markedly and it was therefore expected that higher homologs would be still less polymerizable. *cycl*-Pentapropylpentaarsine (II) was accordingly synthesized by prepg. PrAsO₃H₂ according to Quick and Adams and, without isolating the acid, pptg. it as the Mg salt and reducing it directly with NaH₂PO₂; there seps. a viscous yellow oil having the same oxidizability and solubilities as I but, unlike I, showing no tendency to polymerization in the presence of HCl. In a high vacuum it b. 177-9° almost without decompn., but that there is some decompn. is shown by the fact that the distillate, unlike the crude product, shows an oxidizability by atm. air unusual for arseno compds. The impurity (about 5%) is propylcacodyl (III). The mol. wt. of II in freezing PhNO₂ is 563.1-584.1; calcd. for a mixt. with 5% of the cacodyl, 573.5. The formulation as *cycl*-pentaalkylpentaarsines therefore seems to be general for the aliphatic arseno compds. This cannot be tested exptly. on still higher homologs as they cannot be purified by distn. because their decompn. ps. lie below their b. ps. even in a high vacuum. On distn. in a H₂O vacuum the crude II yields metallic As and III, b₁₃ 165-7°, identified by its conversion with I and MeI into dimethyldipropylarsonium triiodide (IV). II therefore decompn. according to the scheme 4II → 5III + 10As, and as its b. p. in a H₂O vacuum must be about 250° the decompn. must already occur at this temp. I at 270° under atm. pressure likewise decompn. into As and cacodyl, b. 155-64°. Finally, arsenobenzene undergoes the same decompn. into As and phenylcacodyl when slowly heated above its m. p. up to 255°. No attempt was made to isolate the cacodyl, but the resulting dark cake, which oxidizes in the air with evolution of heat, was dissolved in dil. HNO₃ and the As detd. with magnesia mixt. as H₃AsO₄; the filtrate on acidification yielded Ph₂AsO₂H. The equation 3(PhAs)₂ = 2Ph₃As + 4As given by Michaelis and Schäfer must therefore be corrected; the tertiary arsine is formed only secondarily from the cacodyl. XIV. Firmness of attachment of hydrocarbon residues to arsenic. WILHELM STEINKOPF, HERMANN DUDEK AND SIEGFRIED SCHMIDT. Ibid 1911-8.—It was found in a series of earlier investigations that tertiary arsines form with BrCN solid addn. products which, unlike those of tertiary amines, decomp. only at high temps. into alkyl bromides and secondary arsine cyanides. From the relative ease with which this decompn. occurs it was found that Me is less firmly attached to As than Et, Pr and Ph, Et less than iso-Bu and Ph, and Et and Pr about equally firmly. The iso-Am and cyclohexyl groups have now been studied; the former is held with about the same firmness as Me, the latter more firmly than Me or Pr and less than Ph. Methyl-diisoamylarsine (116 g. from 250 g. iso-AmCl and 57 g. Mg in Et₂O with 125 g. MeAsCl₂), b₁₁ 95-9°. With Cl in petroleum ether 93 g. gave an oily dichloride, which on distn. in CO₂ began to decomp. 186°; it was finally heated to 210°, giving 24.5 g. iso-AmCl, while from the residue were isolated methylisoamylchloroarsine, b₁₁ 68-72°, and 24 g. of diisoamylchloroarsine, b₁₁ 114-22° (the supposed 6(C₆H₁₁)₂AsCl[(C₆H₁₁)₂As]₂O, b₁₃ 148°, of Dehn and Wilcox (Am. Chem. J. 35, 49(1906)), was probably the above (iso-Am)₂AsCl contaminated with (C₆H₁₁)₃As. Tricyclohexylarsine (45 g. from 118.5 g. C₆H₁₁Cl and Mg with 35 g. AsCl₃), b₁₁ 208-15°, solidifies 41-0°. When it is satd. in CCl₄ with Cl and the cryst. perchloride is heated in vacuo it gives 70% dicyclohexylchloroarsine, b₁₀ 168-71°, converted by 10% Na₂CO₃ into the oxide, faintly yellowish, very viscous mass. Cyclohexyldichloroarsine (12 g. from 21 g. of the (C₆H₁₁)₂AsCl with Cl in petroleum ether), b₁₃ 122-5°. (C₆H₁₁)₂AsPh is obtained in 93% yield from C₆H₁₁MgCl and PhAsCl₂; with Cl in petroleum ether it gives 73% cyclohexylphenylchloroarsine, b₁₃ 183-4°; oxide, viscous, faintly yellowish oil, cannot be distd. without decompn. even in a high vacuum. Cyclohexylphenylarsine cyanide (4 g. from 10 g. Me(C₆H₁₁)AsPh and BrCN in petroleum ether at -20° and subsequent heating to 150°, or 14 g. from 22 g. Ph(C₆H₁₁)AsCl and KCN in H₂O at 60°), b₂ 156.5°, b₁ 190-2°; the intermediate bromocyanide, allowed to stand in moist ether in the air, gives methylcyclohexylphenylarsine oxybromide, thick oil (picrate, yellow, m. 132.5-3°). Propyldijodoarsine (55% from 145 g. PrAsO₃Mg and KI in HCl with SO₃), red-yellow oil,

b_{11} 136–7°, has a fainter odor than the lower homologs but is strongly irritating; oxide, faintly yellowish, b_{11} 142–5°, does not solidify at -20° . *Dipropylidoarsine* (63.4 g. from 187 g. PrAsI_2 and 75 g. PrBr in NaOH), $b_{12.5}$ 103.5–6°, yellow oil, very irritating to the mucous membranes. *Dipropylcyclohexylarsine* (60% from $\text{C}_6\text{H}_{11}\text{MgCl}$ and Pr_2AsI), b_{11} 126.5–9.5°. *Propylcyclohexylarsine cyanide* (3.9 g. from 8 g. $\text{Pr}_2\text{AsC}_6\text{H}_{11}$ and BrCN at 20° , with subsequent heating to 150°), b_1 108.5–10°. *Dipropylcyclohexylarsine oxybromide*, m. 64–7°. *Propylcyclohexylchloroarsine* (2.2 g. from 8 g. $\text{Pr}_2\text{AsC}_6\text{H}_{11}$ and Cl in petroleum ether), b_{16} 131–2°; the intermediate *dipropylcyclohexylarsine dichloride*, m. about 40° and decmps. only at a bath temp. of about 200° .

C. A. R.

Influence of solvents on the rotation of optically active compounds. XXV. Bornyl benzene- and naphthalenesulfonates in various solvents. THOMAS S. PATTERSON AND IRENE MARY MCALPINE. Univ. of Glasgow. *J. Chem. Soc.* 1928, 2472–4; cf. *C. A.* 21, 1642.—The sp. rotations of *l*-bornyl naphthalene- β -(I) and α -sulfonates (II) and of the benzenesulfonate (III) are given for λ 5790, 5461 and 4358 in EtOH , C_6H_6 , $\text{C}_6\text{H}_5\text{N}$, $\text{C}_2\text{H}_5\text{Br}_2$, PhNO_2 and quinoline. The rotations vary considerably in each case with change of solvent. * I has the lowest rotation values except for the soln. in $\text{C}_2\text{H}_5\text{Br}_2$, which overlaps some of the values for other esters. The rotations of the other 2 esters in the different solvents overlap each other completely, the range of variation being greater, however, with II than with III. The different solvents do not influence the rotations in the same way, although there are resemblances. Quinoline produces the highest rotation in II and in III and the 2nd highest in I. In $\text{C}_2\text{H}_5\text{Br}_2$, I shows the highest rotation and II and III the 2nd highest. PhNO_2 produces the lowest rotation in I and III and the 2nd lowest in II. The dispersion coeffs. for these compds. are practically the same.

Mobility of symmetrical triad(prototropic) systems. III. Three-carbon prototropy in an α,γ -diphenylallyl ether. CHARLES WM. SHOPPEE. Univ. of Leeds. *J. Chem. Soc.* 1928, 2567–71.— $\text{PhCH}(\text{OH})\text{CH}:\text{CHPh}$ (15 g.) in glacial AcOH , treated with 75 g. of 30% HBr-AcOH and stirred 2 hrs., gives 13 g. *bis- α,γ -diphenylallyl ether*, m. 98–9°; *tetra-Br deriv.*, pale yellow oil. With O_3 the ether yields BzH and BzOH . Refluxing the ether with EtONa for 2 hrs. gives *bis- α,γ -diphenylpropenyl ether*, yellow oil, decomp. on distn. *in vacuo*; Br in CHCl_3 gives a *di-Br deriv.*, which quickly decolorizes KMnO_4 ; the structure of the ether was confirmed by the action of O_3 , $\text{PhCH}_2\text{-CHO}$ and BzOH being formed. The position of equil. in hot EtOH-EtONa favors the 2nd ether very largely and it thus appears that the combined electronic affinities

(inductive effect) represented in $\begin{array}{c} \text{Ph} \\ \diagup \\ \text{C(H)C:C} \\ \diagdown \\ \text{RO} \end{array}$ are sufficient to produce (under

the catalytic conditions mentioned) tautomeric mobility in a 3-C system which is of a particularly simple type, since it is not implicated in a "developed" keto-enol complex. *Ph β -phenylethyl ketone semicarbazone*, m. 144° .

Reduction of hydroxyazo compounds to aminophenols by means of phenylhydrazine. II. 5-Aminosaligenin and its oxidation by means of phenylhydrazine. GRUSEPPE ODDO AND ANTONINO GIACALONE. R. Univ. Palermo. *Gazz. chim. ital.* 58, 290–7(1928).—In all previous work on the reduction of hydroxyazo compds. to aminophenols (cf. *Gazz. chim. ital.* 35, ii, 598(1905); 36, ii, 87, 305(1906); Puxeddu, *C. A.* 2, 1444; 10, 2882); the reaction is so energetic that the aminophenols are formed immediately. In the present work, attempts were made to control the reactions with the object of isolating intermediate products. A new method for the prepn. of benzeneazosaligenin (I) (cf. *Ann.* 251, 184) is described; PhN_2Cl (from 4.65 g. PhNH_2 , 3.45 g. NaNO_2 and 5 g. of 36% HCl) is added with agitation to ice-cold saligenin (5.4 g.) and the mixt. acidified with dil. HCl , which ppts. a good yield. It m. 145° , and gives a brown-red color in concd. H_2SO_4 , a red resinous powder being pptd. when this soln. is poured in water. I refluxed 10 hrs. with excess Ac_2O and a little NaOAc , cooled, poured into water, the pptd. oil neutralized with soda, let stand overnight, and the cryst. mass recrystd. from ligroin, yields the *di-Ac deriv.* (II) of I, orange-yellow, m. 54° . I (1 g.) in $\text{C}_6\text{H}_5\text{N}$ let stand 6 hrs. with AcCl (0.7 g.), poured into dil. H_2SO_4 , the pptd. oil made alk. with NaOH , let stand, and the cryst. mass recrystd. from ligroin, yields II. Cold I in $\text{C}_6\text{H}_5\text{N}$ let stand 8–10 hrs. with BzCl , poured into dil. H_2SO_4 , neutralized with soda, let stand 24 hrs. and the mass recrystd. from ligroin, yields the *di-Bz deriv.* (III) of I, orange-red, m. 120° . III (0.5 g.) let stand 2 days with cold alc. KOH , dild. with water, filtered, a current of CO_2 passed through the filtrate, the mixt. let stand overnight and the cryst. mass recrystd. from C_6H_6 , yields I. I (1 g.) heated slowly up to $140\text{--}5^\circ$ with PhHNNH_2 (1.5 g.), a little

C_6H_6 added while the mixt. is still warm, filtered and washed with C_6H_6 , yields 0.25–0.30 g. of *aminosaligenin* 2,5- $HO(H_2N)C_6H_3CH_2OH$ (IV), grayish white, m. 139° , dissolves in acids and alkalis, in the latter case the solns. turning brown on exposure to air, can be diazotized. IV (1 g.) in C_6H_5N (6 g.) let stand 20 hrs. with $BzCl$ (3 g.), poured into dil. H_2SO_4 , filtered and the residue recrystd. repeatedly from $CHCl_3$ or $EtOH$, yields the *tri-Bz deriv.* of IV, $BzC_6H_4(OBz)CH_2OBz$, m. 187° . When let stand overnight, the C_6H_6 mother and wash liquors from the prepn. of IV deposit a product which, boiled with water and recrystd. from C_6H_6 , yields 0.1–0.15 g. of 5-aminosalicylic aldehyde phenylhydrazone, 2,5- $HO(H_2N)C_6H_3CH:NNHPh$ (VI), light yellow, m. 165° . Its compn. was established by various phys. and chem. properties (cf. Puxeddu, *C. A.* 10, 2882). PhN_2Cl (from 4.7 g. $\bullet PhNH_2$, 3.5 g. $NaNO_2$ and concd. HCl) added slowly to ice-cold $o-HOC_6H_4CHO$ (6.1 g.) in water (300 cc.) contg. $NaOH$ (6 g.), added to water (1 l.), let stand, acidified with dil. HCl , filtered, the mother liquor let stand overnight and the ppt. recrystd. from dil. $EtOH$, yields benzeneazosalicylic aldehyde (VI), m. 128° (cf. *Ann.* 251, 182; *Ber.* 33, 1325(1900); \bullet Puxeddu, *C. A.* 10, 2882). VI (1 g.) heated with $PhHNNH_2$ (3 g.), an equal vol. of C_6H_6 added to the oil which is formed, let stand, filtered, the residue washed with C_6H_6 and recrystd. from hot C_6H_6 , yields V. $BzCl$ (3.5 g.) added to VI (1 g.) in C_6H_5N , let stand 8 hrs., poured into dil. H_2SO_4 , and after the oil is crystd., the cryst. mass purified with $CHCl_3$, yields the *Bz deriv.* of VI, $C_{24}H_{23}O_4N_3$, m. 265° . The expts. show that by the action of $PhHNNH_2$ on I, IV and VI are formed. A study of various conditions shows that by limiting the proportion of $PhHNNH_2$ and making the reaction proceed rapidly up to $140-50^\circ$, the formation of VI is favored, while by increasing the proportion of $PhHNNH_2$ and maintaining the temp. below 100° , IV is obtained almost exclusively. The best conditions for obtaining IV are to heat I (1 g.) with $PhHNNH_2$ (2 g.) slowly, keeping the temp. below 100° . Since the reaction of I and $PhHNNH_2$ is so rapid and energetic, and N is evolved, atm. O plays no part. The oxidation is attributed to the $PhHNNH_2$, which acts simultaneously as an oxidizing agent and reducing agent, the $-N:N-$ group being reduced and the CH_2OH oxidized.

C. C. DAVIS

Oxidation of alcohols by means of phenylhydrazine. GIUSEPPE ODDO AND ANTONINO GIACALONE. Reale Univ. Palermo. *Gazz. chim. ital.* 58, 298–300(1928) — In previous expts. (cf. preceding abstr.) an instance is shown where $PhHNNH_2$ is an oxidizing agent. Aside from this, only one other case is known, viz., the formation of osazones from monosaccharides (cf. *Ber.* 17, 519(1884); 20, 82(1887); 23, 2117(1890)). In the present paper it is shown that $PhHNNH_2$ oxidizes other aromatic alcs., forming the phenylhydrazone of the corresponding aldehydes. 2,5- $HO(H_2N)-C_6H_3CH_2OH$ (0.5 g.) heated up to 150° with $PhHNNH_2$ (0.7 g.), C_6H_6 added while still hot, the C_6H_6 layer decanted from uncombined 2,5- $HO(H_2N)C_6H_3CH_2OH$, let stand overnight, the cryst. mass washed with cold C_6H_6 , purified with boiling water and recrystd. from hot C_6H_6 , yields 2,5- $HO(H_2N)C_6H_3CH:NNHPh$. $o-HOC_6H_4CH_2OH$ (0.5 g.), heated 5–10 min. at 160° with $PhHNNH_2$ (1 g.), cooled, and the cryst. mass recrystd. several times from dil. $EtOH$, yields $o-HOC_6H_4CH:NNHPh$, m. 142° . With $PhCH_2OH$ the reaction is much slower. $PhCH_2OH$ (1 g.) heated 1 hr. at $180-90^\circ$ with $PhHNNH_2$ (1 g.) and dil. $EtOH$ added, gives only a trace of ppt. Heated at $180-90^\circ$ for 3 hrs. and let stand overnight and dil. $EtOH$ added, it yields 0.15 g. of $PhCH:NNHPh$, m. 155° . $PhCH:CHCH_2OH$ (1 g.) heated 15–20 min. at $180-200^\circ$ with $PhHNNH_2$ (1.6 g.), let stand overnight at room temp., dil. $EtOH$ added and the cryst. mass recrystd. from ligroin, gives a very small yield of $PhCH:CHCH:NNHPh$, m. $167-8^\circ$. Longer heating does not increase the yield; in fact heating for 2–3 hrs. gives almost no yield. The best yields were therefore obtained with HO alcs., and the very low yield from $PhCH:CHCH_2OH$ perhaps depends upon the presence of the double bond in the lateral chain.

C. C. DAVIS

Equilibrium in the binary systems: cresols-amines. NIKOLAI ANTONOVITCH PUSHIN AND LJUBEVIT SLADOVIĆ. Univ. of Zagreb. *J. Chem. Soc.* 1928, 2474–83. — The following data are given for each mixt. studied: the temp. of complete melting of the crystd. mixt.; the complete cooling curve; the duration of the eutectic crystn. $o-MeC_6H_4OH$ (I)- $PhNMe_2$ (II) forms an equimol. compd. m. -6° ; the 2 eutectics correspond to 40 mols. % II (at -9°) and 70% II (at -14°). $p-MeC_6H_4OH$ (III)-II gives 1 eutectic at 50 mols. % and -35° . $I-p-MeC_6H_4NH_2$ (IV) and II-IV each form equimol. compds. m. 38° and 20.5° , resp.; in the 1st system the eutectics are at 22 and 72 mols. % of IV and 14° and 25.6° and in the other system at 32 and 65 mols. % and 12.1° and 16.4° . $m-MeC_6H_4OH$ (V)-IV gives 2 eutectics at 22 and 56 mols. % IV and -14° and 12° . I-quinoline (VI) forms 2 compds., VI.2I, m. 34.5° , and VI.I, m. 34.2° ; 2 eutectics are at 15 and 88 mols. % VI and 20° and -24° , resp. III-VI

also gives 2 compds., III.VI, m. 31.8°, and 2III.VI, m. 24.5°; 2 eutectics are at 20 and 90 mols. % VI and 16° and -23°, resp. III-piperidine forms a compd. $C_8H_{11}N \cdot 2C_7H_7OH$, m. 42.1°; the eutectics are at 15.5 and 72 mols. % of piperidine (14° and -34°). III-1,5- $C_{10}H_8(NH_2)_2$ shows a eutectic point at 10 mols. % $C_{10}H_8(NH_2)_2$ and 29° and a transition point at 33 mols. % and 118°.

C. J. WEST

Optical investigations on quinones and free radicals. STEFAN GOLDSCHMIDT AND FRITZ GRAEF. *Techn. Hochschule, Karlsruhe. Ber. 61B, 1858-69(1928).*—The ordinary formulation of quinones as unsatd. diketones is no complete expression of their properties and other structures have been suggested for them, as, e. g., that of isomeric aroxyls. It was hoped that new light might be thrown on this question by optical investigation. The properties of quinones, especially *o*-quinones, suggest that in solns. they may be present in tautomeric or polymeric forms in equil. with each other: $I \rightleftharpoons 2II$; $I \rightleftharpoons 2III$; $IV \rightleftharpoons III$; $IV \rightleftharpoons II$; $II \rightleftharpoons III$. Beer's law was found,

both colorimetrically and spectroscopically, to hold for solns. of *o*-quinone (V), so that equil. of the 1st two types (between dimeric and monomeric forms) is excluded. Spectrophotometric comparison of V with *p*-quinone (VI) showed that the only similarity which can be established with any certainty is the max. for VI at 4700 Å. U. and for V at 5800; these bands may therefore be ascribed to the 2 keto groups. The absorption curves for homo-*o*-quinone (VII) and *o*-naphthoquinone (VIII), on the other hand, show the close relationship of these substances to V; below are, resp., the position (λ) and height ($\log \epsilon$) of 2 bands for these compds.: V, 5800, 1.4; 3650, 3.35. VII, 5750, 1.35; 3750, 3.25. VIII, 5350, 1.50; 3900, 3.35. The solvent has a pronounced influence on the absorption of all the *o*-quinones studied. The positions and heights of the 2 max. in different solvents are as follows: In hexane: V —, —; 3630, 3.45; VII —, —; 3655, 3.31; VIII, soly. too small to permit of measurements. In Et_2O : V, 5790, 1.40; 3660, 3.37; VI, 5750, 1.35; 3760, 3.28; VIII, 5350, 1.50; 3900, 3.35. In CHCl_3 : V, 5685, 1.48; 3750, 3.23; VI, 5650, 1.50; 3820, 3.24; VIII, 5200, 1.80; 4050, 3.35. If the quinones were true aroxyls it would be expected, on the basis of the results obtained with other radicals contg. univalent O (see below), that at least a part of their ultra-violet spectrum would be similar to that of the corresponding hydroquinone, but such was not found to be the case with VI and homopyrocatechol. On the other hand, the considerable influence of the solvent on the absorption of the *o*-quinones, especially as compared with the hydroquinones, makes probable the existence of equil. of the type mentioned above, but comparison of the height of the quinone bands in the visible spectrum with that of the chlorophenanthroxyl bands makes it appear quite certain that even in the *o*-quinones the part present in the aroxyl form can be only very small and is even smaller in the *p*-quinones. Like VI, V decolorizes Ph_3C with formation of the ether $\text{C}_6\text{H}_4(\text{OCPh}_3)_2$, which, because of its instability, does not cryst. but on long treatment with air splits off all the Ph_3C again as the peroxide. The ultra-violet spectra of 2,4,6- $(\text{O}_2\text{N})_3\text{C}_6\text{H}_2\text{NHNPh}_2$ and the corresponding stable, wholly monomol. hydrazyl $(\text{O}_2\text{N})_3\text{C}_6\text{H}_2\text{NPh}_2$ differ from

each other hardly more than those of V in 2 different solvents; only in the visible region does there appear in the spectrum of the hydrazyl an extraordinarily high ($\log \epsilon$ 3.81) flat band; the change of N from the ter- to the bivalent state therefore affects the absorption only in the visible region. The slow dissociation of 9-chloro-10-phenanthryl peroxide (IX) in solvents into the anthroxyl permits of measuring the spectrum of the peroxide by working rapidly, and that of the equil. soln. can be detd. after adding $\text{C}_6\text{H}_5\text{N}$ (although only in the visible region, because of the considerable absorption of $\text{C}_6\text{H}_5\text{N}$ in the ultra-violet). Like the hydrazyl, the anthroxyl shows a broad, very high band throughout a large part of the visible region. At the concns. used ($M/4600$ and $M/13,650$) there were still equil. between the peroxide and aroxyl, measured by titration with $(\text{PhNH})_2$ (α_{4600} 0.655, α_{13650} 0.898), and Beer's law consequently does not hold; that it does not is shown by the powerful influence of the concn. on the height of the extinction curves. IX in CHCl_3 contg. a few % of $\text{C}_6\text{H}_5\text{N}$ allowed to stand with an excess of VI in CHCl_3 yields a substance, $\text{C}_{14}\text{H}_{18}\text{O}_4\text{NCl}$, yellow, m. 195°.

C. A. R.

Reduction of *p*-dimethylaminobenzaldehyde and the preparation of *p*-dimethylaminobenzyl alcohol. GEORGE R. CLEMO AND JAMES M. SMITH. Univ. of Durham,

Newcastle-upon-Tyne. *J. Chem. Soc.* 1928, 2423-6.—*p*-Me₂NC₆H₄CHO (10 g.) in 50 cc. EtOH, treated with 150 g. 4% Na-Hg and refluxed 4 hrs., gives, on diln. with 250 cc. H₂O, filtration, and extr. with Et₂O, 1.6-1.8 g. *p*-dimethylaminobenzyl alc., b₁ 123°; Bz deriv., m. 91°; *m*-nitrobenzate, pale yellow, m. 76°; methiodide, m. 232° (decompn.); chloroplatinate, pale brown, crystg. with 2 EtOH, m. 100° (decompn.). I is a mixt. of 2 stereoisomeric sym-bis[*p*-dimethylaminophenyl]ethylene glycols; 23.4 g. I, extd. with Et₂O, gives 8 g. of a solid, C₁₈H₂₄O₂N₄, m. 178°; methiodide, m. 232° (decompn.); the Et₂O filtrate gives 15 g. of a compd. m. 113°, whose dimethiodide, crystals with 1 EtOH, m. 97° (decompn.). Electrolytic reduction of *p*-Me₂NC₆H₄CHO gives a mixt. of at least the 4 following compds.: *p*-Me₂NC₆H₄Me, 15%; *p*-Me₂NC₆H₄CH₂OH, 20%; CH₂(C₆H₄NMe₂)₂, and the above glycol, m. 178°; it has not been possible to isolate the glycol, m. 113°, although it is probably formed. C. J. WEST

Dependence of rotatory power on chemical constitution. XXXII. Resolution of phenylbenzylcarbinol. WM. GERRARD AND JOSEPH KENYON. Battersea Polytechnic. *J. Chem. Soc.* 1928, 2564-7; cf. C. A. 21, 1253.—Phenylbenzylcarbinyl H phthalate (I) and quinine in Me₂CO give the insol. *d*-salt, m. 205° (decompn.); decompn. with HCl gives the *d*-I, m. 131°, [α]_D²⁵ 32.75°, [α]_D²⁵₅₄₆₁ 38.75° (EtOH, c 5). The more sol. fractions of the quinine salt, decompd. with HCl and the ester treated with cinchonine, give a *l*-salt, m. 110° [α]_D²⁵₅₄₆₁ 82.3° (EtOH, c 4.90); decompn. gives the *l*-I, m. 131°, [α]_D²⁵₅₄₆₁ -38.80° (EtOH, c 5). Alk. sapon. gives the *d*- and *l*-phenylbenzylcarbinols, m. 67°. The *d*-compd. has d_D¹ 1.0358, 1.0251, 1.0210, 1.0152, 1.0095 and 1.0031 at 70, 86, 92, 100, 110 and 120°, resp., and α_D¹₅₄₆₁ 6.51, 8.68, 12.92, 16.57, 20.40, 25.40, 31.82 and 67.1° at 125, 115, 100, 90, 80, 70, 60 and 20°, resp. Values are also given for 4358, 5780, 5893, 6708 and for solns. in C₆H₅N, CHCl₃, CS₂, C₆H₆, CCl₄, Me₂CO, EtOH at 25° and for EtOH at 17° and for *d*-I in Me₂CO, C₆H₆, CHCl₃ and EtOH at 25°. *l*-Phenylbenzylcarbinyl acetate, b₁₈ 182°, d_D¹ 1.0831, 1.0723, 1.0552, 1.0380, 1.0214, 1.0041, 0.9958 and 0.9870 at 17, 30, 50, 70, 90, 110, 120 and 130° resp., [α]_D¹₅₄₆₁ 43.81, 43.09, 42.02, 40.33, 38.06, 35.15, 31.09 and 28.00° at 130, 120, 110, 90, 80, 50, 30 and 17°, resp.; values are also given for 4358, 5780, 5893, 6708 at the same temps. The effect of temp. on the *d*-alc. is very great, there being a 10-fold increase on cooling from 125° to 20°; at the same time the rotatory dispersion ratio α₄₃₅₈/α₅₄₆₁ changes from 2.57 at 125° to 1.79 at 20°. The effect of solvents on the rotatory power is also very pronounced, the value of [α]_D²⁵₅₄₆₁ changing from -11° in C₆H₅N to 64.1° in EtOH, while in C₆H₆ the rotatory dispersion is anomalous. C. J. WEST

Certain mixed esters of alcohols used in perfumes. P. SCHVING AND S. SABETAY. *Bull. soc. chim.* 43, 857-9 (1928).—The following mixed carbonates were prepd. almost quant. by the reaction in CHCl₃ between alkyl chlorocarbonates and other alcs. in the presence of pyridine: rhodinyll Me, b₁₉ 137-8°, n_D¹⁸ 1.4510; cinnamyl Me, b₁₉ 158-61°, n_D¹⁸ 1.5356; phenylethyl Me, b₁₉ 133-4°, n_D¹⁹ 1.4940; phenylethyl Et, b₁₇ 140-1°, n_D²² 1.4889, d₂₂ 1.063; benzyl Et, b₂₀ 122-4°, n_D²⁴ 1.4899, d₂₄ 1.084; cinnamyl Et, b₁₈ 164-6°, n_D²⁴ 1.5214; anisyl Et, b₁₆ 166-7°, n_D²³ 1.5010; geranyl Et, b₁₇ 145-8°, n_D²¹ 1.4530; citronellyl Et, b₁₈ 141-2°, n_D^{20.5} 1.4426, n_D²² 1.4420; phenylethyl allyl, b₁₇ 152-152.5°, n_D²⁰ 1.4936, d₂₀ 1.060; cinnamyl allyl, b₁₈ 176-8°; geranyl allyl, b₁₈ 157.5-158°; diphenylethyl, b₂ 190°, m. 56°; rhodinyll phenylethyl, b₂ 191°, n_D²¹ 1.5010; cyclohexyl phenylethyl, b₁₉ 194°, n_D¹⁸ 1.5070. Allyl chlorocarbonate, b₇₆ 110-1.5°, and phenylethyl chlorocarbonate, b₁₈ 120°, n_D²¹ 1.5110, were obtained in yields of 63 and 86%, resp., by the action of COCl₂ in a freezing mixt. The linalyl Et ester, b₁₈ 127-8°, n_D²² 1.4508, could not be obtained as above but was obtained by the action of EtOCOCl on Na linalylate in Et₂O. C. H. PEET

Aldehyde synthesis with the aid of iron pentacarbonyl (preliminary communication). HANS WOLF. Univ. Frankfurt a. M. *Ber.* 61B, 1765-6 (1928).—In the Gattermann aldehyde synthesis HCOCl is an intermediate product but its formation from HCl and CO occurs only in the presence of substances, such as CuCl, which render possible the intermediate formation of a complex of CO. It seemed logical to start with a preformed CO complex such as Fe(CO)₅, and as a matter of fact 13-6 g. pure *p*-MeC₆H₄CHO, b. 204°, is obtained from 17.5 g. Fe(CO)₅, 30 g. PhMe and 45 g. AlCl₃ at 40-5° treated 3 hrs. with a rapid current of carefully dried HCl gas. C. A. R.

Conditions determining the thermodynamic stability of cyanohydrins of carbonyl compounds. I. Some effects (a) substitution in aromatic aldehydes and (b) ring

formation. ARTHUR LAPWORTH AND RICHARD H. P. MANSKE. Univ. of Manchester. *J. Chem. Soc.* 1928, 2533-49.—The consts. for the dissociation $\text{RC(OH)(CN)R}' \rightleftharpoons \text{RCOR}' + \text{HCN}$ of a no. of cyanohydrins (I) derived from aldehydes and ketones have been detd. in 96% EtOH at $20 \pm 0.5^\circ$. The dissociation consts. of I derived from BzH and its substitution derivs. appear to be affected by the same factors which influence the ionization consts. of BzOH and its substitution derivs., although the "electropolar" factor appears to be of relatively less importance in the *p*-substituted I and the "quant." factor has little if any influence in the *m*-substituted I. The effects of *o*-substituents examd. (other than HO) are such as to depress the dissociation consts. of the I and this in direct contrast to the result to be anticipated from the classical "space-occupation" hypothesis so frequently used to account for other effects associated with *o*-substitution. Ring closure (with elimination of 2 atoms of H) in a chain comprising a CO-C atom leads sometimes to a large increase and sometimes to a large decrease in the dissociation const. of the derived I. The results obtained are discussed from the point of view of the electronic theory and it is suggested that possibly the additive capacity of a CO-C and $\text{C}_2\text{H}_4\text{-C}$, considered from the standpoint of entropy, does not increase continuously with the restraint on its electrons but reaches a max. and then declines, just as in the series B, C, N, O, the capacity to form stable compds., in which the element exercises a coördination no. of 4, attains a max. at C.

C. J. WEST

Syntheses starting from isopropyl phenyl ketone. JOSEPH BLONDEAU. *Bull. soc. chim.* 43, 343-6 (1928).—BzCHMe₂ boiled in dry C₆H₆ with NaNH₂ followed by BuI gave 81% of 1-phenyl-2,2-dimethyl-1-hexanone, b. 268° , b₃₃ 160° , split by NaNH₂ in boiling PhMe (followed by treatment with H₂O) to give 72% of α, α' -dimethylcaproic amide (I), m. 92° . Reduction of I with Na in abs. alc. gave 15% 2,2-dimethyl-1-hexylamine, b₂₄ $63-5^\circ$ (chloroplatinate); and 31% 2,2-dimethyl-1-hexanol, b₂₉ 95° ; acetate, liquid; phenylurethan, m. 52° . Similarly, BzCMe₂C₈H₁₇ yielded 50% of α, α' -dimethylcapric amide, b₁₈ 205° , m. 92° , from which 30% of 2,2-dimethyl-1-decanol, b₁₉ 134° , was obtained.

B. H. NICOLET

Absorption spectra of derivatives of acetophenone. TOMOKICHI TASAKI. *Acta Phytochim.* 3, 259-315 (1927); cf. *C. A.* 20, 1030.—Curves are given for spectra of 65 substances related to AcPh, and conclusions summarized in 3 pp. which cannot be abstracted. The following new compds. are described: reduction with Pt black in AcOH of the corresponding chalcones gave the following benzylacetophenones: 2',4',5'-tri-Me (from Me₃C₆H₂COCH:CHPh), m. $37-8^\circ$; 4-Me, m. $48-50^\circ$; 2'-HO, m. $36-7^\circ$; 3'-HO, m. $40-2^\circ$; 4'-HO, m. $62-4^\circ$; 3-HO, m. $73-4^\circ$; 3-methoxy-4-ethoxy, m. $654-5^\circ$; 2-hydroxy-4'-methoxy, m. $59-60^\circ$; 3-methoxy-4,4'-diethoxy, m. $70-1^\circ$; 4,3',4'-tri-MeO, m. $65-6^\circ$; 3-methoxy-4,4'-diethoxy-2'-hydroxy, m. $77-9^\circ$; 3,4-methylenedioxy-2'-hydroxy-4'-ethoxy, m. 117° . Claisen condensations yielded ω -acetyl-3,4-dimethoxyacetophenone, m. $71-2^\circ$; 4,4'-dimethoxydibenzoylmethane, m. 114° ; 2-ethoxy-4'-methoxydibenzoylmethane, m. $90-1^\circ$; *p*-MeOC₆H₄COCH₂COCH₂Ph, m. $75-6^\circ$.

B. H. NICOLET

Cleavage of hydrocarbostyryl and its derivatives to [2-aminophenyl] propionic and -butyric acids. FRITZ MAYER, H. PHILIPPS, F. W. RUPPERT AND A. TH. SCHMITT. *Ber.* 61B, 1966-75 (1928); D. R. P. Anmld. d. I.-G. Farbenindustrie in Frankfurt a. M. F 58,556 IV/12q of Apr. 6, 1925.—Aminophenylpropionic and -butyric acids are obtained with relative ease by heating hydrocarbostyryl (I) and its carbo- and heterocyclic substituted derivs. with aq. Ba(OH)₂ at about 150° under pressure. The stability of the Na salts, which were isolated in all cases, varies. Many are stable only in alk. solns., others can be readily recrystd. and obtained in pure form. When the Na salt of *o*-H₂NC₆H₄CH₂CH₂CO₂H (II) is treated with exactly the calcd. quantity of mineral acid, the soln. becomes turbid and after a short time I crysts. out. If the turbid soln. is at once extd. with Et₂O, some II can be recovered from the Et₂O as the Na salt with Na₂CO₃, but the free II itself cannot be isolated. Of the diketoöctahydrophenanthrolines, the cleavage of only the one having the structure

was effected with certainty; it yielded 3,6-diaminophenylene-1,2- β, β' -dipropionic acid (IV), obtained in pure form only as the Bz deriv. The *N*-alkyl derivs. of I likewise

yield the *N*-substituted acids. The following compds. were prep'd.: β -[2-Aminophenyl]propionic acids: unsubstituted (I) (Bz deriv., m. 155-8°), 3-Cl; 5-Cl (Bz deriv., m. 189-92°); 3,5-di-Cl; 3-Me; 5-Me (Bz deriv., m. 170-2°); IV (Bz deriv., m. 274°); 5-MeO (Bz deriv., m. 183-4°). β -[2-Aminophenyl]butyric acid and the 5- and 3-Cl and 3,5-di-Cl derivs. The yields were 50-100%. Cautious acidification of the Na salt of β -[2-methylaminophenyl]propionic acid (V) gave the free V, which, however, changed in 12 hrs. into *N*-methylhydrocarbostyryl (VI). From the Na salts of the corresponding acids were obtained with Me_2SO_4 the esters *o*- $\text{Me}_2\text{NC}_6\text{H}_4\text{CH}_2\text{CH}_2\text{CO}_2\text{Me}$ (VII), *o*- $\text{EtMeNC}_6\text{H}_4\text{CH}_2\text{CH}_2\text{CO}_2\text{Me}$ (VIII) and $\text{PhMeNC}_6\text{H}_4\text{CH}_2\text{CH}_2\text{CO}_2\text{Me}$ (IX). VII and VIII can be sapond. with acids while IX with HCl gives *N*-phenylhydrocarbostyryl (X). The free acids (from the HCl salts with NaOAc) are oily; on distn. *in vacuo* that obtained from VII partially changes into VI, with loss of MeOH, while the one from VIII can be obtained pure. The β -[2-aminophenyl]propionic acids can be indirectly diazotized and the NH_2 group replaced by halogens, CN, H, SH and SO_2H ; boiling of the diazo compd. gives the α -chromanone. Finally, indanones can be obtained by intramol. ring formation with AlCl_3 from the chlorides of the halogen acids obtained by replacing the NH_2 group by halogens. Me β -[2-dimethylaminophenyl]propionate (VII), b_{20} 140°; HCl salt of free acid, m. 183-4°. Me β -[2-methylethylaminophenyl]propionate (VIII), b_{20} 145°; free acid, b_{20} 190° (HCl salt, m. 130-3°). Me β -[2-methylphenylaminophenyl]propionate (IX), b_{18} 200°. The following acids were prep'd. by the Sandmeyer method from the corresponding NH_2 acid; the b. p. and yield of the chloride are given in parentheses: β -Phenylpropionic acids: 2-Cl, m. 97°, 65-70% (b_{20} 135-58°, 90%); 2-Br, m. 98°, 60-5% (b_{18} 160-5°, 75%); 2,3-di-Cl, m. 114°, 55% (b_{28} 178-82°, 60%); 2,5-di-Cl, m. 118°, 50% (b_{18} 154-8°, 95%); 2,3,5-tri-Cl, m. 113°, 50% (b_{12} 201-3°, 90%); 2-chloro-3-methyl, m. 118°, 45% (b_{18} 140-6°, 90%); 2-chloro-5-methyl, m. 93°, 45-50% (b_{18} 160-8° (solidifying in the receiver), 75-80%); 2-chloro-5-methoxy, b_{18} 200°, m. 72-3°, 30% (chloride not isolated). β -Phenylbutyric acids: 2-Cl, b_{18} 150°, m. 60°, 70% (b_{28} 140°, 90%); 2,5-di-Cl, b_{18} 180°, m. 71°, 64% (b_{18} 160°, 85%); 2-bromo-5-chloro, b_{18} 200°, m. 87°, 87% (—); 2,3-di-Cl, m. 115°, 64% (b_{18} 180°, 80%); 2,3,5-tri-Cl, b_{18} 190°, m. 115-6°, 52% (b_{18} 160°, 80%). 1-Keto-2,3-dichloroindenes: 4-Cl, m. 92°, 90%; 4-Br, m. 98-9°; 4,5-di-Cl, m. 88°; 4,7-di-Cl, m. 124°, 85%; 4,5,7-tri-Cl, m. 114°, 75%; 4-chloro-5-methyl, m. 82°, 90-5%; 4-chloro-7-methyl, b_{18} 168-73° (anal. values too high) (oxime, m. 138°); 4-chloro-7-hydroxy (Me split off from the MeO group in its prepn.), m. 122°, 65%; 3-methyl-4-chloro, m. 55°, 76%; 3-methyl-4,7-dichloro, m. 103°, 70%; 3-methyl-4,5-dichloro, b_{18} 170°, m. 44°, 66%; 3-methyl-4,5,7-trichloro, m. 88-9°, 54%. β -[2-Cyanophenyl]propionic acid, m. 136° (50% yield), hydrolyzed by H_2O_2 -NaOH to the 2- CO_2H deriv., m. 165.5°. β -[2-Cyano-5-chlorophenyl]butyric acid, b_{18} 160°, m. 120° (40%); 2-carboxy deriv., m. 185°. 4-Methyl-6-chloro- α -chromanone, b_{18} 145-50°, m. 66°, gives 4-methyl-6-chlorocoumarin at 250° with Br vapor in CO_2 . $\text{PhCH}_2\text{CH}_2\text{CO}_2\text{H}$, m. 49°, is obtained in 70% yield from diazotized II added to Cu powder in boiling alc. β -Phenylpropionic-2-sulfinic acid, from diazotized II satd. in the cold with SO_2 and then treated with Cu powder. β -[2-Mercaptophenyl]propionic acid, from diazotized II added to EtOCS_2K at 70°, then boiled with alc. KOH, freed from the alc. by distn., acidified with dil. H_2SO_4 and distd. with steam in the presence of Zn dust, m. 118° (55%). The acid obtained in the same way from 5,2-Cl(H_2N) $\text{C}_6\text{H}_3\text{CHMeCH}_2\text{CO}_2\text{H}$ loses H_2O on distn. *in vacuo*, giving 50% 4-methyl-6-chlorohydrothiocoloumarin, m. 56°, which with boiling 10% NaOH yields β -[2-mercapto-5-chlorophenyl]butyric acid, m. 81-2°.

C. A. R.

Alkali sulfonates of coumarin and nitrocoumarin. RAJENDRA NATH SEN and DUHKHAHARAN CHAKRAVARTI. Presidency College, Calcutta. *J. Indian Chem. Soc.* 5, 433-7(1928).—The positions of the SO_3H groups in coumarinmono- (I) and -disulfonic acid (II) prep'd. by Perkin (*J. Chem. Soc.* 24, 37), and of the 6-nitrocoumarinsulfonic acid (III) were detd. For this purpose, the ordinary methods were not applicable; alkali fusion, *e. g.*, leading to a rupture in the lactonic ring of the coumarin mol. Therefore the lactonic ring was oxidized with KMnO_4 and known derivs. of *o*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$ (IV) obtained. Thus I was shown to be coumarin-6-sulfonic acid. In III, the SO_3H group occupies a position in the lactone ring and is probably 6-nitrocoumarin-3-sulfonic acid in analogy with 3,6-dinitrocoumarin (*J. Chem. Soc.* 97, 1397), and similarly, II is probably coumarin-3,6-disulfonic acid. Some new derivs. of I, II and III were prep'd. The process of prepg. I, II and III was improved by pptg. the SO_3H acids as the Na salts, and in the case of II, by substituting the ordinary fuming H_2SO_4 by 50% fuming H_2SO_4 . Ten g. coumarin heated with 50 g. fuming H_2SO_4 for 2 hrs. on the water bath, cooled, filtered into satd. NaCl soln. and kept for 1-2 days, gave 85% of the Na salt (V) of I; this salt gave with PCl_5 or POCl_3 the sulfonyl chloride (VI), m. 115°;

from VI were prepd. the *amide*, m. 188°, and the *anilide*, m. 132°. For the oxidation, V was dissolved in 2% KOH and 4% KMnO₄ was slowly added at 0–10°. When the oxidation was complete, the soln. was heated for 1 hr. on the water bath, filtered, concd., and concd. HCl added. The resulting acid K salt of 5,2-HO₂S(HO)C₆H₃CO₂H (VII) was filtered off, recrystd., and converted to the free acid. *Na salt* (VIII) of III, from 10 g. coumarin and 70 g. 50% fuming H₂SO₄ by heating for 3–4 hrs. to 150° on the oil bath, cooling and pptg. with NaCl soln. Recrystn. gives VIII in 70% yield; *disulfonyl chloride*, m. 170–3°; *diamide*, m. above 240°; *dianilide*, yellow. Oxidation of VIII, carried out as in the case of V, leads to formation of VII. *Na salt* (IX) of III, (80% from 10 g. 6-nitrocoumarin and 60 g. 50% fuming H₂SO₄ by heating to 150° for 3–4 hrs. and pptg. with NaCl soln.), yellowish; *sulfonyl chloride*, m. 205°; *amide*, does not m. 260°; *anilide*, m. 130°. The product of oxidation of IX was identified as 5,2-O₂N(HO)C₆H₃CO₂H.

G. SCHWOCH

Thiophthalic acids. I. GOPAL CHANDRA CHAKRAVARTI. *J. Indian Chem. Soc.* 5, 405–10 (1928).—KOH, 12 g., in 125 cc. abs. EtOH, satd. with H₂S in the cold, was added to phthalyl chloride, 15 g. in 75 cc. EtOH. The mixt., after standing overnight in the cold after the initial vigorous reaction, was poured on to ice and the aq. mixt. extd. with Et₂O. The Et₂O ext., washed with H₂O, was extd. with cold Na₂CO₃ soln. A yellow solid, crystals from pyridine, not decompd. at 320°, insol. in Et₂O, EtOH, C₆H₆ and in alkalis, seps. This is supposed to be *diphthalyl disulfide*. The ether ext. is (B). The alk. ext. with HCl gave *dithiodibenzoyl-o,o'-dicarboxylic acid* (I), decomp. about 242°. This gave K and Pb salts. The alk. ext. gave another Pb salt which with H₂S gave *monothiophthalic acid*, decomp. about 198°, sol. in EtOH and Et₂O, oxidized by air to I. The ether ext. (B) on evapn. gave *thiophthalic anhydride*, m. 114° and an oil of undetd. constitution. I was also obtained from the reaction product of *ditolyl dithiophthalate* and KSH in EtOH in a sealed tube at 120°. P. J. C.

Ring formation. II. The constitution of monophthalylbenzidines. ANUKUL CHANDRA SIRCAR AND PREM RANJAN SEN GUPTA. *J. Indian Chem. Soc.* 5, 397–9 (1928); cf. *C. A.* 21, 80, 402.—Monophthalylbenzidine (I) and BzH in PhNO₂ give the *benzylidene deriv.*, m. above 300°, insol. in EtOH, C₆H₆, AcOH or pyridine, but sol. in PhNO₂. With *o*-HOC₆H₄CHO the *salicylidene deriv.*, m. 297°, and with *m*-O₂NC₆H₄CHO the *m*-nitrobenzylidene deriv. m. 280°, are obtained. With β-C₁₀H₇ONa a red dye *phthalyl-4-aminodiphenyl-4'-azo-β-naphthol*, m. 273–5°, was obtained from diazotized I. *Di-p-diphthalylbenzidine*, m. above 300°, was obtained from I and C₆H₄(CO)₂O in boiling PhNO₂. III. The condensation of benzidine with dibasic acid anhydrides. *Ibid* 401–4.—Naphthalic anhydride (I) and benzidine (II) in water under reflux gave naphthalylbenzidine (III), m. above 300°, insol. in C₆H₆, EtOH, sparingly sol. in AcOH, sol. in hot pyridine or PhNO₂, insol. in dil. acids or alkalis, diazotizable and can be coupled with phenols; *benzylidene deriv.*, m. 297°, insol. in C₆H₆, EtOH, AcOH, sol. in pyridine and PhNO₂, easily hydrolyzed; *salicylidene deriv.*, greenish yellow plates, m. 283°, insol. in alkalis; *m*-nitrobenzylidene deriv. yellow hexagonal prisms, m. 299°. I and II at 250° gave *dinaphthalylbenzidine*, m. above 300°, insol. in EtOH, C₆H₆, AcOH, sol. in pyridine and PhNO₂. Camphoric anhydride and II gave *camphorylbenzidine*, m. 190°, sol. in EtOH, sparingly sol. in hot H₂O, dil. acids and alkalis, insol. in Na₂CO₃, condensing with aldehydes, diazotizable and can be coupled with phenols. Quinolinic anhydride (IV) and II gave *p*-aminodiphenylquinolinamic acid, HO₂CC₆H₃CONHC₆H₄C₆H₄NH₂, sol. in dil. acids and alkalis, losing 1 H₂O on crystn. from PhNO₂ to form *quinolinylbenzidine*, m. above 300°. Tolidine with IV gave *p*-aminoditolylquinolinamic acid, m. 231°, which did not give quinolinyltolidine on crystn. from PhNO₂. Diphenic acid with II gave *p*-aminodiphenyldiphenaminic acid, m. 199°, which could not be made to form a 7-membered ring by loss of water. P. J. C.

Further observations on the structure of the terpenes. Pinonene and isodiprene. OSSIAN ASCHAN. *Finska Kemistsamfundets Medd.* 36, 82–9 (1927).—Extensive researches have shown that a large part of the Finnish turpentine b. 160–174°. The portion b. 162–6° is a new compd. hitherto not isolated, which splits into sylvestrene and dipentene after the addn. of HCl. This terpene, which A. called "pinonene," appears to be identical with Simonsen's Δ⁴-carene (cf. *C. A.* 16, 419; 17, 91), while the remainder, b. 168–71°, is Simonsen's Δ³-carene. The fact that S.'s products are found in East Indian trees under conditions quite different from those of Finland, is regarded as of considerable interest from a biochem. standpoint. HANS C. DUUS

Finnish turpentine. VII. Isodiprene, a new terpene of the sylvestrene group. OSSIAN ASCHAN. *Bidrag Till Kännedom af Finlands Natur och Folk.* H.80, No. 6, 18 pp. (1926).—About 60% of the Finnish turpentine b. 160–70°. In the fraction b. 163–7° is an as yet unidentified terpene, tentatively named pinonene. The fraction

b. 167–70° contains a new terpene, isodiprene, closely related to the synthetic product, diprene; it has d_4^{20} 0.8561, n_D 1.47536, M. R. 44.84. It is unsatd. and has a mandelic odor. When distd. with Ac_2O and concd. H_2SO_4 a characteristic reddish violet color is noted. It takes up HCl to give a mono-HCl salt, d_4^{20} 0.9775, n_D 1.48175, mol. refraction 50.57, showing the presence of a double bond. The position of the double bonds in isodiprene has not been established. When the HCl is split off, sylvestrene is formed. Attempts to make a di-HCl salt of isodiprene were not wholly successful. As a result of various theoretical considerations, the terpenes of the sylvestrene group are classified in 3 groups: (1) terpenes which give an intense blue color with Ac_2O and a small quantity of concd. H_2SO_4 ; (2) terpenes which are *m*-menthadienes but give a violet color, which group is characterized by taking up more than 1 mol. HCl only with difficulty; (3) terpenes which are bicyclic and contain the same double ring as carone, consisting of a cyclohexane and cyclopropane ring. These should be intermediate between the sylvestrene and dipentene groups. HANS C. DUUS

The ultra-violet absorption curves of the terpene alcohols in comparison with their constitution. JEAN SAVARD. *Compt. rend.* 187, 540–3(1928).—The absorption curves of butylpulegol, butylisopulegol, dihydrocarveol, α -, β -, γ - and 4-terpineol were studied. All the curves present (a) a max., or a level stretch or a singular point in the range of 2260–2380 A. U.; (b) the 1st part ascends regularly from a band whose max. located in the extreme ultra-violet is not obtained. The (a) portion of the curve corresponds to the existence of a double bond and (b) to an alc. function. R. C. ROBERTS

Decomposition of bornyl benzene- and naphthalenesulfonates by heat. The products of hydrolysis of bornyl and menthyl benzene- and naphthalenesulfonates. The influence of solvents on the temperature of decomposition of these bornyl and menthyl sulfonates. THOMAS S. PATTERSON AND IRENE MARY McALPINE. Univ. of Glasgow. *J. Chem. Soc.* 1928, 2464–72.—Continuing the work reported in C. A. 21, 1642, the authors studied the *l*-bornyl derivs. Menthyl esters of benzene-, naphthalene- α - and - β -sulfonic acids, when distd. under reduced pressure, yield menthene and the corresponding SO_3H acid; but if they are heated for some time before distn., dimenthene and more complex substances are produced, but no menthene. The corresponding bornyl esters, when directly distd., yield camphene, dibornylene, a more complex gelatinous material and SO_3H acid. When heated 2–3 hrs., and then distd., they yield dihydrocamphene, dibornylene, a gelatinous material and SO_3H acid. These esters, heated to boiling in PhMe, yield dibornylene and the corresponding SO_3H acid. These changes may be represented as follows:

The menthyl and bornyl esters of these acids do not hydrolyze to yield menthol and borneol but, on the contrary, decomp. in somewhat the same way as when heated alone. The rate at which these esters decomp. in soln. depends markedly on the nature of the solvent; in the alcs. the velocity increases rapidly as the mol. wt. diminishes. Tables are given showing this behavior. *l*-Bornyl benzenesulfonate, m. 52°, $[\alpha]_{5461}^{17}$ –22.40° (C_6H_6 , *c* 2.5), –22.00° (EtOH, *c* 2.5) (yield 25%); the *d*-bornyl ester, m. 52°, $[\alpha]_{5461}^{17}$ 21.30°; *l*-bornyl naphthalene- β -sulfonate, m. 76°, $[\alpha]_{5461}^{17.5}$ –16.50° (C_6H_6 , *c* 3), –16.00° (EtOH, *c* 2.5) (yield, 60%); the *d*-bornyl ester also m. 76° and has the same rotation (opposite in sign); *l*-bornyl naphthalene- α -sulfonate, m. 90°, $[\alpha]_{5461}^{17.5}$ –23.20° (C_6H_6 , *c* 2.5), –26.4° (EtOH, *c* 2.5); the *d*-bornyl ester could not be completely purified.

C. J. WEST

Action of substituted aromatic amines on camphoric anhydride. Bromo- and iodocamphoranilic acids and camphorobromo- and iodophenylimides. MAHAN SINGH, RAM SINGH AHUJA AND KISHEN LAL, Punjab Univ. *J. Chem. Soc.* 1928, 2410-4.—When a substituted PhNH_2 is condensed with camphoric anhydride, a camphoranilic acid and the corresponding imide are formed, the relative quantities depending upon the nature of the substituent R and its position in the amine; the following % yield of the imides are reported (the 3 values are for p , m and o , resp.): CO_2H , 0 for all 3; Me, trace of p ; Cl, 15-20, 6, 5; I, 25-30, 31, —; Br, 40, 25, 5-10. • The ratio acid/imide is also dependent upon the temp. at which the reaction is carried out, though the order in which the substituents affect the ratio is the same as that given above. All the condensations except that of $o\text{-IC}_6\text{H}_4\text{NH}_2$ were carried out at $145\text{--}50^\circ$ by heating 3-4 hrs. 4'-Bromocamphoranilic acid, m. $206\text{--}7^\circ$; camphoro- p -bromophenylimide, m. 182.5° . The condensation with $o\text{-IC}_6\text{H}_4\text{NH}_2$ was carried out at 115° , since at higher temps. a viscous oil was obtained and the yield of acid was seriously diminished. 2'-Iodocamphoranilic acid, m. $147\text{--}9^\circ$; 3'-I deriv., m. $226\text{--}7^\circ$; 4'-I deriv., m. 221° ; camphoro- m -iodophenylimide, m. 172° ; p -I deriv., m. 197° . The following values are reported for $[\text{M}]_D$ for camphoranilic acid and its 2'-substituted derivs. (the 4 values are for solns. in MeOH, EtOH, Me_2CO and MeEtCO): H, 150, 131, 101, —; CO_2H , —584, —574, —551, —390°; Me, 146, 144, 98, 90.75°; I, 50.9, —, —82.8, —70.17°; Br, 36, 21.9, —61.1, —31.96°; Cl, 57.8, 35.6, —40.3, —28.5°; OMe, 29.6, 27.6, —16.3, —9.55°. Values of $[\alpha]_D$ are also given for the 2'-Br and I, 3'-Br and I and 4'-Br and I derivs. of the acid and for the o -, m - and p -Br and the m - and p -I derivs. of the imide in the same 4 solvents. The p -isomer has in all cases the max. rotation; the o -Br and o -I acids give negative values in Me_2CO and MeEtCO . As regards their effect in diminishing the mol. rotatory power in Me_2CO and EtMeCO , the order of substituents is that of their effect on the optical activity of menthyl and *sec*- β -octyl esters of mono-substituted AcOH and BzOH; this also corresponds to the relative polarity of the groups as deduced from mol. inductive capacities. For MeOH and EtOH there is a small displacement in the order of the substituents.

Molecular configuration of polynuclear aromatic compounds. VIII. 6,6'-Dimethoxydiphenic acid. JAMES KENNER AND HAROLD A. TURNER. Univs. of Sheffield and Sydney. *J. Chem. Soc.* 1928, 2340-3.—2,3- $\text{H}_2\text{N}(\text{MeO})\text{C}_6\text{H}_3\text{CO}_2\text{H}$ is converted by the ordinary procedure into 2-iodo-3-methoxybenzoic acid, yellow, m. $150\text{--}1^\circ$; Me ester, m. 57° ; Cu at $205\text{--}10^\circ$ converts the latter into di-Me 6,6'-dimethoxydiphenate, m. $137\text{--}8^\circ$; hydrolysis gives the free acid, m. $288\text{--}90^\circ$ (decompn.). The brucine H salt m. 268° . The acid was resolved by quinine; quinine l -acid, the less sol. of the 2 salts, m. $172\text{--}3^\circ$, $[\alpha]_D -291^\circ$ (H_2O , c 0.59); the free l -acid, m. $294\text{--}5^\circ$, has $[\alpha]_D -115^\circ$ (Me_2CO , c 0.56). Quinine d -acid, obtained as an oil which could not be crystd.; $[\alpha]_D -68^\circ$ (CHCl_3 , c 1.27); the NH_4 in H_2O salt had $[\alpha]_D 254^\circ$. Complete sepn. could not be obtained by the use of quinidine.

A note on an attempt to prepare p -diphenylene. ANUKUL CHANDRA SIRCAR AND JNANENDRA NARAYAN MAJUMDAR. *J. Indian. Chem. Soc.* 5, 417-8(1928); cf. C. A. 21, 402.—In an attempt to prep. p -diphenylene by the action of Cu on p,p' -diiododiphenyl, tetraphenylene, $(\text{C}_6\text{H}_4)_4$, white plates from C_6H_6 , m. $304\text{--}5^\circ$ were obtained. When H_2O was present Ph_2 was obtained.

PAUL J. CULHANE

Nitration and bromination of 4-methylbenzophenone. WM. BLAKEY AND HAROLD A. SCARBOROUGH. Univ. of Cambridge. *J. Chem. Soc.* 1928, 2489-96.—4- $\text{MeC}_6\text{H}_4\text{Bz(I)}$, m. 56° ; HNO_3 (d. 1.5) gives the 3- NO_2 deriv.(II), pale yellow, m. 129° , also obtained from 4,3- $\text{Me}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{COCl}$ and C_6H_6 with AlCl_3 . Reduction of II with Sn and HCl gives the 3- NH_2 deriv.(III), m. 109° (HBr salt, m. 130° ; Ac deriv., m. 108°). The 3-Br deriv.(IV), m. 107° , results from I in dry Br after standing in the sunlight for 2 days, from III through the diazo compd. with CuBr and from 3,4-Br- $\text{MeC}_6\text{H}_3\text{COCl}$ and C_6H_6 with AlCl_3 . 3,3'-Di- NO_2 deriv., pale yellow, m. 135° , results from II in $\text{H}_2\text{SO}_4\text{-AcOH}$ and HNO_3 or from 4,3'- $\text{Me}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{Bz}$ and HNO_3 . 4,3,5- $\text{Me}(\text{O}_2\text{N})_3\text{C}_6\text{H}_2\text{COCl}$, C_6H_6 and AlCl_3 give the 3,5-di- NO_2 deriv., yellow, m. 109° ; reduction gives the 3- NH_2 deriv., deep orange, m. 157° . 3,3',5-Tri- NO_2 deriv., pale yellow, m. 173° , results by the action of an excess of HNO_3 upon any NO_2 deriv. 4,4'- $\text{Me}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{Bz}$ and excess of HNO_3 give the 3,4'-di- NO_2 deriv., m. 130° , reduced by H_2S and NH_4OH to the 4'- NH_2 deriv., yellow, m. 164° ; removal of the NH_2 deriv. gives III. 4,4'- $\text{Me}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{Bz}$, H_2SO_4 and HNO_3 give the 3,4',5-tri- NO_2 deriv., pale

yellow, m. 160°; this does not react with piperidine but $p\text{-ONC}_6\text{H}_4\text{NMe}_2$ gives a light brown amorphous powder; reduction gives the 4',5-di-NH₂ deriv., orange, m. 202°, which yields II on removal of the NH₂ groups. Further nitration of the tri-NO₂ deriv. by heating with H₂SO₄ and HNO₃ 6 hrs. on the H₂O bath gives the 3,3',4',5-tetra-NO₂ deriv., yellow, m. 187°; piperidine, HOH-NH₂, and MeONa each give a light brown amorphous product. 4,3'-Me(O₂N)₂C₆H₃Bz and excess dry Br give the 3-Br deriv., pale yellow, m. 124°; 3'-NH₂ deriv., yellow, m. 94°; deamination gives IV. 3,5-(O₂N)₂C₆H₃COCl and PhMe with AlCl₃ give 3',5'-dinitro-4-methylbenzophenone, pale yellow, m. 134°, whose 3-Br deriv., pale yellow, m. 173°. 3-Bromo-4'-nitro-4-methylbenzophenone, pale yellow, m. 119°; 4'-NH₂ deriv., pale yellow, m. 162°, and on deamination yields IV. 4'-Chloro-3-nitro-4-methylbenzophenone, m. 98°, from $p\text{-ClC}_6\text{H}_4\text{COCl}$, PhMe and AlCl₃, followed by nitration, or 4,4',3-Me(H₂N)(O₂N)₂C₆H₃Bz through the diazo reaction; reduction gives the 3-NH₂ deriv., pale yellow, m. 142°. 4,3-Cl-(O₂N)₂C₆H₃COCl and PhMe give 4'-chloro-3'-nitro-4-methylbenzophenone, yellow, m. 121°; HNO₃ gives the 3,3'-di-NO₂ deriv., yellow, m. 181°. 4'-Chloro-3,5-dinitro-4-methylbenzophenone, yellow, m. 118°; the 3,3',5-tri-NO₂ deriv., yellow, m. 182°. 4'-Chloro-3-bromo-4-methylbenzophenone, m. 122°. A comparison of the behavior of the Me and the MeO groups show that they are alike in that the sequence in which substituents enter is the same, with 1 exception, and the methods by which these substituents are introduced are similar. They differ in that on di- and tri-substitution the Me groups lead to only 1 isolable isomer, whereas with the MeO group at least 2 isomers are obtained.

C. J. WEST

Autoxidation of organic compounds. VI. Autoxidation of thiobenzophenone.

H. STAUDINGER AND H. FREUDENBERGER. *Ber.* 61B, 1836-9(1928); cf. *C. A.* 19, 2658.—In the description of a simple method of prepg. Ph₂CS (*C. A.* 22, 4510) it was stated that the autoxidation of Ph₂CS does not proceed according to the scheme $2\text{Ph}_2\text{CS} + 2\text{O}_2 \longrightarrow (2\text{Ph}_2\text{C.S.O.O}) \longrightarrow 2\text{Ph}_2\text{CO} + \text{SO}_2 + \text{S}$, but that only a little SO₂

is liberated and that along with Ph₂CO is formed a trisulfide, decomps. about 124°, which decomps. quant. into Ph₂CS and S. Only 1/8 mol. SO₂ is formed and there is an increase in wt. of about 3%. The Ph₂CS and O must therefore react primarily according to the scheme $2\text{Ph}_2\text{CS} + \text{O}_2 \longrightarrow (\text{Ph}_2\text{C.S.S.CPh}_2\text{O.O}) \longrightarrow 2\text{Ph}_2\text{CO} + 2\text{S}$,

and the nascent S yields in part the trisulfide, in part polymerizes to amorphous S and, in very small part, is autoxidized. The Ph₂CS autoxidation therefore proceeds according to the scheme $6\text{Ph}_2\text{CS} + \text{O}_2 \longrightarrow 2\text{Ph}_2\text{CO} + 2(\text{Ph}_2\text{C})_2\text{S}_3$, for which the calcd. increase in wt. is 2.69%. As a part of the S polymerizes the actual increase in wt. is somewhat greater and the yield of Ph₂CO greater, that of trisulfide smaller than the calcd., and this is the more pronounced the more rapid the autoxidation, *e. g.*, when very finely divided Ph₂CS autoxidizes. The best yields of trisulfide are therefore obtained when the autoxidation is effected very slowly in the cold. At 120°, at which temp. the trisulfide decomps., only Ph₂CO, crystd. S and very little SO₂ are formed. Ph₂CS and ordinary rhombic S₈ do not give the trisulfide in CS₂.

Acylation and alkylation of some compounds of the aromatic series in the presence of tin tetrachloride. G. I. STADNIKOV AND A. BARYSHEVA. *Tor.-Inst., Moscow. Ber.* 61B, 1996-9(1928).—The reaction of alkyl halides and aromatic chlorides with aromatic compds. in the presence of SnCl₄ is more or less peculiar and permits of making an interesting distinction between different classes of aromatic compds. and between C₆H₆ and thiophene (cf. *C. A.* 22, 3981). Thus, while C₆H₆ and its homologs react readily with PhCH₂Cl in the presence of SnCl₄, they do not react with acid chlorides, and BzOEt does not react with BzCl, AcCl or PhCH₂Cl. Thiophene and its homologs, on the other hand, react readily with AcCl. The behavior of cresol ethers is described in this paper. They react with acid chlorides with extraordinary ease, forming deeply colored complex compds. which with H₂O give the corresponding ketones in good yield. With PhCH₂Cl in boiling solvents (benzine, b. 80-100°) they give mono- and disubstituted phenol ethers. Thus, from 24.4 g. *o*-MeC₆H₄OMe and 15.6 g. AcCl allowed to stand overnight with 52 g. SnCl₄ is obtained 28 g. 5,2-Ac(MeO)₂C₆H₃Me, b₂₃ 171-2°, d₄²⁰ 1.0812, n_D²⁰ 1.5538; semicarbazone, m. 206-7°. The Bz analog, b₄₈ 240-54°, is obtained in 76% yield. 2,4-Me(MeO)₂C₆H₃COMe, similarly obtained in 84% yield from *m*-MeC₆H₄OMe, b₂₃ 163-4°, b₇₃ 267-8°; semicarbazone, m. 179-80°. 2-Methyl-4-methoxybenzophenone (73%), b₂₃ 219-21°, d₄²⁰ 1.1250, n_D²⁰ 1.6016. 3,4-Ac(MeO)₂C₆H₃Me (88%), b₂₃ 143-6°, d₄¹⁷ 1.0636, n_D¹⁷ 1.5375. 5-Methyl-2-methoxybenzophenone (77%), b₂₀ 210-1°, m. 37-8°. *m*-MeC₆H₄OMe (24.4 g.) with 25.3 g. PhCH₂Cl

and 52 g. SnCl_4 gives 40% of a *methylmethoxydiphenylmethane*, b_p 181–7°, and 10% of a *methylmethoxydibenzylbenzene*, m . 75–6° C. A. R.

Hydrogenation of fluorene under pressure in the presence of nickel or osmium with the addition of cerium and thorium. V. S. SADIKOV AND A. K. MICHAILOV. *Staats-Inst. angew. Chem., Leningrad. Ber.* 61B, 1792–6(1928).—Ipat'ev had found that the hydrogenation of fluorene (I) with Ni under pressure is very difficult; 20 g. I with 3 g. NiO must be heated 24 hrs. at about 300° under 120 atm. H_2 to give decahydrofluorene (II) and the latter must be heated again a long time with fresh or reactivated NiO to give perhydrofluorene (III). S. and M. have now found that when 40 g. I and 1.6 g. Os on 27.4 g. asbestos under 105 atm. H_2 (at 25°) is heated to 300° (the pressure rises to 165 atm.) hydrogenation is complete in 6.5 hrs., the pressure decreasing 105 atm. (77 atm. at room temp.), or 29, 25, 15, 13, 11 and 5 atm., resp., in each succeeding hr., and the product consists of about 78% II and 22% III. With 3.18 g. Os and 0.16 g. CeO_2 on 12.56 g. asbestos, the max. pressure attained at 300° is 153 atm., 0.5 of the H_2 is absorbed in the first 15 min. and reduction is practically complete in 4.5 hrs. (decrease in pressure each hr. 81, 15, 6, 5, 2, 2 atm.), giving about 93% III. With 26 g. I and 1.2 g. Os-asbestos in the presence of 1% ThO_2 the max. pressure is attained at 280° and decreases 48, 34, 17, 7, 8 and 6 atm., resp., in each succeeding hr., the product consisting of III exclusively. With 18 g. NiO-asbestos (14.25% Ni) and 113 atm. H_2 at 25° the pressure decreased at 300° from 193 atm. at the rate of 16, 8, 7, 6, 6, 8, 6 atm. per hr. and the product consisted of 24.15% unchanged I and 73.2% II. With 15 g. of the NiO-asbestos and 1% CeO_2 , the pressure decrease is 64, 13, 7, 4, 4, 6, 5, 4 atm. per hr. (40 atm. in the first 15 min.) and the product contains 98.2% III. With 30 g. I, 15 g. of the NiO-asbestos, 1% ThO_2 and 130 atm. H_2 at 20° the pressure increases to 256 atm. at 300° and decreases 0, 3, 4, 0, 2, 3, 2, 0, 0 atm. each succeeding hr.; all the I is recovered unchanged. Os is therefore a much more active catalyst for I than NiO, but in the presence of CeO_2 NiO is as effective as Os. C. A. R.

Catalytic hydrogenation processes: interrupted hydrogenation of quinoline under pressure in the presence of osmium and cerium. V. S. SADIKOV AND A. K. MICHAILOV. *Staats-Inst. angew. Chem., Leningrad. Ber.* 61B, 1797–1800(1928).—It was found in the work described in the preceding abstr. that the hydrogenation of cyclic compds. follows a wave-like course, which may be explained by periodically changing states of temporary stimulation and paralysis of the catalyst. To obtain as rapid and complete a hydrogenation as possible of a given substance, the following exptl. conditions must be controlled: (1) Definite optimum temp. of the substance to be hydrogenated; (2) suitable compn. and a corresponding state of the catalytic system; (3) certain mutual relations between the catalyst and the substance to be hydrogenated. An active catalytic mass can exert its hydrogenating power only when both the catalyst and the substance to be hydrogenated are within certain temp. limits (e. g., for quinoline and asbestos- OsO_2 - CeO_2 , about 340°). The following questions suggested themselves: (1) May not this permanently high temp. acting a long time injure the activity of the catalyst? (2) Is a permanent increase in the initial temp. really necessary to keep the catalyst active? (3) May not the catalyst, stimulated by the initial rise in temp., thereafter effect hydrogenation independently of the optimum temp. (e. g., at room temp.)? A series of expts. was therefore run in which quinoline was hydrogenated at the initial optimum temp. and another in which the temp. was repeatedly raised for short intervals to this point. An Ipat'ev autoclave, contg. 60 g. quinoline and 10 g. catalyst (asbestos with 20% OsO_2 and 1% CeO_2) under 100 atm. of H_2 , was placed in an elec. oven at 320–40°. The autoclave attained the oven temp. in 30–75 min. and the pressure rose to a max., remained const. for some min. and then began to fall; 20–50 min. after the max. pressure had been reached, the autoclave was removed from the oven and quickly cooled and the pressure again recorded after 24 hrs. at room temp. In a typical expt., the autoclave was filled at 15° under 102 atm., the pressure reached a max. (187 atm.) at 336° in 40 min., remained const. 3 min., fell 13 atm. in the next 17 min. (fall per min. 2, 3, 4, 1, 2, 1, 0, 0...) at 336° and another 17 atm. in the next 24 hrs. after cooling to 15°. Thus the catalyst which was paralyzed in 7 min. at the high temp. recovered its activity at room temp. and was able to effect hydrogenation outside the optimum temp. limits; this same catalyst was unable to hydrogenate quinoline before it had been subjected to a preliminary short heating at the definite initial temp. The results of 17 such interrupted hydrogenations indicate that in the hydrogenation of most cyclic compds. it is not necessary to maintain permanently the high optimum temps.; they merely start up the process, which then continues independently of the temp.; in fact, long continuance of the high temp. may have an unfavorable influence on the activity of the catalyst. C. A. R.

Hydrogenation products of quinoline under pressure in the presence of osmium and cerium. V. S. SADIKOV AND A. K. MICHAJLOV. Staats-Inst. angew. Chem., Lenin-grad. Ber. 61B, 1801-6(1928).—The object of this investigation was the elucidation of the nature of the by-products formed in the hydrogenation of quinoline (cf. C. A. 22, 1924). From the fractions boiling above 250° was isolated a thick, light yellow, oily base, $C_{15}H_{26}N_2$, of peculiar odor, b_{15} 275–90°, forms no picrate, changed to orange-red by HCl, yielding the brick-red *di-HCl salt*, from which can be obtained a H_2O -sol. ferrocyanide. The base forms a MeI addn. product and is probably 7-methyl-bis-1,2,3,4,7,8-hexahydro-1,1'-quinolyl. The 165–200° products obtained in the hydrogenation of quinoline with 20% CeO_2 + 1% OsO_2 yielded fractions b_{15} 70–85°, d_{15} 0.8705, and b_{15} 85–90°, d_{15} 0.8814, which gave a salt $C_{17}H_{26}N_2 \cdot 2HCl$, m. 276°; the base is probably a 1-[2'-methyl-3'-ethyl-1'-piperidino]-1,2,3,4,5,6,7,8-octahydroquinoline. Interrupted hydrogenation of quinoline (see preceding abstr.) with 20% OsO_2 + 1% CeO_2 gave the following fractions: 75–100°, 5.0%; 100–50°, 11.8%; 150–75°, 17.7%; 175–90°, 27.5%; 190–200°, 7.5%; above 200°, 30.0%. The 150–75° fraction gave the salts $C_{16}H_{26}N_2 \cdot HCl$, m. 226°, and $C_{17}H_{27}N \cdot HCl$, m. 156°; the bases are probably [3-methyldecahydro-2-quinolyl]amine and 2-methyl-3-ethylpiperidine, resp. From the 175–90° fraction were obtained a salt $C_{19}H_{38}N_2 \cdot 2HCl$, m. 172° (probably of 2-methyl-3-aminobisdecahydro-1,1'-quinolyl), a base $C_{14}H_{26}N_2$, possibly *N*-piperidinodecahydroquinoline, and a ferrocyanide which from its compn., $C_{14}H_{27}N \cdot H_4Fe(CN)_6$, may be a salt of 2,3-diethyl-1-methyldecahydroquinoline. If the 175–90° and 190–200° fractions are treated in alc. with CO_2 or are distd. in CO_2 they yield solid compds., $C_{18}H_{38}N_2O_2$ and $C_{27}H_{46}N_2O_2$, resp., which form no picrates nor ferrocyanides and evolve CO_2 with acids; the 2nd probably has the structure $\underline{CH_2 \cdot CH_2 \cdot CH(CH_2CH_2) \cdot CH(CH_2CH_2) \cdot NNMe}$.

$CH(CH_2CH_2)CH_2CH_2CH(CH_2CH_2)CH_2CH_2NHCO_2H$. The hydrogenation of quinoline is therefore quite a complex process and is accompanied by numerous side reactions which are strongly influenced by the nature of the catalyst and by the thermal conditions. The following stages in the hydrogenation have been established: (1) With CeO_2 tetrahydroquinoline is formed almost exclusively; (2) with Os there is a very greatly accelerated formation of the higher hydrogenation products, up to the decahydro deriv.; (3) at the same time is formed a relatively insignificant quantity of a condensation product of 2 hexahydroquinoline mols., accompanied by alkylation, which may be considered an indication of incipient decompn. of the hydrogenation products; (4) with both CeO_2 and OsO_2 are formed considerable quantities of products of the further transformation of the decahydroquinoline in 3 directions, viz., condensation or linking together of individual hydrogenated quinoline rings, rupture of individual rings with formation of piperidine derivs., and secondary syntheses with formation of alkyl derivs. and amines from the individual fragments of the decompd. hexahydroquinoline rings. The formation of these secondary condensation and decompn. products can be ascribed only to the high temp. and to avoid it the primary hydrogenation products must be at once removed from the influence of the high temp. by the use of an autoclave with a cooled side arm (cf. C. A. 22, 1336).

C. A. R.

Preparation of compounds of the type of malachite green and of phenolphthalein by means of the Grignard reaction. JOSEPH S. CHAMBERLAIN AND MALCOLM F. DULL. Mass. Agr. College. J. Am. Chem. Soc. 50, 3088–92(1928).—Details are given of the prepn. of $Me_2NC_6H_4MgBr$ and its reaction with $(Me_2NC_6H_4)_2CO$ to give Me violet. *p*- $BrC_6H_4CO_2H$ does not readily yield a Grignard reagent; the reaction with $(Me_2NC_6H_4)_2CO$ gives only traces of chrome green. Two mols. $PhMgBr$ and 1 mol. *o*- $BzC_6H_4CO_2H$ give phthalophenone.

C. J. WEST

Preparation of crystal violet from oxalyl chloride and dimethylaniline. I. YA. POSTOVSKII. Ann. Inst. Polytech. Oural 6, 347–50(1927); cf. C. A. 22, 957(1928).

G. B. KISTIAKOWSKY

Resolution of benzoïn. ISAAC V. HOPPER AND FORSYTH J. WILSON. Royal Tech. College, Glasgow. J. Chem. Soc. 1928, 2483–9.—Benzoïn and *dl*- $PhMeCHNHCONH_2$ in C_6H_5N give 3 of the 4 possible racemic modifications of benzoïn δ -[α -phenylethyl]-semicarbazone; the least sol. is the β -modification, m. 154°; then follows the α -modification, m. 174°, and finally the γ -modification, m. 187°; the yields from 8 g. benzoïn are 4, 3 and 0.4 g., resp. In EtOH there are obtained the α - and β -modifications. *d*-Benzoïn δ -[α -phenylethyl]semicarbazone, from the 2 active components, m. 181–2°, $[\alpha]_D^{14}$ –140.7° (EtOH, *c* 0.4274); the same product was obtained from *dl*-benzoïn and the active *d*-semicarbazide, using C_6H_5N as the solvent; the other 3 forms were oily and very sol.; hydrolysis gave the *d*-benzoïn, identical with the synthetic product. By

means of *l*-δ-[α-phenylethyl]semicarbazide-HCl, m. 183°, $[\alpha]_D^{12.2} -66.06^\circ$ (H₂O, *c* 3.027), there was obtained the corresponding *l*-deriv., m. 181–2°, $[\alpha]_D^{14} 140.9^\circ$ (EtOH, *c* 0.7808), which yields *l*-benzoin on hydrolysis. A by-product of the resolution is benzil di-*d*-δ-[α-phenylethyl]semicarbazone, m. 233°, $[\alpha]_D^{17} 178.2^\circ$ (AcOH, *c* 0.4320).

C. J. WEST

Dioximes. XLIX. A. VIANELLO. Reale Univ., Torino. *Gazz. chim. ital.* 58, 326–8(1928); cf. de Paolini and Imberti, *C. A.* 22, 2750.—Ph(C₂N₂O₂)NH₂, which is of interest in explaining the structure of peroxides of glyoximes, has not been prepd. because of inability to dehydrogenate α-PhC(:NOH)C(:NOH)NH₂ (I) (cf. *C. A.* 17, 2268). Since BzC(:NOH)C(:NOH)NH₂ has now been transformed by Br water into Bz(C₂N₂O₂)NH₂, it seemed possible to carry out a similar reaction with I. Br water (theoretical proportion) added to ice-cold I in 10% H₂SO₄, and the ppt. recrystd. several times from C₆H₆ (with the use of animal charcoal) yields the phenylamino-glyoxime peroxide, Ph(C₂N₂O₂)NH₂ (II), m. 142°. II heated at 100° with Sn and concd. HCl, made strongly alk. with NaOH, extd. with Et₂O and crystd. from water, yields Ph(C₂N₂O)NH₂ (cf. *C. A.* 17, 2268). Wieland has already described a phenylamino-glyoxime peroxide (cf. *Ann.* 328, 252(1903)) which m. 135–6°, and which may have been the same as II. II may have any one of 3 formulas: (1) PhC:N.O.N(:O):CNH₂;

(2) PhC:N(:O).O.N:CNH₂, or (3) PhC:N.O.O.N:CNH₂, of which the first 2 are

phenylaminoximes and the 3rd is a true peroxide. II cannot be hydrogenated to PhC(:NOH)C(:NOH)NH₂ by the method of Angeli (Zn and AcOH), nor can it be reduced by SnCl₂, so the choice of formula remains in doubt. Unlike I, β-PhC(:NOH)C(:NOH)NH₂ (III) (cf. *C. A.* 17, 3875) in dil. H₂SO₄ is decompd., with evolution of gases, by Br water. The yield of III can be increased almost to the theoretical, and by a simpler method, by agitating PhC(:NOH)C(:NOH)Cl (10 g.) in Et₂O with 6 *N* NH₄OH (30 cc.), sepg. the aq. layer and eliminating the solvent. Br water (theoretical quantity) added to α-*p*-MeC₆H₄C(:NOH)C(:NOH)NH₂ (IV) (cf. *C. A.* 18, 1491) in 10% H₂SO₄, and the ppt. recrystd. from PhMe, yields *p*-tolylaminoglyoxime peroxide, *p*-MeC₆H₄(C₂N₂O₂)NH₂, m. 178°. Treated with Sn and boiling concd. HCl, as above, it is transformed to *p*-tolylaminofurazan, *p*-MeC₆H₄(C₂N₂O)NH₂ (V), m. 142°. IV treated with cold Ac₂O yields on recrystn. from dil. EtOH the *di*-Ac deriv., *p*-MeC₆H₄C(:NOAc)C(:NOH)NHAc, m. 168°. Heated briefly with 20% NaOH it forms V, which establishes the constitution of the latter. With Br water the β-form of IV and BzC(:NOH)C(:NOH)NH₂ behave like III. Since treatment with Br water of HC(:NOH)C(:NOH)NH₂, H₂NC(:NOH)C(:NOH)NH₂ or MeC(:NOH)C(:NOH)NH₂, all of which have but 1 form (β), completely destroys the compd., it is concluded that only the α-forms of aminoglyoximes can be dehydrogenated by Br to the corresponding peroxides.

C. C. DAVIS

Ring tension and radical formation. II. GEORG WITTIG AND FREIHERR VON LUPIN. Marburg, Chem. Inst. *Ber.* 61B, 1627–34(1928); cf. *C. A.* 22, 3878.—The results reported in the 1st paper gave certain indications that ring tension may assist the dissociating tendency of a C.C. union. Thus, the intense color of the biradicals

Ph₂CC₆H₄(CH₂)₂C₆H₄CPh₂, would seem to show that the 2 free ends have not satd. each other within the mol. and mol.-wt. detns. show that intermol. neutralization of valence occurs to but a small extent, evidently because of the opposing ring tension. It seemed possible that certain biradicals might be prepd. which might be converted intramol. into rings with less tension. Attempts were accordingly made to synthesize 1,1,2,2-tetraphenylcyclobutene (I) and -cyclobutane (II). As the vinyl group is comparable, in its radical-forming properties, to aryl groups it was to be expected that I would show a strong tendency to dissociate, while the satd. II, standing at the limits of ability to dissociate, might show weak radical formation because of the ring tension. In trying to synthesize I all attempts to obtain (:CHCXPh)₂, by halogenation of (CH:CPh)₂ failed; Br did not react and Cl at once gave (CHClCPh₂)₂, which, when rubbed with MeOH, yielded 2,3-dichloro-1,1,4,4-tetraphenylbutane-1,4-diol di-Me ether (III). III under suitable conditions readily forms the hydrofuran IV; on fusion, it does not yield IV but, for the most part, the acyclic 2-chloro-1,1,4,4-tetraphenyl-1,3-butadiene (V). The (CH:CPh)₂ was next treated with Na-K under N, yielding the violet addn. compd. (:CHCKPh)₂ (VI), whose structure was established by conversion with alc. into (:CHCHPh)₂ and with CO₂ into (:CHCPhCO₂H)₂. The K in VI was removed with O, S, I, CH₃I, and (CMe₃Br)₂. In all cases the suspension was in-

stantly decolorized and $(\text{CH}:\text{CPh}_2)_2$ was obtained exclusively; no intermediate color, pointing to the primary formation of the diradical, was observed, even when the reaction was carried out at -100° with $(\text{CMe}_2\text{Br})_2$. The rapidity of the formation of the $(\text{CH}:\text{CPh}_2)_2$ is also shown by the fact that when the K is removed with O no trace of a cyclic peroxide is formed. The prepn. of $(\text{CH}_2\text{CPh}_2\text{Cl})_2$ for the synthesis of II was also found impossible; all attempts to make it by replacing, by the usual means, the HO groups in $(\text{CH}_2\text{CPh}_2\text{OH})_2$ by Cl resulted in the elimination of H_2O or HCl and the formation of $(\text{CH}:\text{CPh}_2)_2$. Again, when the compds. $(\text{Ph}_2\text{CNaCH}_2)_2$ (VII) and $((\text{PhC}_6\text{H}_4)_2\text{CNaCH}_2)_2$ (VIII), formed by addn. of Na to $\text{Ph}_2\text{C}:\text{CH}_2$ and $(\text{PhC}_6\text{H}_4)_2\text{C}:\text{CH}_2$, resp., are treated with I or $(\text{CMe}_2\text{Br})_2$, the metal is at once removed and there are formed, with astonishing smoothness, not the cyclobutanes but the original $\text{R}_2\text{C}:\text{CH}_2$. That these are not merely the original substances which have remained unaltered is shown by the fact that the VII and VIII with alc. always yield the homogeneous $(\text{R}_2\text{CHCH}_2)_2$. That the hydrocarbon residue freed of the metal has a radical-like character, however, is shown by the fact that VII with O gives a cyclic peroxide (IX) which liberates I from HI-AcOH . As the above results indicate that tetraaryl cyclobutanes of the type I and II are not capable of existence, W. and L. doubt the correctness of the structure X assigned by Langenbeck (*C. A.* 22, 2746) to his dimeric ketenes; their deep color, the sluggishness of the radical C atoms toward O and the lack of reactivity of the C:O groups toward ketone reagents are all readily explained by the structure XI. The $(\text{CH}:\text{CPh}_2)_2$, obtained from $(\text{CH}_2\text{CPh}_2\text{OH})_2$ in boiling HCl-AcOH , forms colorless crystals with bluish fluorescence, m. 201° ; rubbing with concd. H_2SO_4 increases the fluorescence and gives a pink soln. gradually changing through light green to dirty brown. III (3 g. from 8 g. $(\text{CH}:\text{CPh}_2)_2$ in CCl_4 suspension with Cl, m. 183° (decompn.), reduced by Na and AmOH to $(\text{CH}_2\text{CHPh}_2)_2$, m. $118-9.5^\circ$. V, faintly yellow, m. $246-7^\circ$. 2,2,5,5-Tetraphenyl-3,4-dichlorofuran tetrahydride (IV), from III in boiling AcOH with CrO_3 or from the tetraphenylfuran 2,5-dihydride in CCl_4 with Cl, m. $280-1^\circ$, reduced by Na and AmOH to $(\text{CH}_2\text{CHPh}_2)_2$, gives with excess of NaOAm in AmOH the 3-chloro 2,5-dihydride, m. $168-9^\circ$. 1,1,4,4-Tetraphenyl-2-butene, m. $132-3^\circ$. 1,1,4,4-Tetraphenylbutene-1,4-dicarboxylic acid, m. $260-1^\circ$. 3,3,6,6-Tetraphenyl-1,2-dioxane (IX), m. $171-80^\circ$, forms in Et_2O (under N) a green soln. *asym-Dibiphenylethylene*, from $(\text{PhC}_6\text{H}_4)_2\text{CO}$ and MeMgI and elimination of H_2O from the resulting alc. by boiling in AcOH, m. $204-5.5^\circ$. 1,1,4,4-Tetraphenylbutane, m. $234-5^\circ$, mol. wt. in camphor 609.

C. A. R.

Constitution of the active principle of chita. I. AMARESH CHANDRA RAY AND SIKHIBHUSHAN DUTT. *J. Indian Chem. Soc.* 5, 419-24 (1928).—*Plumbagin* is the active principle of chitraka or chita, the root of *Plumbago rosea*, *P. zeylanica* and *P. europaea*. By extg. the roots with petr. ether, b. $70-90^\circ$, and several recrystns. from dil. EtOH , plumbagin is obtained in golden yellow needles, m. $77-8^\circ$, mol. wt. in freezing C_6H_6 296, sol. in Et_2O , CHCl_3 , Me_2CO , C_6H_6 , AcOH, insol. in cold H_2O , volatile in steam gives a blood-red color with FeCl_3 , a dirty-green ppt. with alc. $\text{Cu}(\text{OAc})_2$, no ppt. with AgNO_3 , $\text{Pb}(\text{OAc})_2$ or CaCl_2 ; *mono-Ac deriv.* m. 138° ; *mono-Bz deriv.* m. 147° ; *mono-carbethoxy deriv.*, m. 109° ; *dioxime*, m. 220° ; *monophenylhydrazone*, m. 198° ; *monosemicarbazone*, m. above 280° . Alk. KMnO_4 soln. gave *cinnamic acid* and traces of HCO_2H . Fuming HNO_3 gave a *tetranitro deriv.* Br gave a *dibromide*. Distn. with Zn dust gave a solid and a liquid smelling of C_{10}H_8 . From the liquid the picrate of *methyl-naphthalene* was obtained.

PAUL J. CULHANE

Nitroid and quinoid secondary valence combination. EDUARD HERTEL AND HEINZ KURTH. *Univ. Bonn. Ber.* 61B, 1650-3 (1928).—Two NO_2 groups in different C_6H_4 nuclei do not form a common field of residual affinity, since attempts to prep. mol. compds. of aromatic hydrocarbons with the following di- NO_2 compds. were unsuccessful: 1,8- and 1,5- $\text{C}_{10}\text{H}_8(\text{NO}_2)_2$, $(m\text{-O}_2\text{NC}_6\text{H}_4)_2\text{CH}_2$, 2,7-dinitrofluorene. The grouping *m*-nitro-carbonyl-*m*'-nitro likewise does not give rise to a common field of residual affinity since the following systems showed no evidence of compd. formation: $(m\text{-O}_2\text{NC}_6\text{H}_4)_2\text{CO-C}_{10}\text{H}_8$, 2,7-dinitrofluorenone-stilbene. H. and K. conclude that the mol. compds. formed by 2,7-dinitroanthraquinone are not due to a nitroid field of residual affinity but to a quinoid field. This is supported by the fact that although

anthraquinone does not form mol. compds. with aromatic hydrocarbons, 2,7-dichloro-, 1,2,3,5,6,7,8-heptachloro- and 1-nitroanthraquinone give deeply colored melts with $C_{10}H_8$, fluorene, acenaphthene and anthracene. The resolidified melts are colorless (cf. Pfeiffer, *C. A. B.* 1742; 11, 1410). The following systems form eutectics: anthraquinone-stilbene, 2,7-dichloroanthraquinone (I)-stilbene, I-hexamethylbenzene, I-anthracene, I- α -naphthol, heptachloroanthraquinone- β - $C_{10}H_7NH_2$. Although phenanthraquinone forms a compd. with hexamethylbenzene (Pfeiffer, *C. A.* 11, 1410), it does not form compds. with other hydrocarbons. Melts of 2,7-dibromophenanthraquinone with aromatic hydrocarbons are deeply colored but the resolidified melts are colorless. The following mol. compds. are described: 4,5-dinitrophenanthraquinone + acenaphthene (1:1), red, m. 165°; 2,7-dinitrophenanthraquinone (II) + acenaphthene (1:1), dark red, m. 255°; II + anthracene (1:2), dark violet, m. 250°; II + fluorene (1:2), red-yellow, m. 270°; 2,6,7-trinitrofluorene + stilbene (1:1), red, m. 148°. 2,3,6,7-Tetranitrofluorene gives deeply colored cryst. compds. with stilbene and anthracene.

DAVID DAVIDSON

Manufacture of β -naphthol. A. I. ZAKHAROV. *J. Chem. Ind. (Moscow)* 5, 720-1 (1928).—On melting dry neutral β - $C_{10}H_7SO_3Na$ contg. 4-8% mineral salts (chlorides and sulfates) at 295-300° with an excess of alkali (1-1.5 mols.), the fluctuations of the temp. of fusion are sharp. In the crude product obtained after decompn. with acids and washing, the β -naphthol content is usually not above 75-80% of the pure β -salt. It is generally thought that Na_2CO_3 , if added, interferes with the normal course of the fusion and contributes to resinification. In reality, if the fusion of the β -salt (contg. the same quantity of mineral salts) is effected under the same external conditions, but in presence of an excess of 1-2% Na_2CO_3 , the thermic bends of the fusion curve of the product are softened. The influence of Na_2CO_3 is even more noticeable in the external course of the fusion: the melt does not thicken, as it usually does in presence of ordinary salt in the course of addn. of the last portions of β -salt, and the phenomenon of local overheating and charring is completely absent. The reason is that, when the last portions of the sulfonate are added, the acid or even the neutral sulfonate tends to decomp. because of the decrease of total alkalinity in the kettle; the presence of Na_2CO_3 preserves the salt crystal from decompn. by the temp. at a moment when, for some reason, it did not yet have time to be influenced by $NaOH$. Thus the fusion runs fairly smoothly and without formation of decompn. products. The melt is lighter in color and preserves its liquidity even if fusions are effected with 0.5 mole excess of alkalinity. The β -naphthol content in the decompd. and washed melt is increased on the av. to 93-6%. A higher Na_2CO_3 content in the sulfonate has the inconvenience of causing the melt to froth, but this phenomenon does not harmfully affect either the quant. yield of β -naphthol or the total quantity of the melt. The frothing is observed toward the end of the fusion when the melt is usually heated to 310-5°.

BERNARD NELSON

Naphthylene 1,8-disulfide. WM. BENNETT PRICE AND SAMUEL SMILES. King's College, London. *J. Chem. Soc.* 1928, 2372-4.—The diazosulfonate from 1,8- $C_{10}H_6(NH_2)SO_3H$ in H_2O , satd. with SO_2 and treated with Cu powder, then satd. with $NaCl$ gives 1-sulfonaphthalene-8-sulfonic acid, isolated as the Na salt; reduction in H_2O with SO_2 and dil. HCl gives 1,1'-dithiodinaphthalene-8,8'-disulfonic acid, isolated as the Na salt; transformed into the chloride with PCl_5 and treated with Na_2SO_3 , this gives the corresponding disulfinic acid (I), m. 144°; reduction with Zn dust in EtOH-concd. HCl gives 1,8-dithiolnaphthalene (II), m. 113-4°, which could not be purified because of the ease with which it is transformed into naphthylene 1,8-disulfide, orange, m. 116°. Me_2SO_4 and II give 1,8-dimethyldithiolnaphthalene, m. 84°; $Ni(AcO)_2$ and II give a brownish purple Ni deriv., $C_{10}H_6S_2Ni$. Reduction of I with Zn dust and EtOH into which dry HCl is passed gives 2-phenylperinaphtha-1,3-dithiane, m. 116°.

C. J. WEST

Rubiadin. II. Synthesis of 2-methyl-1,3-dihydroxyanthraquinone. PRAFULLA CHANDRA MITTER AND PRIYALAL GUPTA. *J. Indian Chem. Soc.* 5, 25-8 (1928); cf. *C. A.* 22, 587, 2562.— p - $MeC_6H_4CO_2H$ mixed with P_2O_5 was sulfonated 3-4 hrs. at 210-20° and 1 hr. at 250° in a sealed tube (*Ber.* 20, 982 (1887)), cooled, poured on to ice and neutralized with $BaCO_3$. On boiling, addn. of K_2CO_3 , filtration and evapn. the K 2,6-disulfonate is obtained. This fused with KOH at 210-20°, rising slowly to 260°, gave 4,3,5- $Me(OH)_2C_6H_2COOH$ (I) and 2,1,4- $HOC_6H_3(COOH)_2$ (II). Isolate I by H_2O extn., acidifying, Et_2O extn., evapn. of Et_2O and extn. of the residue with small quantities of hot $PhMe$, m. 175-6°. From the residue from I isolate II by boiling with $PhMe$, then with $BaCO_3$ in H_2O and filter. The soln. of the Ba salt was acidified and extd. with Et_2O and the ext. dried and esterified with $MeOH$ and H_2SO_4 . Washed

with Na_2CO_3 and crystd. from MeOH . The di-Me ester of **II** was obtained, m. 93° (Burkhardt, *Ber.* 10, 146(1887), gives 94°). It was heated with 8 parts BzOH in H_2SO_4 at 120° for 15 hrs. and poured on to ice. Steamedistd. and recrystd. from C_6H_6 it gave 1,3-dihydroxy-2-methylantranthraquinone (**III**), m. 290° . Acetylation of **III** with Ac_2O ($\text{C}_6\text{H}_5\text{N}$ as catalyst) 6 hrs. and crystn. from EtOH gave the *Ac deriv.* (**IV**), m. 225° . By the large excess of BzOH the yield of **III** is better and formation of anthrachrysone almost prevented (cf. Schlunck and Marchlewski, *J. Chem. Soc.* 63, 969(1893)). **III** and **IV** correspond in properties with rubiadin and acetylrubiadin. •FOSTER DEE SNELL

Constitution and synthesis of rubicene. W. SCHLENK AND MARGARETE KARPLUS. Univ. Berlin. *Ber.* 61B, 1675-80(1928).—In the course of a study of the behavior of aromatic ketones towards CaH_2 was discovered a simple method of synthesizing rubicene (**I**) which has proved to be an anthracene deriv.

The synthesis is based on the observation that Ph_2CO and *p*- $\text{PhC}_6\text{H}_4\text{COPh}$ heated with CaH_2 condense intermol. to 9,10-diarylanthracenes, giving 9,10-diphenyl- (**II**) and 9,10-dibiphenylylanthracene (**III**), resp. Possibly the Ph_2CO adds CaH_2 in the heat as it does an alkali metal in the cold, the $(\text{Ph}_2\text{CHO})_2\text{Ca}$ thus formed loses $\text{Ca}(\text{OH})_2$ and the resulting dihydrodiphenylanthracene stabilizes itself to **II** with elimination of H_2 . Fluorenone in the same way gives **I**, the identity of which was established not only by its compn. and appearance but also by the characteristic color change through green to violet-black when the PhNO_2 soln. is heated with anhyd. AlCl_3 . The condensation reaction is apparently not applicable to all diaryl ketones; with neither Michler's ketone nor *p*- $\text{MeOC}_6\text{H}_4\text{CO}$ could an anthracene deriv. be isolated. With MeCOPh CaH_2 behaves differently, producing, like HCl , *sym*- $\text{C}_6\text{H}_5\text{Ph}_3$; at the same time is formed a *compd.* $\text{C}_{24}\text{H}_{20}\text{O}$, m. $165\text{--}6.5^\circ$, which, it was thought, might be an intermediate product between the MeCOPh and $\text{C}_6\text{H}_5\text{Ph}_3$ but all efforts to convert it into the latter have failed. **III**, yellow, m. considerably above 300° , is strikingly fluorescent in soln., minimal traces imparting to solvents a magnificent fluorescence (blue to red); its structure was established by its prepn., with boiling HCO_2H , from 9,10-dibiphenylyl-9,10-dihydroxydihydroanthracene (**IV**), m. 290° , gives a dark olive-green color with concd. H_2SO_4 ; the **IV**, in turn, was made from anthraquinone and *p*- $\text{PhC}_6\text{H}_4\text{MgI}$. C. A. R.

Chemistry of aromadendrene. I. LINDSAY H. BRIGGS AND WALLACE F. SHORT. Univ. College, Auckland. *J. Chem. Soc.* 1928, 2524-9.—The sesquiterpene fraction of the oil of *Eucalyptus nova-angelica*, after repeatedly fractionating in a vacuum over Na-K , finally was collected in 2 main fractions (representing about 20% of the original oil), which had the following properties: b_{10} 121° , $[\alpha]_{577}^{20} -6.1^\circ$, d_4^{20} 0.9116, n_D^{20} 1.4978; b_{10} $121\text{--}1.4^\circ$, $[\alpha]_{577}^{20} \approx 0^\circ$, d_4^{17} 0.9157, n_D^{17} 1.4993. These values indicate that the bulk of the sesquiterpene fraction consists of a single tricyclic sesquiterpene (aromadendrene (**I**)) exhibiting an exaltation of approx. 1 unit in its mol. refractive power. Exhaustive hydrogenation by the methods of Skita and Paal gives the *dihydro deriv.*, b_{10} $121\text{--}2^\circ$, d_4^{17} 0.9014, n_D^{17} 1.4871. Attempts to prep. solid addn. products from **I** have not been successful; the HCl deriv. cannot be distd. in a vacuum without considerable decompn. Dehydrogenation of **I** with S yielded a deep blue oil (b_{10} $122\text{--}65^\circ$), from which no C_{10}H_8 deriv. could be isolated, although a small quantity of a black picrate (azulene picrate?) was isolated from it. **I** and O_3 in AcOH give 61% of *aromadendrone* (**II**), m. $80\text{--}1^\circ$; *oxime*, m. 103° ; *semicarbazone*, m. $189.5\text{--}90.5^\circ$ (decompn.); dehydration of the oxime does not yield a nitrile. **II**, boiled with Ac_2O and AcONa , does not give an enol-acetate, indicating that the CO group is either situated in a side chain or attached to 2 quaternary C atoms in the nucleus. The result of the action of O_3 clearly shows the presence of the group $\text{CC}(\text{:CH}_2)\text{C}$. C. J. WEST

• The constitution of diprene. OSSIAN ASCHAN AND ILMARI KROHN. *Finska*

Kemistsamfundets Medd. 34, 68–71 (1925).—Diprene formed in isoprene on standing 10 yrs. at room temp., in a sealed glass container. The m. ps. of the di-HCl and the di-HBr salts of diprene are 51.5–52° and 46–7°, of which the 1st is identical and the 2nd almost with the m. ps. of the corresponding derivs. of carvestrene prep'd. by Baeyer (*Ber.* 27, 3485(1894)). The relation of diprene and carvestrene was established by the synthesis of the latter and conversion to the di-HBr salt which gave identical m. ps. This shows that diprene contains a *m*-cymene ring, but does not establish complete identity of carvestrene and diprene, since they may not have the same position for the double bond.

HANS C. DUUS

Synthesis of 1-phenanthrol. JOHN B. SHOESMITH AND ALEXANDER GUTHRIE. Edinburgh Univ. *J. Chem. Soc.* 1928, 2332–4. — α -C₁₀H₇CHO (*p*-nitrophenylhydrazone, scarlet, m. 233–5°), succinic anhydride and AcONa, heated 6 hrs. at 122°, give α -naphthylparaconic acid, m. 169°, which, heated at 180–200° for 30 min., loses CO₂ and gives 5% of 1-phenanthrol, m. 156°; this is stable in air, in contrast to the 9-isomer, which is very unstable; warming with CHCl₃ in alk. soln. gives a deep blue color; concd. H₂SO₄ gives a yellow soln., slowly becoming red and then colorless on heating; picrate, orange-red, m. 182°; the Me ether, m. 105°.

C. J. WEST

Improved method of preparing selenophene. HENRY V. A. BRISCOE, JOHN B. PEEL AND PERCY L. ROBINSON. *J. Chem. Soc.* 1928, 2628–9; cf. *C. A.* 22, 3657.—Se, in portions of 5 g., is heated in an inclined Pyrex tube, closed at the lower end and provided with an axial inlet tube delivering C₂H₂ some in. above the Se and well below a side tube leading to a condenser; the middle of the tube is heated to redness and the Se is slowly vaporized by heating it from the surface downward; a liquid condensate is formed at the rate of 3–4 cc. in 4 hrs. The reaction proceeds more smoothly if the Se is mixed with the C residue from previous runs. From 135 cc. of such a distillate there were obtained 20 cc. C₆H₆, 80 cc. selenophene, 10 cc. liquid hydrocarbon, b. 110–20°, and 10 cc. b. 150–80°, 10 g. C₁₀H₈ and 4 cc. of a green liquid contg. Se.

C. J. WEST

Conditions of formation of rings attached to the *o*-, *m*- and *p*- positions of the benzene nucleus. III. ALAN F. TITLEY. Dyson Perrins Lab., Oxford. *J. Chem. Soc.* 1928, 2571–83; cf. *C. A.* 20, 1794.—Et *o*-carboxyphenylpropionate, b₁₄ 182–3°, gives with Na in PhMe at 100° the Na deriv. of Et 1-hydrindone-2-carboxylate; the latter with PhNHNH₂.HCl and a little concd. HCl, heated on the H₂O bath and then 2 min. at 150°, gives 2,3-indeno(1,2)-indole, brownish red, m. 251°. Hydrolysis of Et 2-methyl-1-hydrindone-2-carboxylate, b₁₄ 156°, m. 31°, with 20% MeOH-KOH gives 60% of 2-methyl-1-hydrindone and 40% of β -*o*-carboxyphenylisobutyric acid, m. 141°. Et γ -*o*-carbethoxyphenylbutyrate, b₁₄ 188–9°, with Na in PhMe gives after 6–7 hrs. at 100° Et 1-keto-1,2,3,4-tetrahydronaphthalene-2-carboxylate (I), b₁₄ 183°, m. 33°; with PhNHNH₂.HCl and HCl I gives 1,2-indole(2,3)-3,4-dihydronaphthalene, dark red, m. 161°. I, Na and MeI give the 2-Me deriv., b₁₈ 183–4°; steam distn. with 20% H₂SO₄ gives 1-keto-2-methyltetrahydronaphthalene, b₂₀ 143°, while alk. hydrolysis with 10% MeOH-KOH gives a mixt. of the ketone and γ -*o*-carboxyphenyl- α -methylbutyric acid, m. 173°. The decrease in stability of the satd. ring on the addn. of the Me group is very strikingly exemplified in this instance, since the unmethylated ester is hydrolyzed to *o*-HO₂CC₆H₄(CH₂)₃CO₂H only by Na and boiling cyclohexanol and then to an extent of not more than 20%. Et *o*-phenylenedipropionate, b₁₂ 200–2°; 11.5 g. of the ester with 1.8 g. Na and 75 g. PhMe give 9 g. of the free acid and about 0.5 g. of a brown oil, b₁₈ 190°, which could not be purified but yields a phenylhydrazone, straw-yellow, m. 198° (decompn.), probably derived from Et 3-ketophenheptamethylene-2-carboxylate. Me *m*-phenylenediacetate (II), b₁₆ 185–7°; Et ester (III), b₁₈ 188–9°; Me *p*-phenylenediacetate (IV), b₁₈ 189–90°; Et ester (V), m. 59°. III and Na in PhMe give the free acid and a solid, sticky mass, softens and m. 30–40° and decomps. above 100°; attempts at distn. under 0.3 mm. led to complete decompn. with the formation of a horny, shellac-like mass. EtOH solns. give a deep purple color with FeCl₃ and a deep green Cu salt but no cryst. compd. is formed with PhNHNH₂; hydrolysis with EtOH-KOH gives yellow insol. resins. V gives almost precisely similar results but the sirupy mass yields an amorphous, red, glassy mass with PhNHNH₂, from which was obtained a small quantity of yellow needles, C₁₈H₁₈O₂N₂, m. 194–5°. II and Na in PhMe give 3 fractions, b₁ 131–5° (the free acid and phenylene-1-acetic-3- α -propionic acid, m. 132°); b₁ 217–22°, contg. the compd. C₂₄H₂₄O₆, with a bridged-ring structure and yielding on hydrolysis a lactone or acid anhydride, C₂₂H₁₈O₆, m. 345–6°; and b₂ 270° and upwards, contg. highly complex compds. IV behaves similarly and gave phenylene-1-acetic-4- α -propionic acid, m. 189°, and the compd. C₂₄H₂₄O₆, b₁ 225–8° *m*-Carboxyphenylpropionic acid, m. 177°; Me ester (VI), b₁₈ 184–5°. The *p*-isomer (VII

was synthesized in 2 ways: $p\text{-MeC}_6\text{H}_4\text{COCl}$ and Br give a mixt. of $p\text{-BrCH}_2\text{COCl}$ and $\omega\text{-bromo-}p\text{-toluyl bromide}$, b_{10} 170–1°, m. 58°, and also a high boiling product which yields with EtOH $\text{Et } \omega\text{-bromo-}p\text{-toluate}$, m. 103°. $\text{Et } \omega\text{-bromo-}p\text{-toluate}$, b_{10} 165°, m. 35–6°; with $\text{ClCH}(\text{CO}_2\text{Et})_2$ the results a fair yield of $\text{Et chloro-}p\text{-carbethoxybenzylmalonate}$, b_{10} 235°, m. 54–5°; reduction with Zn and AcOH gives $\text{Et } p\text{-carbethoxybenzylmalonate}$, b_{10} 218–9°, hydrolyzed to $p\text{-carboxybenzylmalonic acid}$, m. 186–8°; heating the latter to 240° gives VII, m. 294°. $p\text{-HO}_2\text{CC}_6\text{H}_4\text{CH}_2\text{CH:CHCO}_2\text{H}$ (Et ester , m. 52°), on reduction with Na-Hg and Na_2CO_3 , gives VII (Me ester , m. 33°). VI with Na and PhMe gives a product b_{10} 183–7°, which, on hydrolysis, yields the free acid and $\beta\text{-}m\text{-carboxyphenylisobutyric acid}$ (VIII), m. 137–8° (cor.), the constitution being established by the following synthesis: $m\text{-MeC}_6\text{H}_4\text{COCl}$ and 1 atom Cl give 90% of $\omega\text{-chloro-}m\text{-toluyl chloride}$, b_{10} 149–50°; EtOH gives $\text{Et } \omega\text{-chloro-}m\text{-toluate}$, b_{10} 168–9°; $\text{CHMe}(\text{CO}_2\text{Et})_2$ gives $\text{Et } m\text{-carbethoxybenzylmethylmalonate}$, b_{10} 234°; the free acid, m. 182–3° (decompn.), on heating at 185° gives VIII (Me ester , b_{10} 182°). $\text{Et } m\text{-phenylenedipropionate}$, b_{10} 197–8°; $p\text{-isomer}$, m. 69°. These reacted very slowly with Na , with the gradual formation of the Na salt of the acid. C. J. WEST

Stereoisomerism in polycyclic systems. V. WM. HENRY PARKIN, JR., AND SYDNEY G. P. PLANT. Dyson Perrins Lab., Oxford. *J. Chem. Soc.* 1928, 2583–90; cf. C. A. 22, 1978.—Suberone phenylhydrazone (18 g.), 360 cc. H_2O and 36 cc. concd. H_2SO_4 , heated on the H_2O bath for 25 min., give 11 g. 2,3,4,5-tetrahydroheptindole (I), m. 144° (*picrate*, dark crimson, m. 142°); reduction with Sn and HCl gives 2,3,4,5,11,12-hexahydroheptindole (II), m. 77°; *picrate*, yellow, m. 176° (decompn.); HCl salt, sparingly sol.; 10-Ac deriv., m. 87°; 10-Bz deriv., m. 116°; a 2nd isomer could not be isolated, and probably not more than 5% is formed. Suberone $p\text{-bromophenylhydrazone}$, m. 57°, quickly decomp. in the air; with H_2SO_4 , this gives the 7-Br deriv. of I, m. 129–30°; it is not basic; partial debromination occurs during attempted reduction. Reduction of 7,8,9,10-tetrahydroheptaquinoline gives the 5,7,8,9,10,11,14,15-octahydro deriv. (III), b_{24} 203°, isolated through the 5-Bz deriv., m. 145°; *picrate*, orange-red, m. 196°; no appreciable quantity of an isomer was formed. Suberone and $o\text{-H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$, heated 1 hr. at 120° and 15 min. at 210°, give 11-keto-5,7,8,9,10,11-hexahydroheptaquinoline, m. 344–5°; reduction with Na-Hg gives only III. A quant. study of the reduction of tetrahydroacridine with Sn and $\text{EtOH-H}_2\text{O-HCl}$ shows that octahydroacridine B and A are obtained in the ratio 17.3:4.7. Tetrahydroacridone is reduced by Sn and HCl to hexahydroacridone, yellow, m. 180°; *oxime*, pale yellow, m. 215–6°.

Metabolism of tryptophan. II. Synthesis of 6-methyl- and 8-methylkynurenic acid. WILLIAM ROBSON. King's College, Univ. London. *Biochem. J.* 22, 1157–64 (1928).—The starting points for 6-(I) and 8-methylkynurenic acid (II) were p - and o -toluidine, resp. p -Toluidine and $\text{AcCH}_2\text{CO}_2\text{Et}$ yielded p -methyl- γ -hydroxyquinaldine, MeC:CH.C.C(OH):CH (III) which gave the corresponding $\gamma\text{-Cl}$ compd. (IV)

and this reacted with NaOMe to form p -methyl- γ -methoxyquinaldine (V). Condensation of V with BzH gave benzylidene- p -methyl- γ -methoxyquinaldine (VI); with KMnO_4 in acetone, VI was converted to p -methyl- γ -methoxyquinoline-2-carboxylic acid (VII). HBr converted VII to p -methyl- γ -hydroxyquinoline-2-carboxylic acid (I). The synthesis of II followed along similar lines. III. The mode of formation of kynurenic acid from tryptophan. *Ibid* 1165–8.—In the formation of kynurenic acid from tryptophan, the pyrrole N of the latter compd. is eliminated and the side chain with its amino N forms the new pyridine ring.

BENJAMIN HARROW

Pure carbazole. T. V. ARISTOV. *J. Chem. Ind. (Moscow)* 5, 721 (1928).—Most manuals give 238° as the m. p. of carbazole; only 1 gives 247° on the basis of Kirby's work (cf. C. A. 14, 2936; 16, 1240). Kahlbaum's "pure" carbazole, m. 238–41°, was repeatedly recrystd. from several solvents (alc., glacial AcOH , C_6H_6 , PhMe , xylene, etc.). After the 1st recrystn. the m. p. rises to 239–42°; on further purification it reaches 246° and then remains unchanged. The purified substance appears in the form of brilliant fluorescent tablets which give the color reactions characteristic of

carbazole. *N detms.* Kahlbaum's carbazole 8.17%, purified carbazole 8.29%, theoretical 8.38%. The *picrate* obtained from purified carbazole m. 185.5°. It has been recommended to purify carbazole by H_2SO_4 , but A. advises against it, as it lowers the m. p. of the substance obtained after recrystn.; apparently partial sulfonation takes place.

BERNARD NELSON

Derivatives of tetrahydrocarbazole. VII. Reactions of 3-methyltetrahydrocarbazole, 6-chlorotetrahydrocarbazole and their acyl derivatives. SYDNEY G. P. PLANT AND REGINALD J. ROSSER. Univ. of Oxford. *J. Chem. Soc.* 1928, 2454-64; cf. C. A. 21, 91.—Crude 4-methylcyclohexanone (I) phenylhydrazone (7 g.) warmed with 120 cc. 17% H_2SO_4 for 15 min. gives 3-methyltetrahydrocarbazole (II), m. 109-10°. I *p*-nitrophenylhydrazone, yellow, m. 128.5°; with boiling 25% H_2SO_4 this gives the 6- NO_2 deriv. of II, brown, m. 165-6°. I *o*-nitrophenylhydrazone, crimson, m. 59°; this gives the 8- NO_2 deriv. of II, bright red, m. 188°. I *m*-nitrophenylhydrazone, orange-red, m. 80-1°; 27% H_2SO_4 gives a mixt. of the 5(or 7)- NO_2 deriv. (III) of II, yellow, m. 188°, and the more sol. 7(or 5)- NO_2 deriv., orange-red, m. 175°, in about equal quantities. Nitration of II in concd. H_2SO_4 at -10° with KNO_3 gives the 6- NO_2 deriv. II, boiled with 2.5 parts Ac_2O for 3 hrs., gives the 9-*Ac* deriv. (IV), m. 108.5°. Nitration with HNO_3 (d. 1.42) gives the 5(or 7)- NO_2 deriv., yellow, m. 134°, hydrolyzed to III. When IV was treated with HNO_3 (d. 1.42) at 50° and the NO_2 deriv. filtered off, the filtrate, on neutralizing with NaOH, gives the 10,11-di-*HO* deriv. of IV, m. 189-90°, which, boiled with Ac_2O for 2 hrs., yields 6-acetyl-3-methyl- ψ -indoxylspirocyclopentane, m. 93.5°. II, treated with $EtMgI$ and then with $BzCl$, gives the 9-*Bz* deriv., b₁₁ 255-65°, m. 99°; HNO_3 at 30° gives the 11,10-nitrohydroxy deriv., pale yellow, m. 123° (decompn.), while from the AcOH mother liquors there is isolated the 5(or 7)- NO_2 deriv., yellow, m. 142.5°, yielding III on hydrolysis. II, $EtMgI$ and $ClCO_2Et$ give *Et* 3-methyltetrahydrocarbazole-9-carboxylate, m. 66-7°; HNO_3 gives the 5(or 7)- NO_2 deriv., yellow, m. 104° and, from the AcOH mother liquor, the 10,11-di-*HO* deriv., m. 135°. Reduction of II with Sn and HCl gives a mixt. of 3-methylhexahydrocarbazole A (V), m. 58.5°, and a small quantity of the isomer B, m. 128°; electrolytic reduction gives only V. The 9-*Bz* deriv. of V m. 81.5°; the 9-*Ac* deriv., m. 101°; the *picrate*, yellow, m. 115-6°. Nitration of 6-chlorotetrahydrocarbazole (VI) in concd. H_2SO_4 at -10° with KNO_3 gives the 5(or 7)- NO_2 deriv. (VII), yellow, m. 183.5°. 4-Chloro-3-nitrophenylhydrazine, orange, m. 109°. Cyclohexanone 4-chloro-3-nitrophenylhydrazone, red, m. 106-7°; with boiling 25% H_2SO_4 there results a mixt. of VII and the 7(or 5)- NO_2 deriv. of VI, orange, m. 162°, in about equal quantities. 4-Chloro-2-nitrophenylhydrazine, red, m. 134°. Cyclohexanone 4-chloro-2-nitrophenylhydrazone, red, m. 101°. H_2SO_4 converts this into the 8- NO_2 deriv. of VI, orange-red, m. 213°. VI, on boiling with 4 parts Ac_2O 24 hrs., yields the 9-*Ac* deriv., m. 136°; nitration at 90° gives the 10,11-di-*HO* deriv., m. 222°; if the temp. is maintained at 80°, there is also obtained a small quantity of the 5(or 7)- NO_2 deriv., yellow, m. 184.5-5.5°, more easily obtained by treating the 9-*Ac* deriv. in AcOH at 55° with HNO_3 of d. 1.5; hydrolysis gives VII. The 9-*Bz* deriv. of VI, m. 122-3°, nitrated in AcOH at 80° with HNO_3 of d. 1.42, gives the 5(or 7)- NO_2 deriv., yellow, m. 148° and a small quantity of the 11,10-nitrohydroxy deriv., m. 147° (decompn.), more easily obtained with HNO_3 of d. 1.5 in AcOH at 40-50°. *Et* 6-chlorotetrahydrocarbazole-9-carboxylate, m. 111-2°; the 5(or 7)- NO_2 deriv., yellow, m. 126°. Fuming HNO_3 gives the 11,10-nitrohydroxy deriv., m. 136-7°; boiling EtOH transforms it into the 11,10-di-*HO* deriv., m. 132°.

C. J. WEST

Hetero-ring formations with thiocarbohydrazide. III. Reactions of substituted thiocarbohydrazides. PRAPHULLA CHANDRA GUHA AND SATYENDRA KUMAR ROY-CHOUDHURY. Univ. Dacca. *J. Indian Chem. Soc.* 5, 149-61(1928); cf. C. A. 20, 1810.—Aryl-substituted thiocarbohydrazides, $RR'NNHCSNHNH_2$ ($R = Ph$ or $Me-C_6H_4$, $R' = H$ or Me) have been prepd. by the action of $N_2H_4 \cdot H_2O$ on $RR'NNHCS_2Me$. The ring closure in the corresponding aldehyde thiocarbohydrazones, $RR'NNHCSNHN:CHR$, was effected with $FeCl_3$; for the resulting thiobiazoles the formula I is rejected because the thiobiazoles could not be hydrolyzed by boiling concd. HCl and no $RR'NNH_2$ could be detected in the soln. thus treated. Formula II thus appears to be correct. *o*- ClC_6H_4CHO with $PhNHNHCSNHNH_2$ (III) does not only yield a thiocarbohydrazone but the reaction proceeds a step further, with loss of HCl and formation of 2-phenylhydrazino-6,7-benzo-1,3,4-thioheptadiazine (IV), which cannot be desulfurized with HgO . With phenanthraquinone and acenaphthaquinone III gives 2,3-phenanthra- (V) and 2,3-acenaphtho-6-keto-1,4,5-oxdiazine phenylhydrazone (VI), the normal thiocarbazone first formed rearranging, by migration of a H atom, into the azo form (VII \rightarrow VIII), which changes, with loss of H_2S , into the oxdiazine.

With 1 mol. phenanthraquinone oxo-oxime **III** gives an oxheptatriazine (**IX**), with isatin a thiodiazine (**X**). With $\text{AcCH}_2\text{CO}_2\text{Et}$ **III** forms the thiocarbohydrazone (**XI**), which with NaOEt loses EtOH and yields 1-carbothiophenylhydrazido-3-methyl-5-pyrazolone (**XII**); with $\text{MeC(OH):CHCH}_2\text{Ac}$ is obtained 2-phenylhydrazino-5,8-dimethyl-1,3,4-thiooctadiazine (**XIII**), insol. in alkali and not desulfurized by HgO . The reaction of **III** with ω -Br ketones is analogous to that of thiosemicarbazides (Bose, C. A. 20, 415) except that it proceeds in only 1 direction (formation only of the thiodiazine), PhCOCH_2Br giving a compd. (**XIV**) which does not react with aldehydes. $\text{ClCH}_2\text{CO}_2\text{Et}$, on the other hand, gives a compd. (**XV**) contg. a $\text{NH}_2\text{N}=\text{}$ group, as it reacts readily with BzH . This difference can be explained by assuming that the C:O group of PhCOCH_2Br reacts with the hydrazino side of the **III** to form the thiocarbazone, which then yields **XIV** by loss of HBr , while with $\text{ClCH}_2\text{CO}_2\text{Et}$, HCl is eliminated first with formation of $\text{PhNHNHC(:NNH}_2\text{)SCH}_2\text{CO}_2\text{Et}$, which then loses EtOH to give **XV**. The PhNHNHCSNHN:CHR' with $\text{ClCH}_2\text{CO}_2\text{Et}$ or PhCOCH_2Br lose EtOH or H_2O , resp., forming thiodiazines (**XVI** or **XVII**), which on hydrolysis yield compds. reacting very readily with aldehydes and mustard oils and which must therefore contain a reactive $\text{NH}_2\text{N}=\text{}$ group. Phenylthiocarbohydrazone (**III**) (2.5 g. from 10 g. PhNHNHCSMe), m. $149-50^\circ$, sol. in alkalies, sparingly in HCl ; HCl salt, m. 181° , becomes light brown in the air. Et m-tolylthiocarbazinate (2 g. from 24 g. m- $\text{MeC}_6\text{H}_4\text{NHNH}_2$, EtBr and CS_2 with KOH in aq. alc.), m. 99° , sol. in alkali and reprecipitated by acids. m-Tolylthiocarbohydrazone, brownish white, m. $163-4^\circ$ (decompn.). Et 1-phenyl-1-methyldithiocarbazinate, oil; 1-methyl-1-phenylthiocarbohydrazone, m. $228-9^\circ$ (decompn.). 1-Phenylthiocarbohydrazones: benzaldehyde, m. 185° ; p-nitrobenzaldehyde, m. 192° ; cinnamic aldehyde, light yellow, m. $167-98^\circ$ (probably should be $167-68^\circ$ or $197-98^\circ$.—ABSTR.); salicylaldehyde, m. 206° (decompn.); acetone, m. 162° . p-Nitrobenzaldehyde 1-m-tolylthiocarbohydrazone, light yellow, m. $165-6^\circ$. 2-Phenyl-5-phenylhydrazino-1,3,4-thiodiazole (**II**, R and $\text{R}' = \text{Ph}$, $\text{R}'' = \text{H}$), orange, m. 172° , insol. in acids and alkalies. 2-Cinnamyl analog, dark red, shrinks 168° , m. 173° . 2-p-Nitrophenyl compd., golden yellow, m. $263-4^\circ$. **IV**, pale yellow, m. 195° . **VI**, reddish green, m. above 300° , insol. in acids and alkalies, gives a deep blue color with concd. H_2SO_4 ; m-tolylhydrazone, reddish green, m. above 295° . **VI**, black, m. above 300° . 3,4-Phenanthra-7-keto-1,2,5,6-heptaotriazine phenylhydrazone (**IX**), reddish green, m. above 300° . 2,3-Isatino-6-keto-1,4,5-thiodiazine phenylhydrazone (**X**), red, becomes brownish about 260° , brown at 300° . Et acetoacetate phenylthiocarbohydrazone (**XI**), m. $115-6^\circ$, sol. in alkali and reprecipitated by acids. **XII**, m. 142° (decompn.). **XIII**, m. 230° (decompn.). 2-Phenylhydrazino-5-phenyl-1,3,4-thiodiazine (**XIV**), m. 199° . 2,5-Diketo-4-phenyltetrahydro-1,3,4-thiodiazine hydrazone (**XV**), light brown, m. $152-3^\circ$, readily sol. in HCl ; benzal deriv., yellow, m. 158° . 2,5-Diketo-4-phenyltetrahydro-1,3,4-thiodiazine 2-salicylaldehydehydrazone (**XVI**), m. 220° , hydrolyzed by boiling, moderately concd. HCl to **XV**, which seps. as the HCl salt, m. $247-8^\circ$ (decompn.). Benzal analog of **XVI**, m. 189° (decompn.) (it is difficult to see why this compd. should be different from the benzal deriv. (above) of **XV**.—ABSTR.). 2-Keto-4,5-diphenyl-dihydro-1,3,4-thiodiazine salicylaldehydehydrazone (**XVII**), chocolate-colored, m. 221° .

C. A. R.

The constitution of compral. P. PREIFFER AND R. SEYDEL. Univ. Bonn. Z. physiol. Chem. 178, 81-96(1928).—On the basis of thawing point curves "compral" is a definite chem. compd. of 1 pyrimidone with 1 voluntal ($\text{CCl}_3\text{CH}_2\text{OCONH}_2$). Both components also have the property of forming similar compds. with other related substances. The following have been obtained in cryst. form: 1 sarcosine anhydride + 1 voluntal, m. 73° , 1 antipyrine + 1 phenylvoluntal, m. 70° , 1 sarcosine anhydride + 2 phenylvoluntal, m. 121° , 1 sarcosine anhydride + 2 urethan, m. 70° , 1 sarcosine anhydride + 2 phenylurethan, m. $95-7^\circ$. The following compds. were indicated by thawing point curves but could not be isolated: 1 acetylaminopantipyrine + 1 voluntal, and 1 antipyrine + 1 voluntal. The residual affinity of pyrimidone emanates from the acid amide grouping and not from the Me_2N group, since antipyrine itself shows this affinity. Substitution of 1 alkyl or aryl in the CONH_2 of voluntal weakens the

affinity and substitution of 1 alkyl and 1 aryl or 2 alkyls destroys it. The Cl atoms in voluntal contribute toward the affinity since neither urethan nor phenylurethan combines with pyrimidone, although both combine with sarcosine anhydride.

A. W. DOX

The constitution of hypnal and trigemih. P. PFEDER AND R. SEYDEL. Univ. Bonn. *Z. physiol. Chem.* **178**, 97-108(1928).—Hypnal (1 antipyrine + 1 chloral hydrate), bihypnal (1 antipyrine + 2 chloral hydrate), and trigemih (1 pyrimidone + 1 butylchloral hydrate) are definite mol. complexes as shown by thawing-point curves. Similar complexes now described are: 1 sarcosine anhydride + 1 chloral hydrate, m. 92-5°, crystd. from H₂O, and 1 sarcosine anhydride + 2 chloral hydrate, m. 83-86.5°, crystd. from C₆H₆. Neither cholesterol nor mannitol forms a compd. with CCl₃CH(OH)₂, MeCHClCCl₂CH(OH)₂ or sarcosine anhydride. To form such complexes an alc. must have 2 OH on the same C. The union between the 2 components is, however, unstable and a sepn. can usually be effected by means of a suitable solvent. This is not so with "anhydrohypnal," where an actual condensation between antipyrine and chloral has occurred with loss of H₂O.

A. W. DOX

More on α,β -benzisothiazolone. ARNOLD REISSERT. Univ. Marburg. *Ber.* **61B**, 1680-2(1928).—McClelland has called R.'s attention to the fact that he and his co-workers had already prepd. (*C. A.* **20**, 2327 and earlier papers) some of the compds. described by R. and Manns (*C. A.* **22**, 4114). Stollé obtained from HNO₂ and 3-aminobenzisothiazole a substance which should be 3-benzisothiazolone but its identity with R.'s and McC.'s compd. (I) has not been proved. R. has tried in vain (with HEINRICH DÜSTERDIEK) to prep. Stollé's benzisothiazole from I in 3 ways: (1) Zn dust distn. of I; (2) conversion of I with PCl₅ into 3-chlorothiazole (II), m. 40° and reduction of the II; and (3) reduction of I with HI. Distn. of I with Zn dust removes not only the O but also the ring S and PhCN is formed; II with Zn dust in boiling HCl gives the dimol. 3,3'-bisbenzisothiazolyl, m. 100°; reduction of I with fuming HI at 230° results in complete decompn.

C. A. R.

Formation of 2-substituted benzimidazoles. MONTAGUE A. PHILLIPS. May and Baker, Ltd., Wandsworth, Eng. *J. Chem. Soc.* **1928**, 2393-9; cf. *C. A.* **22**, 1356.—2-Methylbenzimidazoles are readily formed by the action of boiling dil. HCl on mono- or diacetyl-o-diamines and by the action of Ac₂O and HCl on o-C₆H₄(NH₂)₂; it has been suggested that the hydrolysis of the di-Ac to the mono-Ac compd. constituted a stage in the formation of the ring compd. from the former. The reaction has been extended and in view of its general nature it is now suggested that an alternative mechanism may be the hydrolysis of the diamine with subsequent ring formation. o-C₆H₄(NH₂)₂ (0.02 mol.), 0.03 mol. of the requisite acid and 20 cc. 4 N HCl were boiled 30-40 min. and the filtered soln. neutralized with NH₄OH; the following compds. were thus prepd.: HCO₂H, benzimidazole (I), 60% yield, m. 170°; AcOH, 2-Me deriv., 60%, m. 176°; EtCO₂H, 2-Et deriv., 70%, m. 177°; HOCH₂CO₂H, 2-hydroxymethyl deriv., 65%, m. 171-2°; MeCH(OH)CO₂H, 2- α -hydroxyethyl deriv., 70%, m. 178-9°; PhCH(OH)CO₂H, 2- α -hydroxybenzyl, 50%, m. 202-3°; BzOH, traces of 2-Ph deriv. I was also obtained by reduction of o-O₂NC₆H₄NHOCH and by the action of boiling 4 N HCl on o-H₂NC₆H₄NHOCH. 3-Nitro-4-lactaminophenetole, m. 115°, is reduced with Fe and dil. AcOH to the NH₂ compd., m. 135-6° (60% yield); 4 N HCl gives 5-ethoxy-2-[α -hydroxyethyl]benzimidazole, m. 170-1°. 3-Amino-4-formamidobenzyl cyanide, m. 124°, results in 50% yield by reducing the 3-NO₂ compd.; heating with HCO₂H for 20 min. gives 3,4-diformamidobenzyl cyanide, m. 92-5°; either deriv. with 4 N HCl gives 5-cyanomethylbenzimidazole, m. 158-9°. o-C₆H₄(NH₂)₂ and (CO₂H)₂ with 4 N HCl give 2,3-dihydroxyquinoxaline, does not m. 350° (Na salt, prisms). CH₂(CO₂H)₂ gives a mixt. of C₆H₄(NHCO)₂CH₂ (Na salt, cubes), and 2-aminomalonanilic acid, m. 175-6°; boiling with dil. HCl for 0.5 hr. gives C₆H₄(NHCO)₂CH₂. (CH₂CO₂H)₂ and o-C₆H₄(NH₂)₂ (1 mol. of each) give 2,2'-diaminosuccinanilide and benzimidazole-2-propionic acid; using 2 mols. o-C₆H₄(NH₂)₂ gives α,β -dibenzimidazolylethane and traces of the acid. That these reactions are not confined to the aromatic diamines is suggested by the ready conversion of C₂H₄(NHAc)₂ into 2-methyl-4,5-dihydroglyoxaline by boiling with dil. HCl.

C. J. WEST

Pseudo bases and their salts in the isoxazole series. II. E. P. KOHLER AND N. K. RICHTMYER. Harvard Univ. *J. Am. Chem. Soc.* **50**, 3092-106(1928); cf. *C. A.* **22**, 1973.—Triphenylisoxazole (25 g.) and 100 g. Et₂SO₄, heated at 120° for 5 hrs., the product digested with 50 cc. concd. HCl and 50 cc. H₂O on the H₂O bath for 1 hr., the cooled product extd. with Et₂O and then treated with excess of 1:1 aq. FeCl₃, give 42 g. of the FeCl₃ salt of the Et deriv. (I), pale yellow, m. 165-7°. I does not react with O₂, but KMnO₄ gives BzOH, a trace of AcOH and benzil. I and MeMgI give ethyl-1,2-

diphenyl-2-benzoylvinylamine, yellow, m. 118-9°, also obtained by the action of MeMgI upon $\text{PhBzC:C(N:CH}_3\text{)Ph}$; hydrolysis with MeOH-HCl gives $\text{Ph(BzO)}_2\text{CH}$ and $\text{Et-NH}_2\cdot\text{HCl}$. With NaOH I gives the pseudo base, *2-ethyl-3,4,5-triphenyl-5-hydroxyisoxazoline* (II), m. 120° (decompn.); the oxidation products are the same as I. II in Et_2O , shaken with an inadequate quantity of acid, gives an aq. soln. of the salt; by using HCl and FeCl_3 , I is regenerated; KBr and Br give a perbromide; KMnO_4 a violet permanganate, which ultimately decomps. Na added to II in Et_2O gives the lemon-yellow Na salt. II reacts with 3 mols. MeMgI and liberates 2 mols. CH_4 . With MeOH and NaOH there results the *Me ether* of II, m. 100°, decomps. 150°, giving IV. Treated with HCl, the chloride ppts. which reacts with NaCN to give *2-ethyl-3,4,5-triphenyl-5-cyanoisoxazoline* (III), m. 89°, losing HCN and giving IV. *Ethylidene- α,β -diphenyl- β -benzoylvinylamine* (IV), BzCPh:CPhN:CHMe , results from II by the loss of H_2O , from the Me ether by the loss of MeOH and from IV by the loss of HCN; because of the ease of hydrolysis it is difficult to obtain pure by any process; it is best prepd. by heating II at 120° and 3 mm. for 10 min., and finally crystg. from MeOH, when it m. 112°; boiling MeOH contg. a trace of alkali gives the *α -methoxyethyl deriv.*, $\text{BzCPh:CPhNHCH(OMe)Me}$, yellow, m. 140°. When a satd. Et_2O soln. of III is kept at room temp., there slowly deposits the *α -cyanoethyl deriv.*, pale yellow, m. 130°. Both of these derivs. decomp. above the m. p., giving IV. MeMgI and IV give the *iso-Pr deriv.*, yellow, m. 115°, whose structure was established by hydrolysis. Hydrolysis of IV gives *α,β -diphenyl- β -benzoylvinylamine*, bright yellow, m. 162°. In 1 expt., there was obtained an isomeric amine, $\text{C}_{21}\text{H}_{17}\text{ON}$, yellow, m. 208°. Synthetic expts. gave only the lower-melting amine. The mixt. of isoxazoles obtained by condensing nitrostilbene and *p*- $\text{BrC}_6\text{H}_4\text{CH}_2\text{NO}_2$, on ethylation and treatment with FeCl_3 , gives, on fractionation from EtBr, a salt, $\text{C}_{22}\text{H}_{16}\text{ONBrCl}_4\text{Fe}$, yellow needles from cold solns., brown plates from boiling solns., m. 172-4°. The yellow form slowly turns into the brown in contact with the mother liquor; on shaking with NaOH, there results *3,4-diphenyl-5-bromophenylisoxazole*, m. 172-3°. The product of ozonization is *β -benzilmonoxime-*p*-bromobenzoate*, $\text{C}_{21}\text{H}_{14}\text{O}_3\text{NBr}$, m. 145-6°, which is also obtained synthetically. The pseudo base, *2-ethyl-3,4-diphenyl-5-bromophenyl-5-hydroxyisoxazoline*, m. 105° (decompn.). The anhydro compd., *ethylidene- α,β -diphenyl- β -bromobenzoylvinylamine*, pale yellow, m. 102°; hydrolysis gives *α,β -diphenyl- β -bromobenzoylvinylamine*, deep yellow, m. 172°.

C. J. WEST

Methylene bases from 1-methylbenzothiazole and 1-methylbenzoselenazole methiodides; with a note on the preparation of 1-substituted benzothiazoles. L. E. S. LIE M. CLARK. Univ. College, Swansea. *J. Chem. Soc.* 1928, 2313-20.—1-Methylbenzothiazole-MeI (4 g.), suspended in Me_2CO and shaken with 50% NaOH, gives, among other products, 0.81 g. 2-methyl-1-methylenbenzothiazoline (I), m. 170°. *o*- $\text{HSC}_6\text{H}_4\text{NMeAc}$ (as the Na salt) and BzCl give the *Bz deriv.*, m. 87°. 1-Methylbenzothiazole methopicate, yellow, m. 94°; *II sulfate*, m. 177-8°; *methochloroplatinate*, deep yellow, m. 224° (decompn.); *perchlorate*, m. 149°. 1-Phenylbenzothiazole-MeI and AgOH give the Ag salt of *o*- $\text{HSC}_6\text{H}_4\text{NMeBz}$, whose *Bz deriv.*, m. 130-1°. 1-Phenylbenzothiazole methochloroplatinate, m. 243° (decompn.); *methopicate*, orange-yellow, m. 125-6°; *methoperchlorate*, m. 220°. The Zn salt of *o*- $\text{H}_2\text{NC}_6\text{H}_4\text{SeH}$ and AcCl in C_6H_6 give 1-methylbenzoselenazole, b₆₁ 140°; *chloroplatinate*, yellow needles; *methiodide* (II), m. 221° (decompn.); *ethiodide*, m. 212° (decompn.); *methochloroplatinate*, m. 214° (decompn.). The action of NaOH upon II gives 2-methyl-1-methylenebenzoselenazoline (III), pale yellow, m. 157-8°; the alk. soln., after removal of III is oxidized by $\text{K}_3\text{Fe(CN)}_6$ to 2,2'-diacetmethylamidodiphenyl diselenide, m. 141°. The methylene base formation is reversible, since heating I with EtOH-HCl gives 1-methylbenzothiazole, and III gives the corresponding Se compd. I and *p*- $\text{Me}_2\text{NC}_6\text{H}_4\text{CHO}$ heated in EtOH and then treated with HI give *p*-dimethylaminostyrylbenzothiazole-MeI, m. 244-5°. II and HC(OEt)_3 in $\text{C}_6\text{H}_6\text{N}$ give 2,2'-dimethylselenocarbocyanine iodide, bronze, m. 267-8° (decompn.); in EtOH, the absorption max. are at $\lambda 4500$ and $\lambda 6400$, while it confers sensitivity on a bathed plate up to $\lambda 7020$. The corresponding 2,2'-di-Et deriv., dark green, m. 270-1° (decompn.); the absorption max. in EtOH are at $\lambda 4500$ and $\lambda 6420$; the sensitivity band of a bathed plate has a slight max. at $\lambda 6200$, falling off steeply to the red at $\lambda 6940$. 2,2'-Diacetamidodiphenyl disulfide, m. 165-6°, is reduced to 1-methylbenzothiazole. The 2,2'-dipropionamidodiphenyl disulfide, m. 138°, is reduced to 1-ethylbenzothiazole, whose *picrate* m. 138°. 2,2'-Dibenzamidodiphenyl disulfide, pale yellow, m. 143-4.5°; reduction gives 1-phenylbenzothiazole.

C. J. WEST

Derivatives of 2-phenyl-6-methyl-4-pyrone. The non-resolution of 2-phenyl-6-methyl-4-pyrone *d*- α -bromocamphor- π -sulfonate. CHARLES S. GIBSON AND JOHN L.

Simonsen. Univ. of London. *J. Chem. Soc.* 1928, 2307-12; cf. Levy, Holmyard and Ruhemann, *C. A.* 9, 663.—The various views regarding the constitution of the 4-pyrone salts are discussed; the failure to resolve 2-phenyl-6-methyl-4-pyrone(I) would appear to support the coordination formulation. *I.HCl*, softens 105°, m. 165° (red oil); *perchlorate*, softens 135-7°, m. 145-7°; *sulfate*, m. 168-9°; *methylmethosulfate*, m. 140-3°, could not be purified by recrystn.; the 1st fraction sepg. from Me_2CO consists of a mixt. of the methylmethosulfate and the sulfate. *Methiodide*, decomps. 105°; this cannot be obtained directly from I and MeI; heated in a vacuum it decomps. into MeI and I; I also results by the action of Ag_2O or PbO ; HClO_4 gives the perchlorate, m. 145-7°. No indication of the resolution of *I d- α -bromocamphor- π -sulfonate* is obtained after 17 crystns.; the salt m. 157-8° [α]₅₄₁ 83.05°. I and piperonal in EtOH contg. a little KOH give 2-phenyl-6-piperonylidene-methyl-4-pyrone, m. 194°; concd. HCl gives a deep red soln., decompd. by the addn. of H_2O ; *perchlorate*, terra cotta, decomps. 143°; *d- α -bromocamphor- π -sulfonate*, orange, m. 205-6°; Br in CHCl_3 gives a bright red solid, which goes into soln. and then gives a yellow solid, m. 155-7°; on crystn. from Me_2CO , it apparently loses HBr and gives a mono-Br deriv., $\text{C}_{20}\text{H}_{19}\text{O}_4\text{Br}$, m. 222°.

C. J. WEST

Reactivity of atoms and groups in organic compounds. VII. The influence of certain solvents on reaction velocity—adjuvance. JAMES F. NORRIS and SPENCER W. PRENTISS. Mass. Inst. Tech. *J. Am. Chem. Soc.* 50, 3042-8(1928); cf. *C. A.* 22, 2378.—The results of the detn. of the velocity consts. of reactions in which an alc. serves simultaneously as a reactant and as a solvent cannot be correctly interpreted without a knowledge of the effect of the solvent on the rate at which the reaction takes place. *Adjuvance* is suggested as a convenient word to be used in expressing the property possessed by liquids of affecting the rate at which reactions proceed when the liquids are present as solvents. The velocity consts. of the reaction between $\text{C}_6\text{H}_5\text{N}$ and EtI in a no. of solvents have been detd.; the relative values of the consts. are as follows: C_6H_6 1, PhNO_2 25, Me_2CO 12.8, MeOH 2.5, EtOH 1.4, PrOH 1.11, BuOH 1.11, *iso-PrOH* 1.07, *sec-BuOH* 1.00, *tert-BuOH* 0.93. Values for d_4^{25} are given for the solvents.

C. J. WEST

A diphenylpyridylmethane dyestuff. E. PLÁZEK and E. SUCHARDA. Techn. Hochschule Lwów. *Ber.* 61B, 1811-3(1928).—In a continuation of the expts. on the prepn. of dyestuffs contg. a C_6H_5 instead of a C_6H_4 residue P. and S. attempted, but without success, to condense Michler's ketone with $\alpha\text{-C}_6\text{H}_4\text{NNH}_2$ with the aid of POCl_3 . Michler's hydrol, however, condenses with the $\text{C}_6\text{H}_4\text{NNH}_2$ in dil. H_2SO_4 , giving a tetramethyltriaminodiphenylpyridylmethane (I), which with PbO_2 or MnO_2 yields the corresponding dye (II) only at 120°. Attempts to prep. similar dyes from *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$ and $\text{C}_6\text{H}_4\text{NNH}_2$ with H_3AsO_4 or HgCl_2 failed. I, almost colorless, m. 163-5°, is distinctly basic, dissolves in mineral acids, seps. from C_6H_6 with 0.5 mol. solvent of crystn. II, which was not obtained pure and in very unsatisfactory yield, dyes wool directly from a neutral bath and tannated cotton a deep blue.

C. A. R.

2-Acetylaminopyridine. E. PLÁZEK and E. SUCHARDA. Techn. Hochschule Lwów. *Ber.* 61B, 1813-6(1928).—Chichibabin and his co-workers have found that nitration of 2- $\text{C}_6\text{H}_4\text{NNH}_2$ always gives the 5- and 3- NO_2 derivs., the former usually predominating largely. Needing large quantities of the 3- NO_2 compd. P. and S. attempted to nitrate 2- $\text{C}_6\text{H}_4\text{NNHAc}$ (I) in $\text{Ac}_2\text{O-AcOH}$ but found that no nitration takes place, the only product being I.HNO_3 which is exceedingly resistant to nitration, being unchanged by boiling fuming HNO_3 or $\text{HNO}_3\text{-Ac}_2\text{O}$. If it is treated with concd. H_2SO_4 , however, heat is evolved and 2,5- and 2,3- $\text{C}_6\text{H}_3\text{N}(\text{NH}_2)\text{NO}_2$ are formed in a violent reaction, but the nitration takes place only after the Ac group has been split off, for if the reaction is moderated by cooling, 2- $\text{C}_6\text{H}_4\text{NNHNO}_2$ can be detected as an intermediate product. With Br I behaves like PhNHAc , giving exclusively 2,5- $\text{C}_6\text{H}_3\text{N}(\text{NHAc})\text{Br}$ (II). 2-Acetylaminopyridine nitrate, m. 190°. 5-Bromo-2-acetylaminopyridine (II), m. 175°.

C. A. R.

A new method for the preparation of α,α' -dipyridyl. FR. HEIN and W. RETTER. Univ. Leipzig. *Ber.* 61B, 1790-1(1928).—The simplest conceivable way of prepg. α,α' -dipyridyl (I) is by the oxidation of $\text{C}_6\text{H}_5\text{N}$, and reasoning from the stability of the Fe^{II} complex $[\text{FeR}_3]\text{X}_2$ ($\text{R} = \text{I}$) that the tendency to the formation of this complex would under the proper conditions greatly facilitate any reaction whereby I can be prepd. H. and R. heated dry $\text{C}_6\text{H}_5\text{N}$ with anhyd. FeCl_3 , which ought to answer the double purpose of furnishing both the oxidizing agent and the Fe necessary for the formation of the complex. From 70 g. $\text{C}_6\text{H}_5\text{N}$ and 13 g. FeCl_3 heated about 35 hrs. around 300° they obtained 3.2 g. or 52% of practically pure I, m. 66-8° (apparently

the figure given for the quantity of C_6H_4N started with is a misprint.—ABSTR.). $FeCl_3 \cdot 6H_2O$ and anhyd. $CuCl_2$ (but not hydrated $CuCl_2$) can be used instead of anhyd. $FeCl_3$. C. A. R.

Deazahydroquinoline derivatives. IV. The Hofmann degradation of octahydro- α -methylindole. SHIN-ICHIRO FUJISE. *Sci. Papers Inst. Phys. Chem. Res. (Tokyo)* 9, 91-8(1928); cf. C. A. 22, 3663.— α -Methylindole was hydrogenated in AcOH at 40-50° in the presence of Pt black. Most of the AcOH was vacuum-distd., H_2O added and incompletely reduced material extd. with Et_2O . The soln. was then made strongly alk. and the base extd. with Et_2O . This ext. was dried with KOH, distd. and octahydro- α -methylindole (I) isolated. Neutralized with HBr and evapd. to dryness the residue was dissolved in Me_2CO and Et_2O added to give long needles of I.HBr, m. 148-9°; yield 70%. A further yield was obtained from the mother liquor. I from I.HBr, b. 187.5-8°, d_4^{25} 0.9103, n_D^{25} 1.47432, M. R. 42.66 (calcd. 42.96). I.HCl is hygroscopic. I.MeI, m. 233-4° (decompn.). Picrate, m. 178-9° (decompn.). Benzene-sulfonyl deriv., m. 125°. Chloroaurate, m. 118°. I.HBr in 60% EtOH was treated with MeI, then with Ag_2O and filtered. After distn. of EtOH and H_2O the base b. 180-213°. This was extd. with Et_2O , dried with KOH and the Et_2O distd. The residue (II) b. 211-3° (yield 70%), d_4^{25} 0.8670, n_D^{25} 1.47196, M. R. 55.25 (calcd. 54.27). II.MeI, m. 212° (decompn.). Picrate, m. 146°. This is not identical with Braun's product (cf. Ber. 57, 399; 58, 385). Reduction of II with Pt black and 2 atoms H gave *cis-o*-dimethylaminopropylcyclohexane (III), b. 214°, d_4^{20} 0.8604, n_D^{20} 1.46386, n_D^{25} 1.4629, d_4^{25} 0.8564. Chloroaurate, m. 132°. Picrate, m. 173°. Methiodide, m. 186-7°. Mixed m. ps. on the picrate and chloroaurate confirm the compn. of III.

FOSTER DEE SNELL

Some *ms*-acridine derivatives. KURT LEHMSTEDT AND ERNST WIRTH. *Techn. Hochschule, Hannover. Ber.* 61B, 2044-9(1928); D. R. P. 440,771, 440,772.—Whereas most org. bases give with SO_2 unstable acid sulfites which decomp. again on drying or heating and with alkali bisulfites either do not react or undergo deep-seated changes when boiled a long time, acridines behave entirely differently. From the HCl salt of acridine (I) with SO_2 or with Na_2SO_3 or from I in alc. with SO_2 , Graebe obtained a very difficultly sol. red compd. (II), $(C_{13}H_9N)_2 \cdot H_2SO_3$, while from I.HCl and Na_2SO_3 or I and $NaHSO_3$ he obtained an easily sol. colorless compd. (III), $C_{13}H_9N \cdot NaHSO_3$, which is stable in the air and can be recrystd. from hot H_2O . The behavior of III indicates that it is not a simple salt but an addn. product, the Na salt of 9,10-dihydro-acridine-9-sulfonic acid (*acridan-*ms*-sulfonic acid*) (IV), $C_8H_4 \cdot CH(SO_3H) \cdot C_6H_4 \cdot NH$.

III slowly oxidizes in the air when it is moist or its solns. are evapd., changing into II, which with the calcd. quantity of alkali regenerates III and I. II is therefore the acridine salt of IV and can be also obtained from IV and the calcd. quantity of I.HCl. With Na_2SO_3 it is completely converted into III. III is very reactive; with alkalis it smoothly regenerates I and it can be used to isolate I from mixts. with other bases. With KCN in boiling alc. suspension it gives 9,10-dihydro-9-cyanoacridine (V), which with hydrolytic agents yields acridanol, the latter at once decomp. into H_2O and I. V forms with mineral acids salts, which, however, are strongly hydrolyzed. It is readily dehydrogenated to 9-cyanoacridine (VI), in which the CN group is held very firmly so that the VI can easily be sapond. to the amide and acid. Its HCl salt can be isolated in anal. pure form. The alc. soln. of VI smells faintly of $(CN)_2$ and when refluxed a long time yields a compd. $C_{20}H_{20}N_2$ (VII), apparently 9,10,9',10'-tetrahydro-9,9'-diacridyl, which at its m. p. decomp. into an equimol. mixt. of I and 9,10-dihydroacridine. VI (76% from 28.3 g. III refluxed in alc. with KCN, freed from the alc. by distn. and of a red impurity by rubbing with very dil. NaOH, washed with H_2O and allowed to stand 1 day in the air), light yellow, m. 180.5° (186°, cor.); HCl salt, brownish; picrate, yellow, m. 229°. Acridine-9-carboxamide (prepd. by H. MAURER) (1.4 g. from 1.5 g. VI with 10 cc. 90% H_2SO_4 heated 2 hrs. on the H_2O bath), yellow, m. 283-4°. Acid (1.3 g. from 1.5 g. VI and 15 cc. 90% H_2SO_4 heated 2 hrs. on the H_2O bath, then treated with 4.0 g. solid $NaNO_2$ and heated another 2 hrs.), decomp. 289-90°. Acridine-9-thioamide (84% from VI in boiling alc. with excess of colorless alc. $(NH_4)_2S$), yellow, m. 240°. V is prepd. like VI except that after refluxing the hot alc. soln. is filtered from the Na_2SO_3 , quickly cooled and filtered from the reddish leaflets which sep.; the residue is then shaken in C_6H_6 with 5% NaOH to remove the red impurity and evapd. The V seps. in leaflets, m. 146°, forms colorless solns. in alc., Et_2O , C_6H_6 and Me_2CO and a yellow soln. in AcOH, is quite stable toward light and toward the air when dry but when moist (also in alc.) it is dehydrogenated, free alkalis greatly accelerating

the oxidation. Its salts are green. *Picrate*, olive, m. 222° . VII, m. completely 214° if kept at this temp. long enough, changes completely into I in boiling PhNO_2 .

C. A. R.

1,3,4-Oxiazines. II. J. VAN ALPHEN, Univ. Leiden. *Rec. trav. chim.* 47, 909–19 (1928); cf. C. A. 22, 2566.—Mogoketo-oxiazines with the keto group in the 5-position may be prep'd. by the action of ClCH_2COCl on β -acylphenylhydrazines: $\text{PhNHNHCOR} + \text{ClCOCH}_2\text{Cl} \rightarrow \text{PhN}(\text{COCH}_2\text{Cl})\text{NHCOR} + \text{HCl}$ and removal of a mol. of HCl from the product. α -Chloroacetyl- β -acetylphenylhydrazine (I), prep'd. by boiling 10 g. ClCH_2COCl and 13.5 g. PhNHNHAc in 50 cc. C_6H_6 for 1 hr., m. 131° . On boiling I with an excess of PhNH_2 for 5 min. was obtained α -N-phenylaminoacetyl- β -acetylphenylhydrazine (II), m. 140° , which is converted into α -N-phenylaminoacetyl-phenylhydrazine (III), m. 157° , on hydrolysis with 20% H_2SO_4 and alc. With BzH III gives α -N-phenylaminoacetyl- β -benzylidenephylhydrazine, m. 194.5° . I was converted into Δ^1 -2-methyl-4-phenyl-5-keto-1,3,4-oxiazine (IV), m. 65° , on heating 25 g. with 50 cc. dry acetone and 15 g. K_2CO_3 in a sealed tube for 4 hrs. at 100° . In a way analogous to the prep'n. of I, α -bromoacetyl- β -isobutyrylphenylhydrazine was prep'd. from PhNHNHCOCHMe_2 and BrCH_2COCl ; the substance could not be induced to cryst. and was converted into Δ^1 -2-isopropyl-4-phenyl-5-keto-1,3,4-oxiazine, (V) m. 40° , in the way described for the prep'n. of IV from I. By means of the methods already described, the following compds. were prep'd.: α -chloroacetyl- β -benzoylphenylhydrazine (VI), m. 198° , from ClCH_2COCl and PhNHNHBz ; α -N-phenylamino-acetyl- β -benzoylphenylhydrazine, m. 159° , from VI and PhNH_2 ; Δ^1 -2,4-diphenyl-5-keto-1,3,4-oxiazine (VII), m. 96° , from VI and K_2CO_3 in acetone or on heating with NH_3 in a sealed tube. The oxiazine VII slowly dissolves in alkalis, passing into the enolic form VIII.

C. F. VAN DUIN

New reaction of certain diazosulfonates derived from β -naphthol-1-sulfonic acid. **II. Constitution of nitro- and aminophenylphthalazones.** FREDERICK M. ROWE AND ESTHER LEVIN. Leeds Univ. *J. Chem. Soc.* 1928, 2550–5; cf. C. A. 20, 1802.—Heating 10 g. 1-hydroxy-3-[4'-nitrophenyl]-1,3-dihydrophthalazine-4-acetic acid (see Part I), 50 cc. concd. H_2SO_4 and 60 cc. H_2O for 2 hrs. causes the elimination of AcOH and gives 4'-nitro-3-phenylphthalaz-1-one (I) ($\text{R} = \text{C}_6\text{H}_4\text{NO}_2$) yellow, m. 333° ; NaOH gives a bluish red color, changing to orange-brown on keeping; mineral acids form salts which are readily decomp'd. by H_2O ; *picrate*, bright yellow, m. 218° , appears to be decomp'd. progressively by recrystn. from EtOH . Reduction with Na_2S gives 4'-amino-3-phenylphthalaz-1-one, m. 259° (previously described as the 4-one), while reduction with Zn and HCl gives 4'-amino-N-phenylphthalimidine, m. 198° . I and Me_2SO_4 in PhNO_2 give an orange-yellow ppt. (II), which gives a HCl salt and is unaltered by prolonged boiling with HCl ; crystn. of II from EtOH gives orange prisms (III), m. $138-41^{\circ}$, while crystn. from MeOH gives orange leaflets, m. $173-5^{\circ}$; heating III at 100° and then at 140° gives 4-keto-1-methoxy-3-[4'-nitrophenyl]-3,4-dihydrophthalazine (IV), pale yellow needles from EtOH , colorless needles from AcOH , m. 199° ; HBr-AcOH at 100° for 10 min. gives 1,4-diketo-3-[4'-nitrophenyl] tetrahydrophthalazine, m. 307° . $o\text{-HO}_2\text{CC}_6\text{H}_4\text{CHO}$ and $p\text{-O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$ in EtOH give the lactone form of o-carboxybenzaldehyde p-nitrophenylhydrazone, orange, m. 254° (Seekles, C. A. 18, 2506, describes this as a nitrophenylphthalazone); this is sol. in Na_2CO_3 , from which soln. acid ppts. the free acid, red, decompg. 218° and then m. 249° , which, on attempted crystn. from EtOH or $\text{C}_6\text{H}_6\text{N}$, gives 4'-nitro-3-phenylphthalaz-4-one, m. 258° ; it neither forms a *picrate* nor reacts with Me_2SO_4 . Reduction with Na_2S gives the 4'-amino deriv., pale yellow, m. 184° (HCl salt, needles; *Ac deriv.*, m. 233°). **III. Preparation of phthalazine, phthalazone and phthalimidine derivatives from m-nitroaniline.** F. M. ROWE, MAHMED AHEND HEMMAT AND E. LEVIN. *Ibid* 2556–63.—A filtered soln. of com. 1,2- $\text{C}_{10}\text{H}_6(\text{SO}_3\text{Na})\text{OH}$ in 220 cc. H_2O , stirred into the diazo soln. from 24 g. $m\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$ and 14 g. NaNO_2 in 60 cc. concd. HCl and 180 cc. H_2O , gives quant. the 3'-nitrobenzene-2-naphthol-1-diazosulfonate; this is washed free of acid with brine and dissolved in 600 cc. cold H_2O and 50 g. Na_2CO_3 in 250 cc. H_2O ; the yellowish brown soln. is added to 60 g. NaOH in 120 cc. cold H_2O and after standing overnight, the mixt. is rendered faintly acid with HCl , then neutralized with Na_2CO_3 , filtered, the filtrate rendered slightly acid and NaCl added, pptg. $\text{Na H 3-[3'-nitrophenyl]-1,3-dihydrophthalazine-4-acetate-1-sulfonate}$, orange-yellow prisms; the aq. soln. is de-

colored by Zn and NH_4OH ; ⁶boiling with concd. HCl or aq. H_2SO_4 gives 1-hydroxy-3-[3'-nitrophenyl]-1,3-dihydrophthalazine-4-acetic acid (V), pale yellow, m. 234° ; Me ester, pale yellow, m. 184° ; Et ester, pale yellow, m. 195° ; anilide, yellow, m. 239° (decompn.). Reduction of V with SnCl_2 and HCl gives the 3'-aminophenyl deriv. (VI), m. 252° (Ac deriv., m. 167°). Boiling VI with H_2SO_4 gives 91% of 3'-amino-3-phenylphthalaz-1-one, golden yellow, m. 210° (Ac deriv., m. 204°); reduction with Zn and HCl gives 3'-amino-N-phenylphthalimidine, m. 175° (Ac deriv., m. 204°); through the diazo reaction there results the 3'-HO deriv., m. 268° (Me ether, m. 122° ; Et ether, m. 115°). Heating V with H_2SO_4 gives 3'-nitro-3-phenylphthalaz-1-one, pale yellow, m. 324° (picrate, bright yellow, m. 234°); reduction gives VI. The action of Me_2SO_4 gives an orange-yellow ppt., which, crystd. from MeOH , gives golden yellow needles, m. $114-7^\circ$, or, from EtOH , golden prisms, m. $116-20^\circ$; heating these compds. at 100° , and then at 140° gives 4-keto-1-methoxy-3-[3'-nitrophenyl]-3,4-dihydrophthalazine, m. 182° ; demethylation with $\text{HBr}\cdot\text{AcOH}$ gives 1,4-diketo-3-[3'-nitrophenyl]tetrahydrophthalazine, m. 280° . $o\text{-HO}_2\text{CC}_6\text{H}_4\text{CHO}$ and $m\text{-O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$ give the lactone form of the phenylhydrazone, m. 240° ; boiling in PhNO_2 gives 3'-nitro-3-phenylphthalaz-4-one, m. 240° ; reduction with NaHSO_3 gives the 3'-amino deriv., m. 156° .

C. J. WEST

Curare alkaloids. I. Constitution of curine. ERNST SPÄTH, WOLFGANG LEITHE AND FRITZ LADECK. Univ. Wien. Ber. 61B, 1698-1709 (1928).—The 1st object of this work was to convert the cryst. curine (I), m. 212° , into the amorphous tubocurarine. The investigation was begun with samples of I provided by Böhm, but a welcome source of the material was discovered in *Radix pareirae bravae*, since it has been established with certainty that Scholtz's *d*-bebeerine (II), m. 214° , is the *d*-form of I. Of 3 samples of the root obtained from different firms, 1 yielded only small quantities of cryst. II, from another about 10% of the crude alkaloid was obtained as cryst. II and in the 3rd 30% of the crude base consisted of cryst. II. All the preps. of II were *d*-rotatory, however ($[\alpha]_D^{300^\circ}$). S. has found that mixing equal parts of *d*- and *l*-II raises the m. p. to 300° , and a mixt. of equal parts of I and II, recrystd. from CHCl_3 , likewise m. $299-300^\circ$. Crystallographic examn. also showed that I and II are identical in morphological and optical properties. When subjected to the Emden degradation, I and II yield in the 1st stage optically inactive bases (III) whose difficultly sol. HCl salts are identical in m. and mixed m. p., and the 2nd stage of the degradation gives in good yield satd. N-free compds. (IV) likewise identical in m. and mixed m. p. Böhm gave $\text{C}_{18}\text{H}_{19}\text{O}_3\text{N}$ as the compn. of I while II has at various times been assigned the formulas $\text{C}_{17}\text{H}_{19}\text{O}_3\text{N}$, $\text{C}_{18}\text{H}_{19}\text{O}_3\text{N}$, $\text{C}_{18}\text{H}_{21}\text{O}_3\text{N}$ and $\text{C}_{21}\text{H}_{23}\text{O}_4\text{N}$. A series of microanalyses gave values agreeing well with the formula $\text{C}_{18}\text{H}_{19}\text{O}_3\text{N}$ except for the C values, which were generally a little low. This formula was also confirmed by the compn. of the IV, by MeO detns. on I and II and by the Cl contents of their HCl salts. Mol. wt. detns. on I in camphor gave values about 20% higher than calcd. for the simple formula, indicating some association. To det. whether II would yield a basic salt it was treated with 0.5 the quantity of HCl calcd. for complete neutralization but only 0.5 of the II formed a salt. As to the constitution of I, Böhm had found that it contains a phenolic HO and a MeO group, gives on distn. with Zn dust a substance which he believed to be a methoxyquinoline, and on fusion with alkali yields $3,4\text{-(HO)}_2\text{C}_6\text{H}_3\text{CO}_2\text{H}$. Scholtz in II found a MeO , a HO and a *N*-Me group, and on distn. with Zn dust obtained *o*-cresol. S., L. and L. on distn. with Zn dust (after sapon. of the MeO group to facilitate the reaction) obtained 1-methylisoquinoline, identified as the picrate. Böhm's product therefore was evidently not a methoxyquinoline. In view of the difficult racemizability of isoquinoline alkaloids the formation of III in the Emden degradation must be the result not of racemization but of the disappearance of the asym. structure.

The 2nd stage of the degradation gives NMe_3 along with IV, showing that the N atom in I carries a Me group and is present in a ring. Neither I, III nor IV gives mellophanic acid with HNO_3 , indicating the absence of a phenanthrene complex. Fusion with KOH of II, both before and after sapon. of the MeO group, and methylation of the product gave a mixt. of sublimable, difficultly H_2O -sol. acids consisting chiefly of veratricum and anisic acids. If, however, the HO group in II is methylated, oxidation with KMnO_4 gives neither of these acids and it may therefore be concluded that the $p\text{-HOC}_6\text{H}_4\text{CH}_2$ and $3,4\text{-(HO)}_2\text{C}_6\text{H}_3\text{CH}_2$ complexes are not present as such or as Me ethers in II or its Me ether. Although phenolcarboxylic acids do not withstand KMnO_4 oxidation, it seemed probable that by carefully controlling the quantity of KMnO_4 , any such acid formed in the oxidation of II could be isolated, at least in small quantities, and as a matter of fact $p\text{-HOC}_6\text{H}_4\text{CO}_2\text{H}$ was identified among the products by conversion into anisic acid. As all heating was avoided it may be assumed that the HO acid was originally present as such and not, perhaps, as a hydroxyphthalic acid. II must therefore contain a $p\text{-HOC}_6\text{H}_4\text{CH}_2$ complex whose HO group, however, is not free or methylated but in ether-like combination with the phenolic HO group of a 2nd C_6H_5 nucleus. No deriv. of $3,4\text{-(HO)}_2\text{C}_6\text{H}_3\text{CO}_2\text{H}$ could be obtained by oxidative degradation. The results thus far obtained indicate that I has the structure

The positions of the MeO groups and of the O bridge will have to be detd. with greater certainty when more material is available. The Böhm I, recrystd. from $\text{CHCl}_3\text{-MeOH}$, m. $221\text{--}1.5^\circ$ (evacuated tubes); the crystals obtained from MeOH contain solvent of crystn., which is lost in the air or, more quickly, on heating. Pure II has the same m. p. and likewise seps. with MeOH of crystn.; the solvate with C_6H_6 of crystn., m. 161° , is more stable than the MeOH compd. $[\alpha]_D^{20}$ for I ($\text{C}_6\text{H}_5\text{N}$, c 5.04) -328° , for II (c 4.70) 332° . II.HCl, m. $271\text{--}2^\circ$ (evacuated tubes) with gas evolution. Me ether of II, prepd. with CH_2N_2 , amorphous. III.HCl, $\text{C}_{20}\text{H}_{28}\text{O}_3\text{NCl}$, m. $238\text{--}41^\circ$ (evacuated tubes) with gas evolution. IV, $\text{C}_{18}\text{H}_{26}\text{O}_3$, m. $186\text{--}7^\circ$, is unchanged by Pd-charcoal and H. C. A. R.

The alkaloids of kurchee bark (*Holarrhena antidysenteria*). I. Two new alkaloids discovered in Indian *Holarrhena*. SUDHAMOY GHOSH AND NAGENDRA NATH GHOSH. School of Tropical Med. and Hyg., Calcutta. *J. Indian Chem. Soc.* 5, 477–82 (1928); cf. C. A. 21, 1850.—The analysis of kurchee bark for total alkaloids yielded about 1.2%, though by extn. on a com. scale only about 0.7% were obtained. In sepg. the ext., G. and G. succeeded in isolating 2 new alkaloids, *kurchicine* (I) and *kurchine* (II), besides the already known conessine (III). The sepn. was based on the 3 following facts: The tartrates of I and III are very slightly sol. in 95% alc., while II tartrate is freely sol. In petroleum ether, I is almost insol., III is fairly sol. and II very sol. I sulfate is almost insol., III sulfate rather sol. in cold H_2O . I, m. 175° , N content 8.53%; tartrate, amorphous; sulfate; HBr salt, $[\alpha] -18.75$ (in H_2O). II, m. 75° , N content 9.84%; sulfate, micro needles. The prepn. of II was very difficult because besides the sulfate, no cryst. salts could be obtained; the nitrate, hydrochloride, hydrobromide, tartrate, oxalate and phosphate, all failed to crystallize. The yield of I was 0.12% of the wt. of the bark. II was not obtained quant. on account of the difficulties mentioned, but it is supposed to form the largest part of the ext. The possibility of prepg. the alkaloids on a com. scale is briefly discussed. G. SCHWOCH

Alkaloids of *Corydalis cava*. XIII. Synthesis of *d*-corytuberine dimethyl ether. ERNST SPATH AND OTTO HROMATKA. Univ. Wien. *Ber.* 61, 1692–8 (1928); cf. C. A. 22, 4126.—[2-Nitrohomoveratroyl]homoveratrylamine (92% from $2,3,4\text{-O}_2\text{N(MeO)}_2\text{-C}_6\text{H}_2\text{CH}_2\text{CO}_2\text{H}$ converted with SOCl_2 at 60° into the chloride, m. 56° , which was then added to $3,4\text{-(MeO)}_2\text{C}_6\text{H}_3\text{CH}_2\text{NH}_2$ in C_6H_6), sinters 69° , m. 72° (evacuated tube); treated in 1.5–3-g. portions in 60 parts gently boiling PhMe with about 5 parts P_2O_5 , it gives 72% of the *dihydroisoquinoline deriv.* (I), m. $165\text{--}6^\circ$ (evacuated tube), sol. in about 25 parts hot MeOH, easily in very dil. HCl; methiodide, obtained in 95% yield by heating I with MeI 20 min. at 100° , crystals with 1.5 H_2O , m. $100\text{--}4^\circ$ and, anhyd., $179\text{--}82^\circ$ (decompn.), gives with freshly pptd. AgCl on the H_2O bath the metho-

chloride, crystals with 3 H₂O, m. 100–3°; this, refluxed in EtOH-HCl with Sn, gives 67% of the aminotetrahydroisoquinoline deriv., brown oil, 7.0 g. of which, diazotized in 2 N H₂SO₄ with titrated NaNO₂, then treated with "Naturkupper C" and reduced with Zn dust and HCl, yielded 2.58 g. corytuberine di-Me ether (II), b_{0.6} 200–40°. With *l*-tartaric acid, II yielded a *l*-bitartrate, m. 213–5° (mixed m. p. with II prepd. from corydine, 212–4°), $[\alpha]_D^{25} +147^\circ$ (H₂O); examn. under the microscope by LETTMER also revealed no difference in the cryst. form of the synthetic product and that obtained from corydine; methiodide, m. 238° (decompn.), the m. p. depending on the rate of heating. II was obtained in 0.23 g. yield from 0.3 g. corydine in MeOH with CH₃N₂. This synthesis confirms the correctness of the formula assigned to II by Gadamer. Cf.

C. A. 22, 4126.

The catalytic dehydrogenation of nicotine. A suitable method for the preparation of *N*-methyl-(3-pyridyl)-2-pyrrole (3,2'-nicotyrine). J. P. WIBAUT AND J. OVERHOFF. Univ. Amsterdam. *Rec. trav. chim.* 47, 935–9(1928).—3,2'-Nicotyrine has already been prepd. from nicotine by oxidation with alk. K₃Fe(CN)₆ (*Bull. soc. chim.* [2], 34, 449(1880)) and by oxidation with Ag₂O (*Ber.* 27, 2535(1894)); both these methods, however, give unsatisfactory yields. The researches of Zelinskii have shown that it is an easy matter to dehydrogenate catalytically a cyclohexane ring, but that a cyclopentane ring cannot be dehydrogenated in this way. In the present paper the catalytic dehydrogenation of nicotine is described. On distg. nicotine slowly through a tube contg. 2 g. 30% platinized asbestos, prepd. according to Löw-Zelinskii, and heated at 290–350°, the nicotine is largely dehydrogenated to 3,2'-nicotyrine. The most favorable temp. is 320° and isomerization does not occur, only unchanged nicotine and 3,2'-nicotyrine being obtained. After 1 passage of the nicotine through the tube, 73% is transformed into 3,2'-nicotyrine on repeating the dehydrogenation with the reaction product and with fresh platinized asbestos, an almost theoretical yield of 3,2'-nicotyrine is obtained. The m. p. of the 3,2'-nicotyrine picrate was found to be 168–9°. It thus appears that the 5-membered pyrrolidine ring can be dehydrogenated catalytically.

C. F. VAN DUIN

Flavanone glucosides. III. Reduction of flavone and flavanone derivatives. YASUHIKO ASAHINA AND MOTOTARO INUBUSE. Univ. Tokyo. *Ber.* 61B, 1646–50 (1928); cf. C. A. 22, 4526.—It was shown recently that naringenin (I), hesperitin and sakuranetin are flavanone derivs. and that the formation of red dyes on reduction is a characteristic property of the hydroxy- and methoxyflavanones. These dyes contain Cl and behave very much like the anthocyanidin salts. An attempt was therefore made to det. whether a flavone deriv. can be converted into a benzopyrylium compd. by reduction. Apigenin (II) with Mg and HCl gives at most an orange soln. but on gentle warming in alk. soln. with Na-Hg there is obtained a dirty orange-red soln. from which HCl ppts. a deep red dye, probably the flavylium salt, apigenidine chloride (III), although its properties do not agree entirely with those of Pratt and Robinson's synthetic product. A. and I. assume that the II is first simultaneously hydrated and reduced to IV, which by loss of H₂O forms the carbinol base V and this under the influence of the HCl rearranges into III. By analysis and spectrochem. investigation III is found to be identical with the dye obtained from I. This is explained by assuming that I is reduced to VI, which by loss of H₂O gives VII; VII is probably easily oxidizable and is converted by atm. O into V. Since quercetin gives with Na-Hg no substance converted into the red dye by HCl the 3 groups of substances—flavanones, flavones and flavanols—can be sharply distinguished from each other by their behavior on reduction; the hydroxyflavanols give red dyes only with Mg and HCl, the hydroxyflavones only with Na-Hg and the hydroxyflavanones both with acid and alk. reducing agents. III, dark red, does not m. 300°, sol. in alc. with yellowish red color changing to wine-red on addn. of NaOAc, alkali or NH₄OH, shows no fluorescence on diln. of the alc. soln. with much H₂O and addn. of a drop of concd. H₂SO₄. Dye, C₁₅H₁₁O₄Cl.H₂O, from sakuranetin, dark red, decomp. 236–7°, sol. in alc. with purple color, changed by NaOAc to dark wine-red and by alkalis to dark violet-blue. Dye, C₁₆H₁₃O₄Cl.2H₂O, from hesperitin, dark red, m. 231–2° (decompn.), sol. in alc. with yellowish red color,

changed by NaOAc or alkalis to orange-yellow, while NH_4OH produces no marked effect. The absorption spectra (measured by Y. SHIBATA) of the dyes are given.

C. A. R.

The digitalis glucosides. I. Digitoxigenin and isodigitoxigenin. WALTER A. JACOBS AND E. L. GUSTUS. Rockefeller Inst. *J. Biol. Chem.* 78, 573-81(1928).—The methods previously described (*C. A.* 21, 3902) in the investigation of the isostrophanthidin series were applied to digitoxigenin (I) and isodigitoxigenin (II). I dissolved in KOH in MeOH gives II, lustrous, sparingly sol. crystals, m. 271°. I and II have the same empirical formula, $\text{C}_{23}\text{H}_{34}\text{O}_6$, but II does not give the Legal test and does not react with nitroprusside. II reacts with 1 equiv. of alkali and when acidified with AcOH gives isodigitoxigeninic acid (III), identical with the *dixgenic acid* of Kiliani (*Arch. Pharm.* 1899, 237, 452) and Cloetta (*C. A.* 15, 707). III forms a Me hydroxyaldehyde acid ester (m. 128°) with CH_2N_2 . This ester exists in either the free aldehydic or lactol form. It forms a semicarbazone. With CrO_3 the ester forms a neutral substance $\text{C}_{24}\text{H}_{34}\text{O}_6$ which is a lactone ester. On sapon. and reacidification it gives isodigitoxigenic acid (IV). III treated with HBrO gives isodigitoxigenic acid, $\text{C}_{23}\text{H}_{34}\text{O}_6$, which differs from IV by the retention of the secondary OH group. The results are analogous to those found with isostrophanthidin and give evidence of the $\Delta^{\beta,\gamma}$ -character of the lactone ring of I. II. Gitoxigenin and isogitoxigenin. *Ibid* 79, 553-62.—Gitoxigenin is considered from its behavior to be a tri-HO tetracyclic hydroaromatic $\Delta^{\beta,\gamma}$ -lactone, $\text{C}_{24}\text{H}_{34}\text{O}_6$. The following compds. were prepd.: gitoxigenin, m. 231-2°; gitoxigenon, m. 206-7°; dihydrogitoxigenin, m. 205-7°, isogitoxigenin, $\text{C}_{23}\text{H}_{34}\text{O}_6$, m. 249-50°; isogitoxigeninic acid, m. 152-3°; its Me ester, m. 145°; Me isogitoxigenonate, m. 170-2°; the acid, $\text{C}_{21}\text{H}_{30}\text{O}_6$, m. 252-3°; and its Me ester, m. 180°. A. G.

Constitution of some Indian essential oils. XXV. *l*- α - and *l*- β -Curcumenes. B. SANJIVA RAO AND JOHN L. SIMONSEN. Indian Inst. of Science, Bangalore. *J. Chem. Soc.* 1928, 2496-505; cf. *C. A.* 22, 2028.—Rao, Shintre and Simonsen (*C. A.* 21, 798) isolated from the essential oil occurring in the rhizomes of *Curcuma aromatica*, Salish., a sesquiterpene to which they gave the name *l*-curcumene; a further study shows that this is a mixt. of at least 2 hydrocarbons, which cannot be sepd. by fractional distn. through a 4-pear Young still head but when treated with AmNO_2 and HNO_3 the *l*- α -curcumene (I) seps. as the nitrosate (II), the yield varying from 2.3 to 4.5 g. from 10 g. of the mixt., depending upon the sample used. I is also obtained by satg. the mixt. with HCl, filtering off the tri-HCl deriv. (see below) and fractionating the I HCl, b_8 150-5°; heating with AcOH and AcONa gives an impure I. II and PhCH_2NH_2 in EtOH, boiled 1 hr., give *l*- α -curcumenenitrolbenzylamine, m. 102-4°, $[\alpha]_D^{30}$ -19.5° (MeOH, c 2.46). II, heated with an equiv. quantity of EtOH-KOH for 20 min., gives *l*-oximino- α -curcumene, b_7 182-5°, d_{30}^{30} 0.9817, n_D^{30} 1.5134, $[\alpha]_D^{30}$ -27.2°; titration with Br indicates 1 double bond; Bz deriv., m. 84-5°; HCl salt, m. 135-6°, is not acted on by cold alkali; reduction with Na and EtOH gives *l*-dihydro- α -curcumenylamine, b_{17} 151-2°, d_{30}^{30} 0.9026, n_D^{30} 1.4983, isolated as the H oxalate, m. 143-4°, crystg. with $1\text{H}_2\text{O}$, lost at 100°; Ac deriv., m. 109-10°. MeI gives *l*-dihydro- α -curcumenyltrimethylammonium iodide, m. 163-4° (poor yield); the hydroxide could not be purified, but distn. at 400° gave a mixt. of very pure I, b_7 128-30°, d_{30}^{30} 0.8633, n_D^{30} 1.4944, $[\alpha]_D^{30}$ -22.9°, and *l*-dimethyldihydro- α -curcumenylamine, b_{18} 130-40°, d_{30}^{30} 0.8824, n_D^{30} 1.4913, $[\alpha]_D^{30}$ -23.0°. I is not reduced by Na and EtOH and is not isomerized by heating at 380° in an inert atm. It does not yield a C_{10}H_8 deriv. when heated with S or Se at 270°; in AcOH a drop of H_2SO_4 gives a yellow color, gradually changing to pink. Catalytic reduction of I gives the hexahydro deriv., b_7 128°, d_{30}^{30} 0.8283, n_D^{30}

1.4592, $[\alpha]_D^{30}$ 0°. The original mixt., on treatment with HCl, ppt. *l*- β -curcumene (III) as the tri-HCl deriv., from which III is regenerated by heating with AcONa in AcOH at 140° for 8 hrs.; III b₇ 128–30°, d_{30}^{30} 0.8810, n_D^{30} 1.4940, $[\alpha]_D^{30}$ –27.9°; titration with Br indicates the presence of 3 double bonds; in AcOH H₂SO₄ gives a deep brown color. III, heated with 10% H₂SO₄, yields a dicyclic terpene (?), b₇ 115–7°, d_{30}^{30} 0.8932, n_D^{30} 1.4936, $[\alpha]_D^{30}$ –11.9°. III is not reduced by Na and AmOH but is isomerized, giving a compd. b₇ 129–30°, d_{30}^{30} 0.8780, n_D^{30} 1.4936; isomerization was also observed on heating at 380° in an inert atm. No C₁₀H₈ deriv. was formed with S or Se at 270°. Catalytic reduction of III gives the *hexahydro deriv.*, b₇ 128°, d_{30}^{30} 0.8283, n_D^{30} 1.4552, $[\alpha]_D^{30}$ 6.3°. Oxidation of I or III with Bz₂O₂ confirms the presence of 3 double bonds. Dihydro- α -curcumenylamine has no characteristic physiol. action beyond a general toxic action.

C. J. WEST

Brasilin and hematoxylin question. VIII. Reduction of trimethylbrasilone and tetramethylhematoxylone. P. PFEIFFER, O. ANGERN, E. HAACK AND J. WILLEMS. Univ. Bonn. *Ber.* 61B, 1923–32(1928); cf. C. A. 22, 2360.—In earlier papers was described the synthesis of trimethylanhydrobrasilin (I), its reduction to trimethyldeoxygenbrasilin and the oxidation of the latter to trimethylbrasilone (II), the known oxidation product of trimethylbrasilin (III). The corresponding products of the tetramethylhematoxylin (IV) series, which differ from those of the III series only in having another OMe group on the C atom, were likewise synthesized. By these syntheses the structure of the natural brasilin and hematoxylin was established except for the position of the alc. HO group. To complete the synthesis of the natural products it remained to reduce II to III. This has not as yet been successfully effected, substances isomeric but not identical with the III and IV having been obtained. The results so far obtained are published now because of the appearance of the paper of Perkin, Ray and Robinson on the same subject (C. A. 22, 3414). II in AcOH with H and Pt sponge at room temp. gives quite smoothly a compd. C₁₆H₂₀O(OMe)₃(OH)₂·H₂O (V), m. 151–2°, probably identical with that obtained by P., R. and R. with amalgamated Al and to which they assigned the formula C₁₆H₂₀O₆·0.5H₂O. To be sure, their compd. m. 129° but its color reactions agree completely with those of V; both substances dissolve in concd. H₂SO₄ with deep bluish red color, changing to brown on heating and assuming an intense green fluorescence. V is also obtained in good yield in AcOH–C₆H₆ with Mg. It is thought not to belong to the true brasilin series but to be derived from the tautomeric form of II and to have the structure VI; it cannot be converted back into II with CrO₃ but gives instead a *carboxylic acid* (VII), m. 225°. With Na–Hg in AcOH–EtOH it gives a compd. C₁₆H₁₈O(OMe)₃OH (VIII), isomeric with natural III. Tetramethylhematoxylone (IX) behaves on reduction much like II; with H and Pt sponge it gives in good yield a compd. C₁₆H₂₀O(OMe)₄(OH)₂ (X), also obtained with Mg in AcOH–C₆H₆; in the latter reaction are formed a no. of other products, 2 of which have been isolated: C₂₀H₂₀O₇ (XI) and C₁₆H₁₈O(OMe)₄OH (XII), isomeric with natural IV. I cautiously treated with Br gives, through a red intermediate product which could not be isolated, by primary addn. of Br at the double bond and secondary cleavage of HBr, the *pyrylium salt* XIII, while with I is smoothly obtained the *diiodide* XIV, almost insol. in H₂O, which, when shaken in H₂O suspension with AgNO₃, forms at first a red soln., presumably of the corresponding iodonitrate, but in a short time it splits off HI and forms a pyrylium salt with green fluorescence. XIII, orange, darkens above 170° and gradually carbonizes, dissolves in H₂O with orange color and green fluorescence. XIV, dark red-brown, m. 175° (decompn.), sol. in MeCN with yellow-red color gradually changing to greenish brown-yellow. V (2 g. from 3 g. II with H and Pt sponge) after standing 1–2 days over CaCl₂ begins to sinter and evolve gas at 125° and m. clear 150–1°, but if kept over the CaCl₂ 14 days, when it has the compn. of the monohydrate, it m. 151–2° sharply without previously sintering; *p*-nitrobenzoate, light yellow, softens 98°, m. 103–5°. In the prepn. of V with Mg there are also formed a compd., m. 267° (decompn.), sol. in concd. H₂SO₄ with dark green color, and another compd., m. 285°, sol. in H₂SO₄ with pure yellow color soon becoming brown. VIII (2.6 g. from 3 g. II), m. 133–4°, gives a blood-red color with concd. H₂SO₄ and with Br vapor a violet-black color, which soon disappears; *acetate*, m. 123–4°. X (1.8 g. from 3 g. IX with Pt sponge and H), m. 185–8°, sol. in concd. H₂SO₄ with deep violet-blue color, gives in the solid state no color with Br; *acetate*, m. 150–2°; *p*-nitrobenzoate, yellow, m. 177–8°. XI, m. 283° (effervescence), sol. in concd. H₂SO₄ with green-yellow color soon changing to green-brown. XII, crystals with 1 H₂O, m. 188–92°, sol. in concd. H₂SO₄ with purple color, unchanged by Br vapors.

C. A. R.

Strophanthin. XV. Hispidus strophanthin. WALTER A. JACOBS AND ALEXANDER HOFFMANN. Rockefeller Inst. *J. Biol. Chem.* 76, 531-7(1928).—The strophanthins of *Strophanthus hispidus* seeds were investigated by the methods previously applied (C. A. 20, 3013; 22, 1131) to *Strophanthus kombe*. The aglucone of hispidus strophanthin was found to be identical with the strophanthidin of the *kombe* variety. Cymarín occurred both free and combined with glucose. The cleavage of the cymarín glucoside was accomplished only slowly and incompletely by the special enzymes in the hispidus seeds. Where cleavage did occur only glucose and cymarín were identified. Hispidus strophanthin is thus chemically different from *K*-strophanthin. **XVI. Degradation in the isostrophanthidin series.** WALTER A. JACOBS AND EDWIN L. GUSTUS. *Ibid* 539-52.—Di-Me anhydro- α -isostrophanthonate was oxidized with KMnO_4 . From the reaction mixt., undephanthotriacid di-Me ester, $\text{C}_{24}\text{H}_{32}\text{O}_9$, m. 179-80°, and the corresponding tri-Me ester, m. 154.5°-5.5°, were obtained. From the latter the ester oxime, m. 188-9°, the phenylhydrazone, m. 196.5-7.5°, and the phenyl- γ -lactazam, m. 155-7°, solidifies and remelts at 240-2°, were obtained. The following compds. were also prepd.: undephanthotriacid mono-Me ester, m. 237-40°; duodephanthondiacid, $\text{C}_{21}\text{H}_{28}\text{O}_7$, m. 253-4°: its di-Me ester, m. 166-7°: its tri-Me ester oxime, 187-9°: the lactone triacid di-Me ester, $\text{C}_{26}\text{H}_{32}\text{O}_{10}$, m. 188-90°; the lactone triacid tri-Me ester, $\text{C}_{26}\text{H}_{34}\text{O}_{10}$, m. 236-7°; and the lactone triacid, $\text{C}_{28}\text{H}_{28}\text{O}_{10}$, m. 193-5°. The bearing of these findings on the structure of the strophanthidin mol. is discussed.

ARTHUR GROLLMAN

Periplocymarin and periplogenin. WALTER A. JACOBS AND ALEXANDER HOFFMANN. *J. Biol. Chem.* 79, 519-30(1928).—Periplocymarin, $\text{C}_{30}\text{H}_{40}\text{O}_8$, was prepd. from the stems and branches of *Periploca graeca* obtained from various sources. It crystd. from MeOH as lustrous needles contg. approx. 1 mol. MeOH which was lost on drying at 100° under reduced pressure. It sintered at 138° and m. 148°. By treating periplocymarin with HCl was obtained periplogenin, small prisms, m. 135-40° with effervescence. Analyses of this material were in best agreement with the formula $\text{C}_{23}\text{H}_{34}\text{O}_6$. By hydrogenation with Pt black, periplogenin was converted to dihydroperiplogenin, $\text{C}_{23}\text{H}_{36}\text{O}_6$, m. 204°. By sapon. with NaOH in MeOH isoperiplogenin was formed. The lactone acid of the latter compd., isoperiplogenic acid, $\text{C}_{23}\text{H}_{34}\text{O}_6$, was obtained as lustrous 6-sided leaflets, with 0.5 mol. H_2O , m. 215° with effervescence. With CH_3N_3 in acetone, the Me isoperiplogenate, $\text{C}_{24}\text{H}_{36}\text{O}_6$, m. 252°, was obtained.

ARTHUR GROLLMAN

Gitoxin. A. WINDAUS, K. WESTPHAL AND G. STEIN. Univ. Göttingen. *Ber.* 61B, 1847-55(1928).—Cloetta (C. A. 20, 2724) describes his digitalin as m. 282° (cor.) on rapid heating, remaining unchanged up to 265°, then beginning to become somewhat yellowish and effervescing 282°, while W. and Schwarte reported for their gitoxin (I) that it m. 266-9° (uncor.) and that this m. p., being a decompn. point, is not very characteristic, and it has been found that this decompn. point can be raised above or brought below 282°, depending on the rate of heating; to the differences in the m. ps. of the 2 substances no great significance can, therefore, be attached. The gitoxigenin (II) obtained, along with digitoxose, by the cleavage of I, readily loses 2 mols. of H_2O to form a dianhydro deriv. identical with the digitaligenin (III) prepd. from the seed glucoside of *Digitalium verum*, to which the formula $\text{C}_{44}\text{H}_{62}\text{O}_8$ had been assigned by

W. and Bandte. II was therefore given the C_{24} formula $C_{24}H_{36}O_6$, while Cloetta assigns to his bigitaligenin the formula $C_{23}H_{34}O_6$. Schwarte's and Cloetta's analyses for II and its derivs. do not agree well and the authors have accordingly prepd. all the known derivs. anew and have had them analyzed in A. Schoeller's micro-anal. lab. and Karrer (Zürich) and Pregl (Graz) have also made many control analyses for them; they believe that the compns. of II and its derivs. may now be considered as definitely established, as follows: I, $C_{41}H_{64}O_{12}$; II, $C_{23}H_{34}O_6$ (the Ac derivs. are apparently not suitable for detg. the compn. of II, for in their prepn. mixts. of mono-, di- and tri-Ac derivs. may be formed). III, $C_{23}H_{34}O_6$. A repetition of Cloetta's hydrogenation of II with Pt black has led the authors to believe that his supposed di- and tetrahydro derivs., m. 212° and 241°, resp., are really stereoisomeric dihydro derivs., $C_{23}H_{36}O_6$; not only can the 212° compd. be converted into the 241° compd. but both yield the same *di-anhydrodihydrogitoxigenin* (IV), $C_{23}H_{32}O_6$. The 241° compd. shows $[\alpha]_D^{20} -48.74^\circ$ (MeOH). IV, readily obtained with HCl, m. 166°, is converted in alc. by H_2 and Pt black with extraordinary rapidity into a mixt. of stereoisomeric *tetrahydrodianhydrodihydrogitoxigenins*, $C_{23}H_{36}O_6$, the less sol. of which (V) m. 214°, $[\alpha]_D^{20} 75.7^\circ$ (alc.), and on cautious oxidation in AcOH with Beckmann's mixt. gives *tetrahydrodianhydrogitoxigenone* (VI), $C_{23}H_{34}O_6$, m. 207°, $[\alpha]_D^{20} 85.9^\circ$ ($CHCl_3$), probably identical with Bandte's hexahydrodigitaligenone, m. 205-7°; *oxime*, m. 215° (B., 205.6°). Reduction of the ketone by Clemmensen's method gives the *lactone* $C_{23}H_{36}O_6$, m. 173° (B., 168-9°), $[\alpha]_D^{18} 71^\circ$ ($CHCl_3$). The ketone in AcOH with excess of CrO_3 mixt. at 70° gives the *dicarboxylic acid* $C_{23}H_{34}O_8$ (VII), m. 282°, $[\alpha]_D^{20} 100^\circ$ (AcOH), whose *di-Me ester*, prepd. with CH_3N_3 , m. 163°, $[\alpha]_D^{20} 82.3^\circ$ ($CHCl_3$). Bandte and Schwarte by addn. of 6 atoms of H to III had obtained products, m. 186-7°, which they believed to be homogeneous, but it has been found that on careful fractional crystn. they can be sepd. into V and more sol., lower-melting isomers with $[\alpha]_D$ 40-50°; the 186° mixts. yield an *Ac deriv.*, m. 156° and a *Pr deriv.*, m. 163-4° (also probably mixts. of stereoisomers); oxidation with CrO_3 gives, together with some VI, chiefly a more sol. product, m. 150-85°, yielding on reduction a lactone m. around 145° and on oxidation an *isomer* (believed to be homogeneous) of VII, m. 278°, $[\alpha]_D^{18} 71^\circ$ (AcOH), whose *di-Me ester*, m. 171-2°, $[\alpha]_D^{22} 40^\circ$ ($CHCl_3$). Distd. at 280° under 1 mm. the acid gives a *ketone* $C_{22}H_{32}O_6$, m. 206°; *oxime*, m. 248°. The above results indicate that II is a singly unsatd. trihydroxy-lactone and the alc. group remaining in III and IV is secondary and adjacent to a CH_2 group in a hydroaromatic 6- (or 7-) membered ring. C. A. R.

Xanthophyll. I. Catalytic hydrogenation. L. ZECHMEISTER AND P. TUZSON. Univ. Pécs. Ber. 61B, 2003-9(1928).—After the no. of double bonds in carotin, $C_{40}H_{56}$ (I), had been established by catalytic hydrogenation and its decolorization during the reduction had been followed colorimetrically (C. A. 22, 4533), it became of interest to study in the same way the 2nd carotenoid of the green leaf, xanthophyll, $C_{40}H_{56}O_2$ (II). It behaves almost exactly like I, taking up 22 atoms H_2 and its color decreasing almost exactly proportionally to the quantity of H_2 absorbed up to 16 atoms, when it becomes colorless. I and II therefore seem to have the same unsatd. skeleton with 8 conjugated, rapidly satd. double bonds and 3 more slowly reacting double bonds which play no role in the production of the color. On the basis of the data at present available, the simplest view as to the relationship between the 2 pigments is that I contains 2 alkyl, II 2 alkoxy groups at corresponding positions in their mols. As perhydrocarotene is optically inactive while *perhydroxanthophyll* (III) is active, the O atoms must occupy a position which produces asymmetry or, if it should happen that perhydrocarotene has some activity, even though immeasurably small, they increase this activity extraordinarily. III is a colorless or very faintly yellowish, thick oil, mol. wt. in freezing C_4H_6 564-90, $[\alpha]_D^{24} -9.2^\circ$ (Et_2O), -9.8° (C_6H_6). C. A. R.

Remark on my address before the German Chemical Society (porphyrins and their synthesis). HANS FISCHER. Techn. Hochschule München. Ber. 61B, 1596 (1928); cf. C. A. 22, 1163.—F. does not feel called upon to make any reply to Schumm (C. A. 22, 2381). C. A. R.

The modifications of hydroxyhemin. A. HAMSÍK. Univ. Brünn. Z. physiol. Chem. 178, 67-74(1928).—Three modifications are distinguished, α - and β -hydroxyhemins and pseudohemin. α -Hydroxyhemin (α -hematin) is the original unaltered form. β -Hydroxyhemins (β -hematins) are products obtained from the above by mild treatment with acids and bases, while pseudohemins are obtained from either of the foregoing by more drastic treatment and are therefore more profoundly altered. The β -derivs. differ from the α -form in their greater soly. in AcOH and pyridine, their

cryst. form, inability to form anhydrides and greater difficulty of crystn. They combine with Cl less readily and the products give up Cl more easily. They can be recrystd. from AcOH-NaCl after dissolving in pyridine-CHCl₃. When deferrated by MeAc-SnCl₂-HCl they yield less protoporphyrin and more of a porphyrin characterized by its sol. Na salt and its alk. spectrum. The pseudohemins are still more sol. and more difficult to ppt., they give up Cl very readily and cannot be crystd. from AcOH-NaCl after dissolving in pyridine-CHCl₃. They yield less protoporphyrin and mainly a brown-green-red porphyrin. Some of the cryst. hemins are probably chem. individuals, but after dissolving in bases and pptg. by acid the products are mixts.

A. W. DOX

The constitution of the bile acids. XIV. The condensation of dehydrocholic acid with itself and with aromatic aldehydes. W. BORSCHÉ AND E. FESKE. Univ. Frankfurt. *Z. physiol. Chem.* 178, 148-55(1928); cf. *C. A.* 22, 3169.—When dehydrocholic acid, C₂₄H₃₄O₈ (I), is heated 3-4 hrs. in a bomb tube at 250°, 2 mols. condense with splitting out of H₂O to form a *didehydrocholic acid*, C₄₈H₆₆O₈, m. 309-10°, in 50% yield. The same product was obtained in 30% yield by heating I 4 hrs. in an open vessel in a current of CO₂, and in 50% yield by satg. I in AcOH with dry HCl and allowing to stand for 1 week. The *di-Me ester*, m. 265°, was prepd. by suspending the acid in Et₂O and treating with CH₃N₃, and the *di-Me ester pentoxime*, m. 229°, by boiling the ester in MeOH with NH₂OH.HCl and NaOAc. Oxidation of the acid with alk. KMnO₄ gave no characteristic product, but hydrogenation in AcOH with Pt catalyst at 2.5 atm. and 100° yielded *pentahydroxydicholanic acid*, m. 245-6°. I condenses also with 2 mols. of BzH when the mixt. is heated 4 hrs. at 250-5°, or allowed to stand at room temp. with AcOH-HCl, yielding *β-dibenzaldehydcholic acid*, m. 219-20°. This is isomeric with a dibenzal deriv. previously prepd. by condensation in the presence of NaOH. Although at least 2 more CH₂ groups are present in I, these do not react even with an excess of BzH. *Di-p-chlorobenzaldehydcholic acid*, m. 249°, was prepd. by a similar condensation between I and *p*-ClC₆H₄CHO in the presence of AcOH satd. with HCl.

A. W. DOX

Preparation of hemin derivatives by pyro reactions. II. 1. Préparation of pyratin from hemin by the resorcinol fusion. 2. Preparation and properties of pyroporphyrin. 3. Deferration of porphyrins in the "iron-phenol fusion" and transformation of iron porphyrins by phenols and phenol-sulfuric acid. O. SCHUMM. Hamburg Univ. *Z. physiol. Chem.* 178, 1-18(1928); cf. *C. A.* 22, 3168.—By heating hemin with molten resorcinol at 180-90° an almost quant. yield of *pyratin* is obtained, a substance probably identical with copratin. It may be converted into the cryst. *chloride* by dissolving in boiling AcOH and adding a little HCl, or by dissolving in pyridine, dilg. with CHCl₃ and pouring into boiling AcOH contg. HCl. It crystals in 3 different forms. Unlike hemin, hematin, hematohematin and their Me derivs., it dissolves in concd. H₂SO₄ with a violet color. Treatment with AcOH-N₂H₄ by removal of Fe converts it into *pyroporphyrin*, which is probably identical with copratoporphyrin. When pyratin is heated in paraffin to 360° and then after cooling treated with AcOH-N₂H₄ it yields a substance differing from pyroporphyrin only in its insoly. in alkali. The product is probably a decarboxylated pyroporphyrin. Conversion of pyratin into pyroporphyrin may be effected also by dissolving in PhOH and treating with (CO₂H)₂. Pyroporphyrin, like copratoporphyrin, contains 2 CO₂H groups and forms a Me ester, m. 218-23°. Pyratin may be obtained also from hemoglobin, though less readily than from hemin, but not from mesohemin or mesoporphyrin by the resorcinol fusion. Other phenols, *e. g.*, *o*- and *p*-C₆H₄(OH)₂, 1,2,3- and 1,3,5-C₆H₃(OH)₃ and the HO-free compds. C₁₀H₈, anthracene and camphor are not suited to this reaction. When pyroporphyrin is boiled with PhOH and Fe powder or FeO an Fe complex is formed. Other metals, as Cu and Mn, may be introduced in the same way. Treatment of hemin with a mixt. of PhOH and H₂SO₄ yields Fe-contg. or Fe-free hemin derivs. according to the proportions of the reaction mixt. At higher temps. the Fe thus removed tends to recombine with the porphyrin.

VITORIA, P. E.: *Química del carbono (teórica y práctica)*. Barcelona: Casals. 894 pp. Reviewed in *Chimie et industrie* 20, 402(1928).

Oxygenated organic compounds. I. G. FARBENIND. A.-G. -Brit. 286,010, Aug. 18, 1926. In producing alcs. and other oxygenated org. compds. by interaction of CO with vaporized aliphatic alcs. or esters as described, in Brit. 254,819 (C. A. 21, 2703), the presence of free Fe, Ni or Co or volatile compds. of these metals is excluded from the inner parts of the app., the catalysts and the reaction gases.

Organic acids. ÉTABLISSEMENTS TENCÉ ET COMPAGNIE FRANÇAISE D'APPLICATIONS CHIMIQUES RÉUNIS. (Émile Dubosc, inventor.) Fr. 638,567, Dec. 13, 1926. Org. acids are prepd. by making gaseous HCl, dry or damp, act on solid salts of org. acids either in the presence of water or a solvent in which the acid is more sol. than in water so as to obtain finally 2 liquid layers, one an aq. soln. of a chloride, the other the acid or a soln. thereof.

Sulfamic acids. I. G. FARBENIND. A.-G. Fr. 638,175, July 23, 1927. Sulfamic acids of secondary bases are prepd. by acting on the latter with chlorosulfonic acid or its salts or esters, SO₂, pyrosulfuric acid or analogous reagents, in the presence of an agent capable of fixing the acids and with (or without) a solvent or indifferent diluent. The bases are reformed by heating with an acid, so that the process may be used for the purification of the bases, e. g., carbazole may be sepd. from anthracene, and monosepd. from di-methylaniline.

Hydrogenating esters of aromatic carboxylic acids. I. G. FARBENIND. A.-G. Brit. 286,201, Feb. 26, 1927. Esters of aromatic carboxylic acids are hydrogenated in the nucleus by treatment with H at moderate pressure (suitably 25-40 atm.) in the presence of a Ni catalyst and with or without use of a solvent. With acids derived from C₁₀H₈ the addn. of H takes place only in the unsubstituted part of the nucleus. The resulting esters may be sapond. to produce acids. Co may be used with Ni in the catalyst. Examples are given of the hydrogenation of benzoic acid ethyl ester (to produce hexahydrobenzoic acid ethyl ester), phenylacetic acid ethyl ester (to produce hexahydrophenylacetic acid ethyl ester), salicylic acid methyl ester (to produce hexahydrosalicylic acid methyl ester), phthalic acid diethyl ester (to produce hexahydrophthalic acid diethyl ester), terephthalic acid dimethyl ester (to produce hexahydroterephthalic acid dimethyl ester), α -naphthoic acid ethyl ester (to produce 5,6,7,8-tetrahydro-1-naphthoic acid ethyl ester), and 2,3-aminonaphthoic acid ethyl ester (to produce 5,6,7,8-tetrahydro-2,3-aminonaphthoic acid ethyl ester).

Amines. GEORGES MIGNONAC. Fr. 638,550, Dec. 9, 1926. Primary amines are prepd. by catalytic hydrogenation of N compds. such as oximes or nitriles in the presence of NH₃. In examples, a mixt. of H, NH₃ and acetonitrile is passed over reduced Ni at 180° and EtNH₂ is collected. Similarly benzonitrile with reduced Cu at 250° gives benzylamine. A mixt. of benzyl cyanide, alc. and NH₃ is agitated in an atm. of H, and β -phenylethylamine is produced.

Alkylguanidines. SCHERING-KAHLBAUM A.-G. (formerly Chemische Fabrik auf Actien, vorm. E. Schering). Brit. 285,873, Feb. 24, 1927. A salt of a higher alkylamine is treated with cyanamide or a deriv. in the presence of a quantity of solvent which is insufficient to dissolve all the material. Thus diisoamylamine is converted into diisoamylguanidine, decamethylenediamine into diguanyldecamethylenediamine, δ -guanidinobutyl- γ -guanidinopropylamine into the corresponding triguanidine, methylaminoacetopyrocatechol into 2-amino-3-methyl-4(5)-dihydroxyphenyl(3,4)-glyoxaline and methylaminoacetophenol into 2-amino-3-methyl-4(5)-hydroxyphenyl(4)-glyoxaline.

Aromatic amino thiocyno derivatives. OSKAR SPENGLER and WERNER MÜLLER (to Grasselli Dyestuff Corp.). U. S. 1,687,596, Oct. 16. A soln. contg. the reaction product of a halide of sulfuric acid and a thiocyanate, e. g., a soln. formed from sulfuryl chloride and Pb(CNS)₂ in CCl₄, is caused to react with an aromatic amino compd., e. g., with diphenylamine in CHCl₃ to form 4,4'-dithiocyanodiphenylamine, m. 120°.

Coumarone derivatives. CHEMISCHE FABRIK AUF ACTIEN (formerly E. Schering). Fr. 638,483, Jun. 21, 1927. Alkylcoumarones are prepd. by heating to 280-320° the products of condensation of alkylphenols and ketones. In examples, the condensation product of *m*-cresol and acetone is heated to 300°. The distillate is fractionated, giving besides 3-methyl-6-isopropylphenol a dimethylcoumarone b. 98°. Similarly the condensation product of *p*-cresol and acetone gives besides 4-methyl-6-isopropylphenol a dimethylcoumarone b. 102°.

Mercaptans, etc. INTERNATIONALE NAHRUNGS- UND GENUSSMITTEL A.-G. Brit.

286,152, July 25, 1927. Furfuryl disulfides and mercaptans are made by treating furfural or a deriv. with sulfides or sulphydrates of the alkalis, earth alkalis or NH_3 , and reducing. Examples are given of the prepn. of furfuryl mercaptan and its nitrobenzoic ester, α -methylfurfuryl mercaptan and its *p*-nitrobenzoic ester, α -hydroxy-methyl-furfuryl mercaptan and methoxymethylfurfuryl mercaptan. Cf. C. A. 22, 4537.

Dinitro derivatives of perylene, etc. KARL STIEGER (to Felice Bensa). U. S. 1,688,837, Oct. 23.* Perylene or a deriv. such as a halide is suspended in glacial HOAc, the suspension is heated to about 100° and is treated with HNO_3 (produced *in situ* by reaction of KNO_3 and H_2SO_4) in the proportion of 2 mols. for each mol. of the compd. treated.

Isomeric thymols and menthols. SCHERING-KAHLBAUM A.-G. (formerly Chemische Fabrik auf Actien, vorm. E. Schering). Brit. 285,833, Feb. 22, 1927. The hydrogenated condensation products of crude cresol with acetone are sepd. into their components by fractional distn. (preferably *in vacuo*, which may be accompanied by freezing). Examples and details are given.

Derivatives of starch, cellulose and other carbohydrates. W. HARRISON. Brit. 286,331, Oct. 30, 1926. Stable and permanent derivs. are produced by oxidizing a carbohydrate compd. contg. a CSS group, in the presence of NH_3 or an NH_3 deriv. not contg. org. constituents such as hydroxylamine. Oxidizing agents which oxidize H_2S may be used such as ferricyanides, dichromates, peroxides, HNO_3 , SO_3 , ferric salts and air or O with or without O carriers. O may be used in the nascent state as generated by electrolysis. Examples are given of the use as starting materials of cellulose and starch xanthogenates and cellulose dixanthogenate. Brit. 286,332 specifies generally similar oxidations of like starting materials in the presence of an org. deriv. of NH_3 in which at least one atom of H is reactive and in which one or both of the other H atoms may be replaced by an alkyl, aryl or aralkyl group, e. g., alkylamines, arylamines such as aniline, aralkylamines, acid amides such as acetamide, benzamide or phthalamide, amino acids such as aminoacetic acid, amidines, urea and its derivs., cyanamide, dicyanodiamide, dicyanamide, guanidine and its derivs. and thiourea and its derivs. Products are obtained which may be used for making films, filaments, etc. Cf. C. A. 22, 4536.

Reducing aromatic nitro compounds. PAUL DIETERLE (to National Aniline & Chemical Co.). U. S. 1,689,014, Oct. 23. In reactions such as the production of aniline from PhNO_2 , FeS is used as a reducing agent.

Dehydration of alcohol. OVIDIO LEONORI. Fr. 636,551, June 24, 1927. Alc. for use as a fuel or in solvent mixts. is dehydrated by treating it with a mixt. of carbides of Ca, Ba, Mn, etc., which are decompd. by H_2O . Hydride of Ca or Al may also be added, and the H_2O may be first satd. with NH_3 .

Catalysts for the production of methanol. COMMERCIAL SOLVENTS CORP. Fr. 636,337, May 12, 1927. A catalyst for the production of methanol is made by reducing a Ni compd., e. g., $\text{Ni}(\text{NO}_3)_2$, with H at a temp. between 300 and 950° , preferably 500 – 600° .

Catalysts for methanol production, etc. I. G. FARBENIND. A.-G. Brit. 286,284 March 3, 1927. Catalysts of high mech. stability, especially those of the metal oxide type, are obtained by the addn. of water-sol. Mg salts such as the sulfate, chloride or nitrate to the other components. Examples are given of the use of ZnO with MgCl_2 together to form a mass which after heating is treated with chromic acid or alkali metal dichromate, to form a catalyst suitable for MeOH production from CO and H at temps. of 400 – 450° under 200 atm. pressure.

Dehydrating secondary alcohols. SYLVAN R. MERLEY (to Doherty Research Co.) U. S. 1,688,731, Oct. 23. Crude amyl alc. from petroleum products or other similar heavy secondary alc. liquids contg. small quantities of low-boiling "off-odor" compds. are rectified with a substantially dry alc. such as secondary BuOH of lower b. p. than that of the alc. to be dehydrated and forming a const.-b. p. mixt. with water and causing the temp. of initial distn. of the mixt. to be higher than the b. p. of the liquid to be dehydrated.

Olefin alcohols. FRED W. LOMMEN (to Carbide & Carbon Chemicals Corp.). U. S. 1,688,083, Oct. 16. Al butoxide is used as a catalyst in producing olefin alcs. from the corresponding aldehydes, e. g., producing cinnamyl alc. from cinnamyl aldehyde at a temp. of 100° .

Guanidino alcohols. CHEMISCHE FABRIK AUF ACTIEN, VORM. E. SCHERING. Brit. 286,196, Oct. 15, 1926. Guanidino-alcs. are prepd. by treating an amino alc. salt or deriv. with cyanamide, e. g., methylguanidinoethanol-HBr is made by heating methylaminoethanol-HBr with cyanamide in an autoclave for several hrs.

Complex metal alcoholates. HANS MEERWEIN (to Chemische Fabrik auf Actien (vorm. E. Schering)). U. S. 1,689,356, Oct. 30. Alcoholates of different metals such as Mg and Al ethylates or Mg or Al and Na ethylates are caused to react together to form complex alcoholates.

Alkylisopropylenephenols. CHEMISCHE FABRIK AUF ACTIEN (vorm E. Schering). Fr. 636,228, June 18, 1927. Alkylisopropylenephenols are prepd. by heating to between 300 and 310° condensation products of alkylphenols and ketones and distg. E. g., 3-methyl-6-isopropylphenol is obtained from the condensation product of *m*-cresol and acetone, and 4-methyl-6-isopropylenephenol from the condensation product of *p*-cresol and acetone.

Alkylisopropylphenols and their hydrogenation products. CHEMISCHE FABRIK AUF ACTIEN (vorm. E. Schering). Fr. 636,267, June 20, 1927. The alkylisopropylenephenols described in Fr. 636,228 (preceding pat.) are treated with H in the presence of catalysts till 2-8 atoms of H are fixed. Thymol, *p*-thymol, menthol and *p*-menthol are thus obtained.

Naphthisatins. I. G. FARBENIND. A.-G. Brit. 286,358, Dec. 1, 1926. Naphthyl-oxaminic acid halides derived from primary naphthylamines are treated with acid condensing agents such as AlCl₃ or FeCl₃. Several examples are given.

Thiocarbanilide. CARL N. HAND and HAROLD P. ROBERTS (to Rubber Service Laboratories Co.). U. S. 1,688,707, Oct. 23. Aniline and CS₂ are caused to react at a temp. of 46-46.2° in the presence of a small quantity of NH₃. An app. is described.

Hydrolysis of methyl chloride. RALPH H. MCKEE. U. S. 1,688,726, Oct. 23. MeCl mixed with steam is passed at an elevated temp. (suitably about 350-375°) over a hydrolyzing agent comprising Ca(OH)₂ or other alk. earth hydroxide, in order to form MeOH. AmOH may be similarly formed from AmCl.

Phthalic anhydride. FRANK A. CANON and CHESTER E. ANDREWS (to Selden Co.). U. S. 1,689,860, Oct. 30. A mixt. of naphthalene vapor and an O-contg. gas such as air is subjected to the action of a catalyst such as V oxide at a temp. of 400-450° and this temp. is maintained by transmitting the excess heat generated to a compn. of Cd and Hg which will boil at the desired temp.

2-Amino-4-nitro-1-benzoic acid. I. G. FARBENIND. A.-G. Brit. 285,877, Feb. 24, 1927. 2-Amino-, alkylamino-, arylamino- or aralkylamino-4-nitro-1-benzoic acid is made by treating 2-chloro-4-nitro-1-benzoic acid with NH₃, alkylamine, arylamine or aralkylamine in the presence of a catalyst such as finely divided Cu.

Monodiaz compounds of 1,4-diaminoanthraquinone-2-sulfonic acid. GEORG KRÄNZLEIN and FRITZ ROEMER (to Grasselli Dyestuff Corp.). U. S. 1,690,021, Oct. 30. Monodiaz compds. of 1,4-diaminoanthraquinone-2-sulfonic acid compds. are obtained by treating 1,4-diaminoanthraquinone-2-sulfonic acid compds. such as 1,4-diaminoanthraquinone-2-sulfonate (or 2,6- or 2,7-disulfonate), suitably in the form of their Na salts, with NaNO₂ and H₂SO₄.

Styrene. OMAR H. SMITH (to Naugatuck Chemical Co.). U. S. 1,687,903, Oct. 16. A halogen-contg. alkylbenzene such as chloroethylbenzene is heated to a decompn. temp. (which may be about 600-725°) to split off H and halogen and styrene is recovered from the collected liquid reaction products, e. g., by steam distn.

Anthracene condensation products. I. G. FARBENINDUSTRIE AKTIENGESellschaft. Fr. 32,803, Nov. 10, 1926. Addn. to 607,181. Anthranols, oxanthranols, anthrones or their homologs or substitution products are condensed by means of H₂SO₄ without using an oxidizing agent. An example is given of the prepn. of bz-3-methyl-benzanthrone from anthrone and crotonaldehyde.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

The place of biochemistry in medicine. A. GARROD. *Brit. Med. J.* No. 3521, 1099-1101(1928).—An address, mostly historical. J. B. BROWN

The equilibrium of chemical composition in living cells. J. MAURICE JAVILLIER. *Can. Med. Assoc. J.* 19, 1-7(1928).—An address. A. T. CAMERON

The study of the effect of various agents, chiefly sunlight, upon the susceptibility of rachitic rats to infection. ELIZABETH CHANT ROBERTSON. Connaught Lab., Univ.

Toronto. *Can. Med. Assoc. J.* 19, 154-7(1928); cf. *C. A.* 22, 103.—Exposure to the sun for 2 hrs. around noon markedly raises the resistance of young rachitic rats to infection. A. T. CAMERON

The halogen content of animal tissues. A. T. CAMERON AND C. H. A. WALTON. Univ. Manitoba, Winnipeg. *Trans. Roy. Soc. Can.* 22, Sect. V, 1-11(1928).—The results obtained by Magnus Levy (normal man, *C. A.* 4, 1765), Damiens (dog, *C. A.* 15, 1163), Vladesco (cow, *C. A.* 19, 3101) and C. and W. (rat, dog), using different procedures, show relatively comparable figures. No evidence was obtained of the presence of org. Cl in any of the tissues examd. The actual values found for any tissue seem to be largely dependent on the vascularity of such tissue and the amt. of blood and lymph present within it. Values for fresh tissue, rather than for desiccated tissue, should be used for comparison. The av. values for 6 rats were in mg. per 100 g. (fresh tissue 1st, then desiccated tissue), bone, 125, 205; brain, 108, 499; heart, 111, 484; intestinal mucosa, 84, 398; kidneys, 178, 871; liver, 132, 498; lungs, 196, 909; lymph glands, 156, 575; muscle, 60, 233; ovaries, 290, 1126; salivary glands, 125, 523; spleen, 134, 586; stomach mucosa, 136, 626; testes, 222, 1792. Corresponding results for 6 dogs were adrenals, 124, 351; bone, 103, 133; brain, 148, 692; cartilage, 190, 470; duodenal mucosa, 132, 695; heart, 119, 487; kidneys, 251, 1147; liver, 136, 501; lungs, 230, 1009; muscle, 67, 259; ovaries, 190, 750; pancreas, 138, 544; salivary glands, 152, 640; spinal cord, 118, 392; spleen, 171, 726; stomach mucosa, 160, 1119; tendon, 261, 549; testes, 187, 1076; thyroid, 161, 567; uterus, 201, 993. Van Slyke's method was used. Some results for pathol. man are also given. A. T. CAMERON

The action of ultra-violet rays on the skin. ALBERT EIDINOW. *Brit. J. Tuberculosis* 22, 136-9(1928).—The present conception of the action of ultra-violet rays on the skin supports the theory of the production of local photo-biochem. substances which have bactericidal or vitamin properties, local hyperemia of the skin, and stimulation of a leucocytic infiltration of the epidermal tissues. H. J. CORPER

Urease. MARTIN JACOBY. *Fermentforschung* 10, 1-11(1928).—A review, including bibliography of 102 references. A. W. DOX

Comparative studies on the breakdown of casein, serum globulin and serum albumin by dilute alkali, dilute acid, pepsin hydrochloric acid and pancreatic enzymes. EMIL ABDERHALDEN AND WALDEMAR KRÖNER. Univ. Halle. *Fermentforschung* 10, 12-25(1928).—Serum globulin, serum albumin and casein behave somewhat differently when treated for a no. of hrs. with *N* NaOH at 37°. The globulin shows an immediate and rapid increase in amino N; with the albumin this increase is less rapid, and with casein there is a noticeable lag before any increase occurs but the increase eventually exceeds that obtained with either of the other proteins. It is significant that globulin contains glycine while albumin does not, since it was previously shown that polypeptides contg. this amino acid are more susceptible to alkali hydrolysis. With all 3 proteins the hydrolysis is accompanied by a decrease in optical rotation. The cleavage increases also with the temp. and with the alkali concn. Not only polypeptides but also free amino acids are liberated and can be identified by the ester method. Amino and carboxyl groups are set free in equal proportions, but this does not necessarily indicate that they were originally present in acid amide linkage. Treatment with *N* HCl at 37° liberates amino N from albumin but not from globulin or casein. However, an alteration of the last 2 proteins occurs notwithstanding the absence of increase in amino groups. Casein undergoes a partial hydrolysis when treated with pepsin-0.1 *N* HCl, but albumin and globulin are quite resistant. On the other hand, both casein and albumin are hydrolyzed readily by pancreatic ext., while globulin remains unaltered after 30 hrs. and is not hydrolyzed even by trypsin-kinase. A preliminary treatment of globulin with pepsin-HCl, although causing no noticeable cleavage, renders it more susceptible to hydrolysis by *N* NaOH. The HCl evidently plays a part in this reaction by increasing the swelling of the protein, but does not account for the entire effect. The pepsin-HCl treatment renders casein and globulin, but not albumin, capable of further hydrolysis by *N* HCl. Similarly, casein, but not albumin, after digestion with pancreatic ext. undergoes further cleavage when treated with *N* NaOH, but neither one is affected by *N* HCl. All 3 proteins are strongly hydrolyzed by pancreatic ext. if given a preliminary treatment with pepsin-HCl. This is particularly significant in the case of globulin which is not noticeably attacked by either enzyme alone. Pepsin-HCl causes no further cleavage of any of the 3 proteins after pancreatic digestion. After the *N* alkali treatment, pancreatic digestion brings about a further cleavage of globulin but not of casein or albumin. A. W. DOX

The breakdown of *D*- and *L*-alanine and of glycyl-*D*-alanine and *D*-alanylglycine by the organism of the dog. EMIL ABDERHALDEN AND KURT FRANKE. Univ. Halle.

Fermentforschung 10, 39-49(1928).—Enzyme preps. from animal organs have thus given an asymmetric cleavage of racemic dipeptides. It remained to be detd. whether the living organism would show the same selective behavior. A comparison first made of the utilization of *d*- and *l*-alanine by the dog. The amino acid was administered both orally and intraperitoneally. *d*-Alanine gave an increase in total urea N in the urine corresponding approx. to the N of the amino acid administered. There was, however, no increase in amino N, thus indicating that the substance was completely utilized. *l*-Alanine, on the other hand, gave an increase not only in urea N but also in amino N. The increase in urea was much smaller than in *d*-alanine expts. *l*-Alanine was actually recovered from the urine by means of its H_2SO_4 deriv. and by the ester method, but the recovery was not quant. In some cases it seemed probable that the *l*-acid was partially acetylated since a substance responding in properties to acetylalanine was isolated in an impure state, and since amino N content of the urine was greater after than before hydrolysis. The results with *l*-alanine were, however, not uniform. In some expts. the amino N of the urine showed an increase corresponding to 85% of the substance administered and no increase in urea, while in others the increase in urea accounted for 25% of the amino N. Whether the *l*-isomer is in such cases utilized directly, or first rearranged to the *d*-form is not known. Similar feeding expts. with glycyl-*dl*-alanine and with *dl*-alanyl-glycine gave an increase in both amino N and urea. Apparently only a small proportion of the component contg. *l*-alanine is broken down, and it is possible that some interchange occurs in the intestinal tract through the action of bacteria. Glycyl-*l*-alanine was recovered from the urine by converting it into the corresponding anhydride and identified as such. An important observation is the fact that the Pb salts of amino acids (*d*-alanine, *l*-alanine, *d*-valine, *d*-glutamic acid) have a higher optical rotation than the free acids, but in the opposite direction. The Pb salts of dipeptides (*l*-leucyl-glycine, glycyl-*d*-leucine, glycyl-*l*-leucine), on the other hand, show increased rotation in the same direction. This behavior may be useful in distinguishing between amino acids and polypeptides.

A. W. Dox

A parallelism in the behavior of pancreatic secretin and of enterokinase at boiling temperature. I. P. RASENKOV. Obuch Inst. Moscow. *Fermentforschung* 10, 72-78(1928).—Secretin preps. were obtained (1) by introducing 0.5% HCl into an isolated intestinal loop of a dog for 10-5 min., (2) by boiling the mucosa ext. with HCl and neutralizing, and (3) by rinsing with HCl the isolated intestinal loop of a dog on which a Thiry-Vella operation had been performed. When these preps. were adjusted to different degrees of acidity and alk. and then boiled, all showed a complete and quantitative parallelism in the rates at which their secretin and enterokinase activities were destroyed. The possibility is suggested that secretin and enterokinase may be one and the same substance which under certain conditions functions as secretin and under others as enterokinase.

A. W. Dox

Influence of boiling temperature on pancreatic secretin. I. P. RASENKOV. Obuch Inst., Moscow. *Fermentforschung* 10, 78-82(1928); cf. preceding abstr.—The apparent lack of uniformity of secretin in its stability toward boiling in acid or alk. soln. due to the conditions under which the reaction is adjusted. By boiling the prep. in acid soln., or after neutralizing until a ppt. forms, or after adding alkali until the ppt. redissolves, the activity is not destroyed. But if the acid soln. is partially neutralized without formation of a ppt., or if it is so rapidly made alk. as to avoid pptn. boiling alone destroys the activity.

A. W. Dox

The influence of chymosin on the proteins of milk. IV. Enzymes in the stomach contents of calves at different ages. I. ZAYKOVSKII, O. FEDOROVA AND V. IVANKIN. gr. Inst., Leningrad. *Fermentforschung* 10, 83-7(1928); cf. C. A. 20, 3300.—By comparing the rate of fibrin digestion with the rate of milk coagulation, the relative contents of pepsin and chymosin were detd. in exts. of calf stomach at various stages of fetal development and after birth and feeding. Both enzymes are present in the embryo and in approx. const. proportions on the basis of stomach wt. After birth and feeding there is a considerable increase in both enzymes, but the peptic activity increases much more rapidly than the milk-curdling power. Conclusion: Pepsin and chymosin are sep. and distinct enzymes.

A. W. Dox

The question of the occurrence of polypeptides in blood plasma and serum. The use of erepsin and of trypsin-kinase for their detection. EMIL ABDERHALDEN AND ERNST ROSSNER. Univ. Halle. *Fermentforschung* 10, 102-10(1928).—If polypeptides are present in the serum they should be diffusible through a parchment membrane and make their presence known by an increase in amino N when the dialyzate is subjected to the action of erepsin or trypsin-kinase. The amt. of dialyzable N increases

somewhat when the serum is kept for a considerable time, but the possibility of bacterial action could not be definitely excluded, notwithstanding precautions for asepsis. For shorter periods up to 7 days the increase in dialyzable N is so small as to be negligible. In the presence of trypsin-kinase, but not of erepsin, an actual increase does occur. This is probably due to digestion of serum albumin, since the globulin has previously been shown to be resistant to trypsin-kinase. When erepsin or trypsin-kinase is added to the dialyzate obtained from serum no increase in amino N is observed. Evidently no substances are present which are attacked by these enzymes, or else the amt. is extremely small. The dialyzate does, however, show an increase in amino N after acid or alkali hydrolysis, but this may be due to the breaking of other than peptide linkages. No satisfactory evidence was obtained of the presence of polypeptides in serum.

A. W. DOX

Proof of the enzymic nature of the phenomena on which the Abderhalden reaction is based. EMIL ABDERHALDEN AND SEVERIAN BUADZE. Univ. Halle. *Fermentforschung* 10, 111-44(1928).—The Abderhalden reaction, in which the blood serum of pregnant women acts upon placenta protein with formation of dialyzable cleavage products, is definitely shown to be of enzymic nature. When the serum is dried *in vacuo* over H_2SO_4 and P_2O_5 under strictly aseptic conditions and the residue extd. with 87% glycerol, this ext. gives the same reaction. A concd. aq. ext. may be prepd. from dried serum and a positive reaction obtained therewith in cases where the activity of the fresh serum is too slight to be demonstrated by the ordinary procedure. Dried serum has been preserved for one month in sealed tubes without loss of its activity or specificity, while control tests show that a neg. serum does not acquire activity through this treatment. Furthermore, Willstätter's enzyme adsorption method may be applied to the glycerol ext. after diln. with H_2O and adjusting the p_H to 4.7 with acetate buffer. Kaolin and $Al(OH)_3$ thus yield an adsorbate from which the enzyme may again be liberated by elution with $(NH_4)_2HPO_4$. Of the elutions obtained in this manner from gravid sera 76% gave a positive Abderhalden reaction with placenta protein, whereas similar elutions from sera of men and non-pregnant women invariably gave a neg. reaction. The enzymic nature of the Abderhalden reaction was further demonstrated by the fact that the activity of gravid serum and of the eluate prepd. therefrom is destroyed by heating 1 hr. at 60° . By the use of dried preps. it is shown also that cerebrospinal fluid, which was previously thought to have no sp. action on proteins, may give the Abderhalden reaction if a sufficiently concd. ext. is used. In several cases of progressive paralysis positive reactions were obtained between cerebrospinal fluid and brain tissue.

A. W. DOX

Enzymes and biocatalysts in adaptation and inheritance. I. Influence on yeast of preliminary treatment in iron-containing media. HANS V. EULER AND ESTER ERIKSSON. Univ. Stockholm. *Z. physiol. Chem.* 178, 39-51(1928).—Cultivation of yeast in a medium contg. 1 g. $FePO_4$ or 2 g. $FeSO_4$ per l. results in a greatly increased Fe content of the yeast. This represents not only assimilated but also adsorbed Fe. An increase occurs also in the total and especially in the cyclic N, whereas the amino and peptide N show little change. With increasing Fe content the yeast's capacity for decolorizing methylene blue diminishes. Wide variations occur in the compn. of the yeast proteins and in the ratio of protein to nucleic acid according to the treatment accorded even in the absence of Fe. With Fe present a transition from aliphatic N to porphyrin derivs. contg. pyrrole rings is probable. In this process the porphyrin derivs. would tend to form Fe complexes and on the other hand the Fe would tend to stimulate porphyrin formation. With increasing Fe content the O consumption by the yeast diminishes. If it is assumed that the respiration pigment is an Fe complex, then it would appear that some other substance which also functions in the respiration process is destroyed or inactivated by the excess Fe. At any rate this is an instance in which an alteration in biol. activity is brought about by varying the chem. compn. Further study of this phenomenon may afford exptl. evidence as to whether dominance of a character can be traced to the quant. distribution of the corresponding gene substance, and thus throw some light on problems in genetics.

A. W. DOX

The solubility of cystine in urine. GUNNAR BLIX. Univ. Uppsala. *Z. physiol. Chem.* 178, 109-24(1928).—Although 1 l. of H_2O at room temp. dissolves only 0.1 g. cystine, the same vol. of urine can contain 5 times as much cystine in soln. The possible factors considered in attempting to account for this increased soly. are p_H , mineral constituents, diffusible org. constituents, and colloids. The min. soly. of cystine in H_2O is at p_H 3. At p_H 6 the increase in soly. is negligible, at p_H 6.5 it is 10%, at p_H 7 it is 15-20% and from there on the soly. increases rapidly up to 1300-1400% at p_H 9. However, the p_H of urine rarely exceeds 7.5; hence it is a comparatively unimportant

factor. Of greater importance is the influence of mineral constituents. In 0.25 *N* solns. of the various salts present in urine the increased soly. of cystine varied from 11% with NH_4Cl to 59% with CaCl_2 . In a soln. cong. the same salts in the same concns. as in urine the soly. of cystine was 0.149 and 0.143 g per l. The org. constituents of urine, viz., urea, creatinine and glucose, had no influence on the soly. The urinary colloids, e. g., dialyzed urine, dissolved 0.149 and 0.144 g. cystine per l. as compared with 0.078 g. per l. H_2O at the same temp. and p_{H} . There seems to be no true soly. equil. since more cystine remains in the urine after adding a solid in NaOH than can be dissolved by shaking with solid cystine. The colloids evidently stop the crystn. of cystine before an equil. can be established. A. W. Dox

Further studies on yeast amylase. ALFRED GOTTSCHALK. Städtisches Krankenhaus, Stettin. *Z. physiol. Chem.* 178, 139-47(1928); cf. *C. A.* 20, 3018.—The fermentation of glycogen by yeast which has become impoverished in cozymase by long storage is less complete than that of glucose under the same conditions. Glycogen thus requires more cozymase for its fermentation than does glucose. The extent of the fermentation depends also on the concn. of glycogen. With an abundance of cozymase supplied by addn. of boiled yeast ext., a 2% soln. of glycogen is fermented to a little more than half the extent of the parallel fermentation of 2% glucose. The difference is very much smaller with 1% solns. The induction period of glycogen fermentation is considerably longer, probably because of the complex process of glycogen saccharification which precedes the fermentation. The addn. of boiled ext. not only supplies the addnl. requirement of cozymase but also furnishes an activator which facilitates the glycogen saccharification by the yeast amylase. Glycogen is more completely fermented after treatment with Taka-diastrase than after treatment with salivary or yeast amylase. The initial fermentation velocity is in this case almost equal to that of glucose. Yeast does not contain an excess of amylase adsorptively bound to the structural constituents of the cell as is the case with frog liver, since plasmolysis, grinding with quartz sand or treatment with adrenaline gives no increase in autolytic fermentation. A. W. Dox

The preparation of a substance which participates in the enzymic breakdown of glucose to lactic acid (Meyerhof's activator). EDVARD BRUNICUS AND STIG PROFFER. Univ. Stockholm. *Z. physiol. Chem.* 178, 164-8(1928).—In prepg. Meyerhof's activator (MX) from a top yeast it was found that no activator could be obtained unless glucose was added during the autolysis. The following procedure gave an active product: Suspend 500 g. yeast in 500 cc. H_2O , add 10 g. glucose and allow the mixt. to stand 1 hr. at 30-5°. Add 10 g. glucose and some PhMe and centrifuge after 36 hrs. autolysis at 30-5°. Ppt. the clear yellow soln. with an equal vol. 96% EtOH , suspend the ppt. in H_2O and remove the undissolved matter by centrifuging. In the presence of this activator a dried muscle prepn., to which has been added phosphate buffer of p_{H} 7.0 and cozymase, converts glucose into lactic acid. Bottom brewery yeast, on the other hand, yielded an activator by the same treatment without addn. of glucose during the autolysis. This is probably because the bottom yeast itself contains sufficient carbohydrate while the top yeast does not. By subjecting the activator soln. to dialysis through collodion its activity was somewhat increased, probably by removal of inactive material. A. W. Dox

The distribution of creatinephosphoric acid in various muscles and organs of the animal organism. D. FERDMANN AND O. FEINSCHMIDT. Biochem. Inst. Charkow. *Z. physiol. Chem.* 178, 173-8(1928).—Detns. of creatinephosphoric acid in white muscle (*M. biceps femoris*), in red muscle (*M. semitendinosus*), and in the mixed type (*M. adductor longus*) of rabbits, also in the white breast muscles and red leg muscles of roosters showed that the greatest amt. is present in white and the least in red muscle. In white muscle it comprises about 30% of the total creatine, while in red muscle the proportion is much less. The smooth muscles of the viscera also contain creatinephosphoric acid but only in small quantity as compared to the voluntary muscles. It was found in pigeon stomach and heart, rooster stomach, heart and testes, rabbit heart, spleen and uterus, but not in rabbit or rooster kidney. In general the muscles with the highest lactacidogen content run highest in creatinephosphoric acid and it is probable that a relationship exists between the metabolism of these 2 substances. A. W. D.

The creatinephosphoric acid, creatine and lactacidogen content of white and red muscles. ALEXANDER PALLADIN AND S. EPELBAUM. Biochem. Inst. Charkow. *Z. physiol. Chem.* 178, 179-85(1928).—Creatinephosphoric acid detns. on the biceps femoris, the semitendinosus and the heart muscles of the guinea pig confirm the findings of Ferdmann and Feinschmidt (cf. preceding abstr.) with respect to the variation between white, red and smooth muscle of rabbits and roosters, and in the parallelism

between creatinephosphoric acid and lactacidogen content. White muscles are capable of more rapid contraction, and their content of creatinephosphoric acid as well as of lactacidogen evidently contributes to their greater capacity for quick performance.

A. W. DOX

Studies on porphyrin. A. A. HYMANS V. D. BERGH AND A. J. HYMAN. *Dcut. med. Wochschr.* 54, 1492-4(1928).—A discussion of recent work on the clinical and physiological significance of porphyrin.

ARTHUR GROLLMAN

A comparison of the titration curves of coagulated and uncoagulated egg albumin. B. M. HENDRIX AND VELMA WILSON. Univ. of Texas. *J. Biol. Chem.* 79, 389-403 (1928).—Uncoagulated egg albumin combined with more 0.01 N acid or base in the range pH 2.8 to 7.7 than an equal wt. of coagulated albumin. The unfiltered coagulated albumin showed a greater combining power than the dried material. It is, therefore, suggested that heat coagulation involves a decrease in the free $COOH$ and NH_2 groups in the protein mol.

ARTHUR GROLLMAN

The time of absorption and excretion of boric acid in man. LOUIS KAHLENBERG AND N. BARWASSER. Univ. of Wisconsin. *J. Biol. Chem.* 79, 405-8(1928).—Fifty seconds after the immersion of the feet in satd. boric acid, the latter could be detected in the urine.

ARTHUR GROLLMAN

The oxidation of disulfide acids in the animal organism. BEULAH D. WESTERMAN AND WM. C. ROSE. Univ. of Ill. *J. Biol. Chem.* 79, 423-8(1928).—Although dithiodiglycollic acid, β -dithiodipropionic acid and α -dihydroxy- β -dithiodipropionic acid cannot replace cystine for the growth of rats, these compds. are readily oxidized when administered orally or subcutaneously to rabbits.

ARTHUR GROLLMAN

Crystalline urease. III. Variations in jack-bean meal as affecting the yield of crystals. JAMES B. SUMNER AND RACHEL G. HOLLOWAY. Cornell Univ., Ithaca. *J. Biol. Chem.* 79, 489-92(1928).—Minor changes are introduced for prepg. cryst. urease as described in C. A. 22, 1989. Certain samples of jackbean meal were encountered whose urease was only partly sol. in 31.6% acetone and in 30% alc.

ARTHUR GROLLMAN

Determination of the tyrosine content of proteins. MILTON T. HANKE. Univ. of Chicago. *J. Biol. Chem.* 79, 587-609(1928).—The low results previously reported (C. A. 20, 1090) by H. for the tyrosine content of proteins is attributed to the inclusion of this material in the histidine fraction obtained by pptn. with Ag_2O . Tyrosine was quantitatively pptd. from a crude protein hydrolyzate as *tyrosino-HgCl₂*. The tyrosine content of a given protein was varied and hence the figures quoted are not considered as an accurate index of their compn.

ARTHUR GROLLMAN

Hexose phosphates and alcoholic fermentation. ALBERT L. RAYMOND AND P. A. LEVENE. Rockefeller Inst. *J. Biol. Chem.* 79, 621-35(1928).—The effect of a no. of phospho esters on the induction period of glucose with zymn was detd. The hexose diphosphate was most potent in abolishing the induction and this property could not be removed by repeated recrystns. of the ester as the strychnine salt. The rate of hydrolysis of the esters during the induction period exceeded the CO_2 production observed when the induction period was removed with added diphosphate. Rate of hydrolysis and hence of fermentation was dependent upon the configuration of the ester. Addn. of arsenate or increased concn. increased the fermentation rate of the Neuberg, Robison and Harden esters. Addn. of arsenate produced but little increase in the rate of hydrolysis or fermentation of the synthetic esters.

A. G.

Cozymase. Its relation to phosphatase activity. ALBERT L. RAYMOND. Rockefeller Inst. *J. Biol. Chem.* 79, 637-48(1928).—The removal of cozymase from zymn decreased the hydrolysis of hexose diphosphate both in the presence and absence of arsenate. This effect was one of complement enzyme action since neither washed zymn nor cozymase produced dephosphorylation of hexose diphosphate while the mixt. of the two was active in this respect. Cozymase was extd. in large amts. from live yeast by H_2O when toluene was added.

ARTHUR GROLLMAN

Effect of Röntgen radiation on solutions of tyrosine and cystine. WILHELM STENSTRÖM AND ANNE LOHMANN. Univ. of Minnesota. *J. Biol. Chem.* 79, 673-8 (1928).—Tyrosine in weak aq. soln. is changed as regards its phenol group when exposed to x-rays. The amt. changed is proportional to the radiation absorbed. About 0.01 mg. of tyrosine in a 0.002% soln. is changed by 186 kg. Röntgens. Cystine was unaffected by the rays.

ARTHUR GROLLMAN

Oxidation-reduction systems of biological significance. I. The reduction potential of cysteine: its measurement and significance. L. MICHAELIS AND LOUIS B. FLEXNER. Johns Hopkins Univ. *J. Biol. Chem.* 79, 689-722(1928).—A soln. of cysteine in absence of O established a definite potential at indifferent blank Pt, gold-plated Pt,

and Hg electrodes. The potential, reproducible within 0.005 v., was independent of the cystine concn. and was a logarithmic function of the cysteine and H-ion concns. Slight traces of O displaced the potential to the pos. side. Hg was less sensitive to O than the Pt electrodes and gave final values in a relatively short time. The anaerobic potential was neg. enough to account for reduction of all indicator dyes by cells under anaerobic conditions. The potential E , referred to the normal H electrode, could be expressed by the relation $E = -0.001 - RT/F \ln [\text{cysteine}] + RT/F \ln [\text{H}^+]$. Methods for prepg. and testing O-free N are described. ARTHUR GROLLMAN

Hemocyanin. V. The oxygen dissociation curve of hemocyanin from the snail (*Helix pomatia*) in dialyzed solution. ELLEN STEDMAN AND EDGAR STEDMAN. Dept. of Medical Chemistry, Univ. of Edinburgh. *Biochem. J.* 22, 889-901(1928); cf. *C. A.* 21, 3064.—No change in the O dissocn. curve with change in p_{H} was observed. The combination between hemocyanin and O takes place thus: $\text{Hcy} + \text{O}_2 = \text{HcyO}_2$. Each mol. of hemocyanin contains 2 atoms of Cu. BENJAMIN HARROW

Action of carbon monoxide on the autoxidation of sulfhydryl compounds. MALCOLM DIXON. Biochem. Lab., Cambridge. *Biochem. J.* 22, 902-3(1928).—CO has no effect on the rate of the autoxidation of cysteine or reduced glutathione induced by the addn. of Fe or Cu salts or by freshly dissolved hematin. Upon standing hematin breaks down into a mixt. of simpler Fe compds. This mixt. has the same catalytic power as the original hematin, but now CO markedly inhibits the reaction. B. H.

Action of ultra-violet rays on complement. JOHN GORDON AND ARTHUR WORMALL. Dept. Physiology, Univ. Leeds. *Biochem. J.* 22, 909-19(1928).—Ultra-violet rays destroy the complement of guinea-pig serum. This is due to the inactivation of the heat-labile protein components. The heat-stable components are more resistive. Irradiation of guinea pigs does not increase the complement activity of the serum. BENJAMIN HARROW

Creatine-creatinine equilibrium. The apparent dissociation constants of creatine and creatinine. ROBERT KEITH CANNAN AND AGNES SHORE. Dept. Biochemistry, University College, London. *Biochem. J.* 22, 920-9(1928).—Detns. of the apparent dissocn. const. of creatinine at 15°, 25° and 30° and of the first dissocn. const. of creatine at 17°, 25° and 30°, have been made. The velocity consts. of the reversible system creatinine-creatinine have been detd. at 30° over the p_{H} range 2 to 10, and have been related to $[\text{H}^+]$, the dissocn. consts. of the reactants and certain empirical consts. BENJAMIN HARROW

Tyramine oxidase. I. A new enzyme system in liver. MARY LILLIAS CHRISTIAN HARE. Biochem. Lab., Cambridge. *Biochem. J.* 22, 968-79(1928).—Exts. of liver oxidize tyramine, 1 atom of O being used for 1 mol. of tyramine. Deamination also occurs with oxidation. 0.002 M KCN does not affect the oxidation. H_2O_2 is produced during the reaction. The optimum p_{H} for this liver enzyme is 10.0. It is destroyed at p_{H} 11.5 and is inactivated, but not destroyed, at p_{H} 4.4. Tyrosine is not attached and the enzyme produces no pigment. Phenylethylamine is also oxidized. B. H.

Uricase and its action. I. Preparation. STANISLAUS J. PRZYLECKI. Univ. Warsaw. *Biochem. J.* 22, 1026-34(1928).—The enzyme (from the glycerol ext.) was purified by pptn. with acetone, alc. or NH_4 sulfate or by dialysis. B. H.

Pancreatic extracts in relation to lactic acid formation in muscle. EDWIN M. CASE AND DOUGLAS R. MCCULLAGH. Biochem. Lab., Cambridge. *Biochem. J.* 22, 1060-70(1928).—The pancreatic factor which inhibits lactic acid production by muscle enzymes is amylase. BENJAMIN HARROW

Isolation of pure L-proline. BERNARD WM. TOWN. Imperial College of Science and Technology, London. *Biochem. J.* 22, 1083-6(1928).—The Cu salts of protein hydrolysis are sepd. into 3 fractions; the fraction sol. in CH_3OH contains the proline, which can be sepd. as a picrate. BENJAMIN HARROW

Effect of arsenic upon some oxidation-reduction systems. GERALDINE BARRY, ELIZABETH BUNBURY AND ERNEST L. KENNAWAY. Cancer Hospital Research Inst., London. *Biochem. J.* 22, 1102-11(1928).—Arsenites retard the oxidation-reduction systems of (a) hypoxanthine and xanthine oxidases; (b) AcH and colloidal Pt.; and (3) AcH , glycolol and phosphate. Arsenates are inactive. BENJAMIN HARROW

Liberation from yeast of substances giving the nitroprusside reaction. YVONNE POURBAIX AND ERNEST L. KENNAWAY. Cancer Hospital Research Institute, London. *Biochem. J.* 22, 1112-27(1928).—The factors producing the nitroprusside test are one of 2 classes; in the one class the liberation is chiefly intracellular; in the other it is extracellular also. Many of the pos. agents are known to be hemolytic. B. H.

Effect of fluorides and iodides on the clotting of milk by pepsin. WINFRED MARY CLIFFORD. King's Coll. for Women, London. *Biochem. J.* 22, 1128-32(1928);

cf. *C. A.* 21, 3064.—The clotting of milk is inhibited by the addn. of fluorides of Na, K, and NH₄ and the iodides of Li, Na, K and NH₄. BENJAMIN HARROW

Iodine values of some sterols by Dam's method. ALICE MARY COPPING. University Coll., London. *Biochem. J.* 22, 1142-4(1928).—Ergosterol by Dam's method (*C. A.* 19, 3280) shows a high I value. A low I value is obtained in the presence of a ketonic group in the mol. BENJAMIN HARROW

A review of recent work on micro-dissection and micro-injection of living protoplasm. JOAN LATTER. *J. Roy. Micros. Soc.* [3], 48, 300-13(1928).—Some 30 references are given to work since 1924, together with brief summaries of each investigation.

C. W. MASON

The action of nascent hydrochloric acid gas on tricalcium phosphate and other insoluble salts. D. LO MONACO. *Arch. sci. biol.* (Italy) 12, 605-9(1928).—The author's method of converting insol. phosphates into sol. phosphates by passing a current of Cl gas into a mixt. of ground tricalcium phosphate and wet org. matter (hay, straw, sawdust) has been extended to the study of other insol. salts. Fe phosphate and leucite yield sol. phosphates and silicates with formation of the corresponding chlorides when treated by this method. This behavior led the author to study the formation of HCl in the dog's stomach on the assumption that nascent Cl is formed which reacts instantaneously with H to form HCl. He was unable to prove this directly *in vivo*. If, however, a mixt. of insol. phosphates and hydrocarbons is added to the gastric juice of a dog and placed in an incubator at 37° the amt. of monocalcium phosphate formed is almost 2-3 times that formed by the simple addn. of HCl equal in quantity to that of the gastric juice.

PETER MASUCCI

The analysis of the curve of respiratory exchange of minced tissues as a function of p_H . M. COMEL. *Boll. soc. ital. biol. sper.* 3, 550-3(1928).—The respiratory exchange (y) of tissue pulp may be expressed: $y = f(p_H)$. By plotting y against p_H , $y = 0$ at p_H 5.3. If $x = p_H$ at 5.3 a curve may be constructed showing the absorption of O₂ which is approx. represented by the equation: $y = ax + bx^2 + cx^3 + dx^4$, in which a and c are pos. and b and d are neg. A mathematical analysis of the curve is given in detail showing values for $x_1 = 1.92$, $x_2 = 0.44$, $x_3 = 0.80$, $x_4 = 1.6$, $x_5 = 0.67$. Tissue pulp suspended in buffered solns. of varying p_H shows a high respiratory exchange at p_H close to neutrality; the O₂ absorbed diminishes as a function of p_H , becoming zero near the isoelec. point.

PETER MASUCCI

Colloids and crystalloids of urine as factors influencing the solubility of uric acid. R. ASCOLI. *Boll. soc. ital. biol. sper.* 3, 547-9(1928).—Expts. were made to det. whether the colloidal substances in urine favored the soly. of uric acid. Dialyzed urine dissolved less uric acid than undialyzed urine; the dialyzate favored the soly. of uric acid almost as much as the whole urine. Conclusion: The solvent action of urine for uric acid must be attributed to crystalloids and not the colloids in the urine. P. M.

Combined peptic-tryptic digestion in vitro. A. RONCATO. *Boll. soc. ital. biol. sper.* 3, 558-61(1928).—The action of pepsin and that of trypsin were studied on the same substratum—corn meal, corn bread, soy bean flour with and without defatting, raw bean flour, cooked bean flour and lean flesh. The action of trypsin alone on these substrata was also studied. After the action of pepsin, tryptic digestion is regular whether the protein is vegetable or animal, cooked or uncooked. The final proteolysis depends upon the degree of hydrolysis by peptic action. Uncooked vegetable proteins resist tryptic digestion if not preceded by peptic action. Tryptic digestion not preceded by peptic digestion yields a digestate which is quantitatively and qualitatively different from that obtained by peptic-tryptic digestion. Soy bean flour defatted by benzene vapors at 100-110° does not denature the proteins and render them indigestible.

PETER MASUCCI

Nephelometric studies on enzymic proteolysis. VII. Effect of ions on the stability of trypsin. P. RONA AND H. KLEINMANN. *Pathol. Inst. Charité, Universität Berlin. Biochem. Z.* 196, 177-96(1928); cf. *C. A.* 20, 3303; 22, 792.—The effect of electrolytes on the stability of aq. trypsin solns. has been investigated within a p_H range of 5 to 6. NaCl in a 2 *N* concn. has about the same stabilizing effect as Na₂SO₄. MgCl₂ and MgSO₄ have a stabilizing effect in concns. of 0.1 to 0.02 *N*, while Al₂(SO₄)₃ is effective in a 0.01 *N* concn. The stabilization is therefore attributed to cations, and the higher the valence the less the concn. required to insure stability. The action of the cations is generally the same as that of the H ion. The addn. of cations is unfavorable at the H-ion concn. (p_H 1.7) corresponding to the opt. stability. The instability of unpurified trypsin solns. is thus attributed to its cation content. Likewise, the injurious action on trypsin of boiled stomach juice is attributed to the electrolyte content.

S. MORGULIS

Studies on the enzymic proteolysis. P. RONA AND E. MISLOWITZER. Pathol. Inst. Charité, Universität Berlin. *Biochem. Z.* 196, 197-222(1928).—Although casein is easily adsorbable it is not or very nearly not adsorbed by a collodion membrane. On the contrary, hydrolyzed casein is adsorbed. The adsorption on the collodion membrane indicates a fragmentation of the casein mol. If the increase in adsorbability is correlated to the increase in the amino acid N it appears that the fragmentation of the casein by the enzyme does not involve dissolution of the CONH grouping. S. M.

Ultra-violet illumination of cells in relation to the cancer problem. A. AND L. GURVICH. Histol. Inst., Univ., Moscow. *Biochem. Z.* 196, 257-75(1928). S. M.

Is sea water a physiologically balanced solution for isolated organs of warm-blooded animals? S. V. ZIGANOV. Pharm. Lab., Medizinisches Staatsinstitut, Odessa. *Biochem. Z.* 196, 333-9(1928).—Water from the Black Sea, warmed to body temp., can be injected in amts. of 40 cc. per kg. into warm-blooded animals without causing injury. It may serve to replace part of the blood in cases of poisoning or following hemorrhage. It can, therefore, be regarded as physiologically balanced when made isotonic by proper diln. The heart of warm-blooded animals can be preserved for a long time in this sea water, but it cannot sustain its work. S. MORGULIS

Permeability of surviving animal membranes. R. AMMON. Städtische Krankenanstalt, Mannheim. *Biochem. Z.* 196, 441-64(1928).—Killed animal membranes are 3-5.5 times more permeable to glucose than live membranes. The diffusion consts. for sep. membranes are very small as compared to the consts. for glucose and water. Expts. with insulin permit no definite explanation as to its effect on the permeability of surviving membranes or its effect on the oxidation of glucose. S. MORGULIS

The absorption of bromine by casein as well as casein and keratin hydrolyzates. FRITZ LIEBEN AND ROBERT MÜLLER. Physiol. Inst., Univ. Wien. *Biochem. Z.* 197, 119-35(1928).—When casein is treated with very large excesses of Br₂, either free or in alk. soln., compds. are formed contg. 5-6% Br₂. No stoichiometric relationship is apparent and an adsorption on the casein mol. surface must be assumed. In protein hydrolyzates the amt. of Br₂ found is dependent upon the tyrosine, histidine and cystine. Tyrosine absorbs 4 atoms Br₂, histidine 4, cystine 10 per mol though these quantities are modified by various factors such as amt. of excess, length of action, etc. Histidine which has reacted with Br₂ is no longer precipitable by phosphotungstic acid and appears quantitatively in the filtrate. S. MORGULIS

Effect of illumination on the proteins of the eye lens. FRITZ LIEBEN AND PETER KRONFELD. Physiol. Inst., Univ. Wien. *Biochem. Z.* 197, 136-40(1928).—A loss of tryptophan in the proteins of the pigs lens which was exposed to diffuse daylight in the presence of rose-bengal or in the absence of this to a quartz lamp was not demonstrated. Normal and cataract lenses from human subjects show no difference in the tryptophan content of their proteins. It is said that the high protein content of the lens protects it from loss of the tryptophan. S. MORGULIS

The complement of amylase. VI. HANS PRINGSHEIM, JONAS BONDI AND EDUARD THILO. Chem. Inst., Univ., Berlin. *Biochem. Z.* 197, 143-51(1928). Tryptic digestion of protein is a necessary condition to convert it into an energetic activator of amylase. S. MORGULIS

Physico-chemical studies on radiated proteins. IV. Influence of short wave radiations on the absorption capacity of serum and serum proteins in the ultra-violet. MONA SPIEGEL-ADOLF. Physiol. Inst., Univ. Wien. *Biochem. Z.* 197, 197-209(1928).—The increased absorption capacity of radiated serum albumin is not due in large measure to the atm. O₂. Likewise radiated pseudoglobulin shows such an increase which, however, is not found in euglobulin. S. MORGULIS

Metaphosphatase. TORAO KITASATO. Kaiser Wilhelm-Inst. Biologie, Berlin-Dahlem. *Biochem. Z.* 197, 257-8(1928).—Liver and kidney of rabbits, and yeast can convert enzymically metaphosphate to orthophosphate, but their action is weaker than that of Taka-phosphatase. S. MORGULIS

The effectiveness of alkaloids and the degree of their dissociation in buffered solutions as a function of the hydrogen-ion concentration of the medium. SEIBUN MAYEDA. Inst. für Schiffs- und Tropenkrankheiten, Hamburg. *Biochem. Z.* 197, 410-17(1928).—The dissocn. degree of a hydrolyzable salt is detd. as a function of the p_H of the medium. The degree of dissocn. of a salt of strong acid and a weak base with a dissocn. const. of K_b is given by the equation $\gamma_b = K_b/K_a + K_b[H^+]$. With the aid of this equation it was shown for the quinine alkaloid that the dependence of the biological effect on the p_H is entirely a matter of the alkaloid base set free through hydrolytic dissocn.; that the biological action is due only to the free base; and that the effect on living microorganisms represents an adsorption process. S. MORGULIS

Salt hydrolysis of starch. E. GLIMM AND R. GRIMM. Lab. Nahrungsmittelchemie and landwirtschaftliche Gewerbe, Tech. Hochschule, Danzig. *Biochem. Z.* 197, 445-59(1928).—Expts. in which the attempt was made to hydrolyze starch with salt solns., amino acid or peptone solns. were unsuccessful, hydrolysis occurring only very rarely. Under strictly sterile conditions no hydrolysis took place. From peptone (Witte) a species of sarcina was isolated together with an unknown pediococcus which hydrolyzes starch to dextrin. S. MORGULIS

Further studies on the stereochemical specificity of the lipases. P. RONA AND R. STELSOHN-SCHRECHTER. Pathol. Inst., Univ. Berlin. *Biochem. Z.* 197, 482-90 (1928).—A study of the hydrolysis of *d*- and *l*-mandelic acid and of its esters by esterase from pig liver and pancreatic lipase. S. MORGULIS

The composition of the non-protein carbon and non-protein nitrogen compounds, especially the oxyproteic acids of the blood. OTTO DEUTSCHBERGER. Physiol. Inst., Univ. Wien. *Biochem. Z.* 198, 268-95(1928).—The non-protein C was detd. by the wet combustion method. In 100 cc. horse blood 182.5 mg. C were found, which agrees with Stepp's results for human blood. The same protein-free blood contains 96 mg. glucose, 16.4 mg. lactic acid, 23.5 mg. urea, 7.5 mg. creatine and creatinine and 11 mg. amino acid. The oxyproteic acids were isolated as Ba salts from blood deproteinized with phosphotungstic acid. The Ba salts are insol. in alc. The C, H and N of this baryta fraction, obtained from 3 samples of 2 l. each of defibrinated horse blood, contained 66 mg. C, 8 mg. H and 19 mg. N per 100 cc. blood. The non-protein N of the same blood was 44 mg. Thus, 43% of the non-protein N and 36% of the C belongs to the oxyproteic acid fraction, which gives an at. relationship: $C_{100}H_{144}N_{24}$. This baryta fraction from the blood like that from the urine gives Ehrlich's diazo and Weiss' urochromogen reaction. The 44 mg. of non-protein N of 100 cc. of horse blood are made up of 19 mg. oxyproteic acid N; 11 mg. amino acid N; 11 mg. urea N and 3 mg. creatine-creatinine N. This accounts fully for all the nitrogenous compds. Of the total non-protein C in 100 cc. horse blood 165.6 mg. C are accounted for in the compn. given above. The total non-protein C, however, directly detd. is 182.5 mg. This leads to the conclusion that a small quantity of some unknown C compd. is probable. S. M.

Studies on the physiological and pathological chemistry of the brain. II. The phosphatides of the petroleum ether fraction from normal human brains. KARL SINGER AND OTTO DEUTSCHBERGER. Physiol. Inst., Univ. Wien. *Biochem. Z.* 198, 328-39 (1928); cf. *C. A.* 21, 2306.—The total amt. of the petroleum ether fraction per 1 g. fresh brain is const. for normal persons. The compn., however, varied in different sections of the brain. The N partition in the petroleum ether fraction is the same in the human and horse brain; only the galactoside N is decidedly lower. The fetal and infant brains contain small quantities of petroleum ether extractives, but the N content is $1\frac{1}{2}$ -2 times as great as in adult brains. In the course of development the petroleum ether fraction increases and its N decreases. In the first 3 years this fraction increases rapidly in the next 3 years more slowly and only in the third decade reaches a const. value. S. MORGULIS

The general occurrence of gold in food stuffs and organs. RAGNAR BERG. I. innere Abteilung des Stadtkrankenhauses Freidrichstadt, Dresden. *Biochem. Z.* 198, 424-7(1928).—In expts. on the Pb in various org. substances it was found that the CuS formed in the pptn. with H_2S does not go fully in soln. in HCl after heating but leaves a black residue. This residue was discovered to be Au. This observation has led to an examn. of a variety of org. materials, both vegetable and animal, with the result that appreciable amts. of Au were found in nearly all of them. In cows' brain as much as 1.4 mg. Au per 100 g. dry substance is present. S. MORGULIS

Studies on the reaction of tissues. A. B. CARLSTRÖM, R. EGE AND V. HENRIQUES. Physiologisches Lab., Universität, Kopenhagen. *Biochem. Z.* 198, 442-62(1928).—A colorimetric method for detg. the reaction of tissues is described. This has a systematic error because of the protein, for which, however, a correction has been worked out. Studies of the postmortem reaction change due to lactic acid occurs only in muscle tissue but not in the tissue ext. Even at 0° lactic acid is formed and influences the reaction of ground muscle tissue. The lactic acid production is much more rapid when the muscle has been previously treated with liquid air. The buffering value of rabbit muscle for the shift from p_H 7 to 6 is equal to 0.055 mol. acid, corresponding to 525 mg. lactic acid per 100 g. The temp. correction for the muscle p_H is 0.007 p_H per degree rise in temp. In resting muscle at 37° the p_H = 6.80-6.95, or even 7.0 when formation of lactic acid is prevented. The p_H of muscle tissue absolutely free from lactic acid is calcd. as 7.1. During activity the reaction shifts toward the acid side, even as low as p_H = 6.34, while in a condition of rigor to p_H = 5.90. The much higher H-

ion concn. of even resting muscle as compared with that of the blood is attributed to a Donnan equil. S. MORGULIS

Studies on the reducing power of fructose in the Bertrand procedure. BÉLA RÓHNÉ. Physiol.-chem. Inst. kgl. ungar. Univ. Budapest. *Biochem. Z.* 199, 53-9 (1928).—The reducing power of hydrolyzed sucrose and lactose is practically the same, and both are the same as that of glucose. However, although pure fructose is equiv. to glucose, galactose has only 95% of the reducing capacity of glucose. These results show that in the presence of glucose both fructose and galactose reduce as if they were glucose. S. MORGULIS

Studies on the new enzyme glucoseoxidase. I. D. MÖLLER. Pflanzenphysiol. Lab., Univ. Kopenhagen. *Biochem. Z.* 199, 136-70 (1928).—Definite strains of *Aspergillus niger* and *Penicillium glaucum* were cultured on a special nutritive medium. 100 g. dry mold are rubbed with 100 g. pure sand and 35 g. kieselguhr, and pressed under 300 atms., yielding 35-50 cc. press juice. This is poured into 12 vols. of either 96% alc., alc. + ether mixt. or acetone; the ppt. is at once filtered off and dehydrated with abs. alc., then dried over H_2SO_4 in a vacuum. From 100 cc. press juice 3-6 g. of dry prepn. is obtained. Studies of the O_2 consumption and acid production in a glucose soln. in the presence of this enzyme prepn. show that the enzyme catalyzes the oxidation of glucose to acid which does not reduce Fehling's soln. This catalyzer is an enzyme because it is specific in action, depends upon proper H-ion concn. and is destroyed at about 73°. From the quant. results showing that 11.5 cc. O_2 is taken up for each 1 cc. N acid formed and each 0.18 g. glucose disappearing it is concluded that this acid is probably gluconic, $C_6H_{12}O_7$. By isolation and analysis it was actually demonstrated that at least 20% of the acid produced under the influence of the glucose-oxidase is gluconic acid. The acid is not pptd. by neutral Pb acetate; therefore it is concluded that all the acid formed in this reaction must be *d*-gluconic acid. S. M.

Contribution to the study of the oxidative destruction of glucose. III. B. BLEYER AND W. BRAUN. Tech. Hochschule, München. *Biochem. Z.* 199, 186-94 (1928); cf. C. A. 21, 2462.—Oxidation of glucose with chloramine proceeds over pyruvic acid to AcOH and finally CO_2 , which is similar to the fermentative changes. But in fermentation the first alteration of the glucose is the formation of the biologically active γ -glucose with a low rotation, the esterification with H_3PO_4 and finally the hydrolysis of methylglyoxal. It is very certain that these preliminary steps in the fermentative oxidation of glucose are the action of the OH ions in the chloramine oxidation. The next step is the oxidation of the triose to pyruvic acid. In fermentation this is ascribable to a special enzyme, but in the oxidation expt., it is the specific effect of the chloramine, other oxidative agents having another influence. The OH ions so essential in the preliminary process of hydrolysis are of no use in the further reactions, and in fact are detrimental insofar as they promote the transformation of methylglyoxal into a difficultly oxidizable hydrate, lactic acid. The third step in the reaction is the splitting of the pyruvic action into AcH and CO_2 with subsequent oxidation of the former to AcOH. The splitting off of CO_2 from keto acids is a normal occurrence in all biological oxidation processes. Chloramine, therefore, shows analogies to the biological oxidants. Willstätter and Schudel found that glucose is oxidized to gluconic acid by an alk. soln. of I_2 . This, of course, would contain NaOI just as the chloramine soln. unquestionably contains NaOCl. It might be expected from this that the two reactions would show similarities. In the oxidation by alk. I_2 , however, the reaction stops at gluconic acid. But if the concn. of OH ions or of I_2 is increased the reaction proceeds further. It is, therefore, concluded that in the oxidation by chloramine likewise the first product is the gluconic acid. S. MORGULIS

Biochemical splitting of sugar according to the second form of fermentation under the influence of carbaminic acid hydrazide and thiocarbaminic hydrazide. Isolation of acetaldehyde and glycerol. MARIA KOBEL AND ALEXANDER TYCHOWSKI. Kaiser Wilhelm-Inst. Biochemie, Berlin-Dahlem. *Biochem. Z.* 199, 218-29 (1928).—The acid hydrazides combine easily with AcH, and they can be employed in order to promote the second form of fermentation. Glycerol appears in quantities corresponding to the amt. of formed aldehyde. S. MORGULIS

Comments on the preceding paper and on our earlier contribution to the fixation of methylglyoxal in alcoholic fermentation. CARL NEUBERG AND MARIA KOBEL. Kaiser Wilhelm-Inst. Biochemie, Berlin-Dahlem. *Biochem. Z.* 199, 230-1 (1928). S. MORGULIS

The hemolysis effect of radiated ergosterol and cholesterol. R. FISCHER. Pharmakol. Inst., Univ. Innsbruck. *Biochem. Z.* 199, 294-7 (1928).—The products formed

when ergosterol and cholesterol are exposed to the action of sunlight or to ultra-violet radiation have a hemolytic effect.

S. MORGULIS

Studies of the chemical properties of secretin substances in food stuffs. A. BICKEL AND A. KORCHOW. *Pathol. Inst., Univ. Berlin. Biochem. Z.* 199, 434-44 (1928).—Subcutaneous injection of the original Maggi bouillon cubes, or of its carnitine fraction or of the carnosine fractions I and II, (isolated by the same method as is used in meat ext. analysis) produces a distinct secretoexcitatory effect on the mucous membrane of fundus in Pavlov's stomach pouch, and the same results were found after oral administration.

S. MORGULIS

Albumin-metal salts. H. BECHHOLD. *Inst. für Kolloidforschung, Frankfurt-a.-M. Biochem. Z.* 199, 451-8(1928).—When a soln. of electrolyte-free albumin is mixed with heavy metal salts it is found that with the very low salt concn. (0.0001 *N*) there is formed a ppt. which, however, disappears on further addn. of salt; then, when the concn. becomes still greater a new ppt. is formed. If a mixt. of albumin and earthy alk. soln. (BaCl_2 , SrCl_2 , CaCl_2) is subjected to ultrafiltration with washing, all the salt soln. passes into the ultrafiltrate and the washed albumin is salt-free, so that apparently the protein-salt complex breaks up in the washing process. This holds also for salts of Ni or Co. The behavior is different with the chlorides of Zn, Al, Cr and Fe, and in this case the washed protein contains both anions and cations. With the first 3 a const. relationship was found of 1 g.-equiv. of cation for each 5100-5200 g. albumin. The situation was different for Fe salts. The *Liquor ferri albuminati* is a well-known pharmacopeal prepn. with 0.175% Fe and about 6% albumin. This soln. is in reality a very fine dispersion (possibly, a mol.) of Fe hydrosol in albumin. This shows distinctly different behavior from the plain Fe hydrosol. Thus, neither is pptd. at the p_H corresponding to that of the gastric contents (1.2-2.0) but at the p_H of the small intestine, corresponding to 0.02-0.04% Na_2CO_3 , the colloidal Fe ppts. while the albumin Fe soln. is unchanged. It is not possible to prep. *Liquor ferri albuminati* by mixing directly colloidal $\text{Fe}(\text{OH})_3$ and albumin. The Ag and Au albumin combinations are also important. The former furnish the therapeutically non-irritant disinfectants, while the latter is being made use of in demonstrating the presence of particles of submicron size and of microorganisms. This is brought about by the deposition of AuCl_3 on the surface which is fixed and cannot be washed out in the ultrafilter. On subsequent ignition Au skeletons are left behind.

S. MORGULIS

Equilibria between albumin and metal salts (silver nitrate, ferric chloride, gold chloride). ERICH HEYMAN AND FRIEDRICH OPPENHEIMER. *Inst. Kolloidforschung, Frankfurt-a.-M. Biochem. Z.* 199, 468-97(1928).—A method is described for the purification of protein by electroultrafiltration. The combination of highly purified isoelec. albumin with AgNO_3 , FeCl_3 and HAuCl_4 was studied for various proportions of the salt and protein by detg. the uncombined salt in the intermicellar space. For analysis only a small portion of this intermicellar fluid was obtained by ultrafiltration so that the equil. conditions of the system were not disturbed. The max. quantity of combined AgNO_3 and FeCl_3 is almost independent of the abs. concn. of albumin and salt; but more FeCl_3 is found (8.5×10^{-4} g.-equiv. per g. albumin) than of AgNO_3 (4.5×10^{-4} g.-equiv.). The theory of the nature of the albumin salt combination is discussed and it is pointed out that an assumption of an adsorption phenomenon is not incompatible with the facts though the view of Pauli and Pfeiffer of combination through extra valencies is accepted. It is suggested that the AgNO_3 -albumin compd. may

have this formula: $\left[\text{Alb} \begin{matrix} \text{(NH}_3\text{)}_n \\ \text{(COOH)}_n \end{matrix} \right] \begin{matrix} (\text{NO}_3)_m \\ \text{Ag}_m \end{matrix}$ which is analogous with the type of albumin- FeCl_3 compd. where the proportions are high. On the contrary, in mixt. with a low FeCl_3 concn. the mol. is supposed to correspond to $\left[x\text{Fe}(\text{OH})_3 \cdot \right.$

$\left. \text{Alb} \begin{matrix} \text{(NH}_3\text{)}_n \\ \text{(COOH)}_n \end{matrix} \right] \begin{matrix} \text{Cl}_3(m-x) \\ \text{Fe}_{(m-x)} \end{matrix}$. The combination with AuCl_3 is believed to be of the type as that of the FeCl_3 .

S. MORGULIS

Further studies on the extent of action of phosphatase. CARL NEUBERG AND RT P. JACOBSON. *Kaiser Wilhelm-Inst. Biochemie, Berlin-Dahlem. Biochem.* 498-517(1928).—It was shown that the di-potassium salt of the diphenyl ester pyrophosphoric acid, $\text{K}_2(\text{C}_6\text{H}_5)_2\text{P}_2\text{O}_7$, is hydrolyzable by phosphatase, and this is true for the inorg. $\text{K}_2\text{P}_2\text{O}_7$ which is hydrolyzed to an orthophosphate by muscle

pulp; lastly even NaPO_3 is changed by an enzyme in Takadiastase, yeast or animal organs to orthophosphate, which is thus the end product of enzymic hydrolysis of all 3 types of phosphoric acid. The following compds.: monomethyl- and trimethyl-phosphate, phosphoric acid ester of methylpropylcarbinol and cetylmonophosphate; borneol-phosphate and cholesterol-monophosphate; also di-*o*-cresol-pyrophosphoric ester, di-*m*-cresol-pyrophosphate ester and di- α -naphthol-pyrophosphate ester were all hydrolyzable by the phosphatase enzyme. Trimethyl- and triphenyl-phosphates are the only compds. which so far failed to be hydrolyzed by phosphatase. S. M.

The presence of lipase in polymorphonuclear leucocytes. WALTER FLEISCHMANN. Physiol. Inst., Univ. Wien. *Biochem. Z.* 200, 25-8(1928).—In polymorphonuclear leucocytes obtained from the sterile peritoneal exudate in rabbits the presence of lipase could be demonstrated by the manometric procedure of Rona-Lasnitzki. S. M.

An activator of malt amylase. S. NISHIMURA. Lab. of Kawaguchi-Machi Brewery, Tokyo. *Biochem. Z.* 200, 81-9(1928).—The malt amylase complex is not made up of 2 enzymes but of the enzyme amylase and another substance which has the ability to promote the liquefaction and hydrolysis of starch. The enzyme amylase by itself hydrolyzes the starch but very slowly, this effect being greatly stimulated by the activator the same as trypsin is by enterokinase. The activator loses its effect at p_H 3.0 and is reactivated at p_H 7.4. The idea that there are 2 enzymes, a starch-splitting and a saccharifying enzyme, the former being slightly injured at 70° , the latter on the contrary being completely destroyed, is false. At 70° the enzyme amylase is much inactivated while the activator component is still fairly intact. S. MORGULIS

Urine colloids and crystalloids as solvents for uric acid. RUGGERO ASCOLI. Inst. allgem. Pathol., Kgl. Univ. Mailand. *Biochem. Z.* 200, 95-107(1928).—Removing the colloids from urine either by shaking with benzene or through ultra-filtration has no effect on the soly. of the uric acid. Further expts., however, showed that complete urine is a perfect uric acid solvent because when it is satd. with warm uric acid it prevents its pptn. on cooling. Dialyzed urine is scarcely a solvent for uric acid, but the dialyzate possesses definite and perfect solvent power. The reaction of the dialyzed portion is not the essential factor since there may be acid urines with good, and alk. urines with poor, solvent properties. It is not denied that the urinary reaction is important but the presence of substances with a uric acid stabilizing action is even more essential. Conclusion: The crystalloid substances have the uric acid solvent effect while the urine colloids are of no importance in this respect. S. MORGULIS

Effect of ultra-violet rays on the passing out of pigment in the blood of normal and splenectomized dogs. G. FARKAS AND H. TANGL. Physiol. Inst., Univ. Budapest. *Biochem. Z.* 200, 184-9(1928).—Ultra-violet radiation inhibits the passing out of the blood pigment in normal dogs. In splenectomized dogs this effect does not appear because the inhibition due to the operation is apparently already maximal. S. M.

Biochemical studies on the equilibrium of halogen ions. I. The combination of egg albumin with halogen ions. KINSHIRO ITO. Inst. Anatomy, Kyoto Medical College. *J. Biochem. (Japan)*, 9, 17-43(1928).—The halogen-ion activity in KCl, NaCl, LiCl, NaBr or NaI measured with the Ag halide electrode was shown to diminish through the addn. of egg albumin, this effect being attributed to the adsorption of the halogen ions. S. MORGULIS

Biochemical studies on uric acid. TOKUSABURO SHIMODA. Biochem. Dept. Jikei-Kwai Med. Coll., Tokyo. *J. Biochem. (Japan)* 9, 117-85(1928).—Uric acid dissolved in 0.01 *N* NaOH (20 mg. per 100 cc.) is completely destroyed within 14 days at room temp. ($18-20^\circ$). The uric acid on oxidation yielded urea and NH_3 , but allantoin could not be demonstrated. The total amt. of N before and after the destruction did not differ materially. The velocity of the destruction of uric acid in alk. soln. was parallel to the concn. of the alk. soln. In neutral or acid solns. there was no evidence of destruction even at 37° and within 72 hrs. O_2 hastened the uric acid destruction in alk. soln. while N_2 delayed the process. The velocity of the destruction increased progressively with rising temp. and was inversely proportional to the uric acid concn. Uric acid seemed to be protected from destruction by adsorption. The blood intestinal contents and various organ exts. have been tested but only liver exts. promoted greatly the destruction of uric acid in soln. while the duodenal contents had a slight stimulating effect. The results with organ exts. from various animals (dog, cat, guinea pig, rat, rabbit) were practically the same. The opt. p_H for the destruction of uric acid by the liver ext. was 7.3. The uric acid introduced *per os* into rabbits is practically all absorbed by the alimentary tract, and is excreted in the urine chiefly as urea and NH_3 , only a small fraction appearing as uric acid. The destruction of intravenously injected uric acid proceeds in the rabbit in the liver alone and not in any other organ. S. M.

The significance of iron in biological oxidation. I. The role of ferrous salts as aldehydase. KUNIO ANDO. Biochem. Lab., Aichi Med. Coll. *J. Biochem. (Japan)* 9, 187-99(1928).—Exptl. evidence is presented of the many similarities in the action of Schardinger's enzyme and of ferrous salts. It is thought that possibly some org. Fe compd. is really the Schardinger enzyme. In the kinetics of reduction of FeSO_4 it is assumed that the splitting of the H_2O mol. is the first step. There is thus activation of the H which becomes attached to the aldehyde. It is supposed that the enzyme, like the FeSO_4 , attacks the H_2O mol. near it, and transfers the activated H to the acceptor and the O to the donator. His view differs from that of Wieland that the oxidation of the donator is initiated by the activation of the H followed by its transfer to a reduceable substance, in the assumption of the direct action of activated O on the donator with the resulting oxidation or reduction depending on the chem. constitution of the donator. This view, however, also differs from Warburg's regarding O activation by Fe catalysis in that it assumes that the O of the H_2O mol. is activated as a result of the H activation for which the atm. O_2 serves as acceptor. These views are based on expts. with the methylene blue technic which shows that inorg. ferrous salts act as aldehydases. Various colloidal substances, such as protein or lipids, promote the discoloration, which is not inhibited by KCN in less than 0.05 M concn. On the contrary, HgCl_2 has been found to be very toxic. The temp. coeff. of the reaction is 1.86. II. The role of ferrous salts as oxido-reductases for various organic substances. *Ibid* 201-14.—The oxido-reductase activity of ferrous salts towards a variety of org. substances is described. Org. substances which are also easily oxidized *in vivo* proved to be good donators for ferrous salts or for the methylene blue system. Lecithin and the higher fatty acids are extremely powerful accelerators. The view is developed of the surface action in these reactions.

S. MORGULIS

Hemolysis and glucolysis. KATSUMASA NOSHI. II. Med. Klinik, Med. Akad., Osaka. *J. Biochem.* 9, 243-9(1928).—An erythrocyte ext., obtained by ether hemolysis and completely freed from microscopic structures, still possesses distinct hemolytic power in a phosphate mixt. whereas in a citrate medium no appreciable glucolytic activity could be found.

S. MORGULIS

The significance of some auxosubstances in the urease reaction. MATSUNOSUKE KITAGAWA. Biochem. Lab., Kyushu Imperial Univ. *J. Biochem. (Japan)* 9, 347-52(1928).—Urease free from auxosubstance never loses its activity provided the inhibitor is in some way removed from the system. However, the pressure of inhibitor substance from any source and even in mere traces as may be found in the distd. water or in the urea causes a diminution of activity by formation of an inactive compd. If an auxosubstance is added it combines, forming an undissociable compd. with the inhibitor and sets free active urease. Therefore the urease activity is detd. by the relative amt. of auxosubstance and inhibitor in the reaction system.

S. MORGULIS

The effect of the addition of protein on the surface tension of a sodium glycocholate solution. RYUZO SUGINO. Biochem. Inst., Tokyo Imperial Univ. *J. Biochem. (Japan)* 9, 353-81(1928).—The influence of a protein on the surface tension of a glycocholate soln. depends upon the pH . Only at H-ion concns. of the soln. where the protein exists as the cation does it affect the surface activity of the glycocholate soln. probably through some combination of the protein and glycocholic acid. This combination has been found to be stoichiometric. Further, an explanation is offered of the mechanism whereby the addn. of the protein to a very weak glycocholate soln. increases the surface tension while the addn. to a more concd. soln. causes a diminution of the surface tension.

S. MORGULIS

The effect of proteolytic enzymes on the benzoyl and phthalyl derivatives of polypeptides. I. The action of intestinal erepsin and of yeast protease on phthalylglycylglycine and phthalylidiglycylglycine. SENJI URZINO. Med. chem. Inst., K. Univ., Tokyo. *J. Biochem. (Japan)* 9, 453-63(1928).—Intestinal erepsin hydrolyzes phthalylidiglycylglycine but not phthalylglycylglycine, but both are more or less split by yeast protease. II. The action of tissue proteases on the benzoyl- and phthalylglycylglycine. *Ibid* 465-81.—Neither beef muscle press juice nor rabbit muscle maceration juice has any effect on benzoylglycylglycine and phthalylglycylglycine. Rabbit liver pulp or maceration juice and pig liver press juice do not hydrolyze these dipeptides. Maceration juice hydrolyzes considerably glycylglycine and leucylglycine. Pig kidney maceration juice can hydrolyze benzoylglycine, benzoylglycylglycine and glycylglycine. The digestion mixt. with benzoylglycylglycine contained benzoic acid. With phthalylglycylglycine or phthalylglycine no evidence was found of hydrolysis. III. The action of pancreatic proteases on benzoyl- and phthalylglycylglycine. *Ibid* 483-97.—Pancreatin, pig pancreas pulp, pancreas press juice and glycerol exts. of dry pancreas preps.

definitely hydrolyze benzoyl- and phthalylglycylglycine. By activating the pancreas preps. much more extensive hydrolysis was obtained. Further expts. show that the trypsin fraction which definitely hydrolyzes edestin but not glycylglycine attacks the benzoyl and phthalylglycylglycine. S. MORGULIS

Effect of some alkaloids on an alcoholic extract of pepsin-fibrin peptone. M. A. RAKUZIN AND T. A. GENKE. Central State Sci.-Tech. Inst., Leningrad. *Zhurnal expl. Biol. Med.* 9, 221-3(1928).—Strychnine, brucine, quinine, codeine, morphine and theobromine behave like the amphoteric $Al(OH)_3$, which takes up only certain fragments of the protein in an alc. ext. of proteins. An alc. ext. of pepsin-fibrin peptone gives the same reaction after the addn. of an alc. soln. of these alkaloids as before, except the Millon reaction, showing that the tyrosine has been removed by the alkaloids. This suggests that the alkaloid acts the same way as enzymes and can also be compared to toxins. In fact the conclusion is drawn that alkaloids are cryst. toxins. Furthermore, some alkaloids with a mol. wt. above a certain limit are actually in colloidal state. S. MORGULIS

The characterization of the proteins of blood, muscles and internal organs of healthy rabbits and chickens by means of color reactions. M. A. RAKUZIN AND T. A. GENKE. Central State Sci.-Tech. Inst., Leningrad. *Zhurnal expl. Biol. Med.* 9, 225-9(1928).—The biuret, Millon, Liebermann, Adamekiewitz, xanthoproteic, Molisch and Pettenkofer reactions were carried out on the alc. extrn. of various organs and blood of rabbits and chickens. The Ostromyslensky reaction for free NH_2 groups is given in few instances and is very weak; the Liebermann, Molisch and Pettenkofer reactions were absent. S. MORGULIS

The effect of x-rays on the process of enzyme formation in the isolated cells of the pancreas. A. I. BOGAYEVSKII AND B. GOLDSTEIN. Med. Inst. Kiev. *Zhurnal expl. Biol. Med.* 9, 328-34(1928).—Through the action of x-rays on the perfused pancreas a greater concn. of amylase and lipase was found in the fluid. The effect is really one of stimulation of the gland cells, as it is possible to cause also a diminution of activity by further increase of the dose. Prolonged action of the x-rays can produce a depressing effect which however passes off. S. MORGULIS

Oxidase in the blood leucocytes and the stability of the enzyme in various types of leucocytes. J. B. GOLDMAN. Dept. Gen. Pathol., N. C. Univ., Rostov a. D. *Zhurnal expl. Biol. Med.* 9, 552-8(1928).—The α -naphthol-Li-toluidine blue staining method of Epstein was used. All myelocytes and monocytes are pos. for oxidase. "Stammzellen" of the myeloid group only gradually develop the oxidase granules. Basophiles are generally oxidase neg. Atypical monocytes are similar to neutrophile leucocytes as regards the oxidase, and some monocytes do not show the oxidase because of the instability of the enzyme complex. The stability of the enzyme under the influence of heat, sunlight, etc., is greatest in eosinophiles, least in monocytes, while it is intermediate in the neutrophiles; x-rays acting directly on the blood preps. have no effect. The greatest enzyme stability of the eosinophiles corresponds to their greatest viability. S. MORGULIS

Thermostability and regeneration of inactivated enzymes. V. KULIKOV AND M. BOBKON. Microbiol. Inst. Narkomzdrav, Moscow. *Zhurnal expl. Biol. Med.* 10, 147-52(1928).—If the heat inactivation of enzymes is assocd. with a coagulation of other substances present in the mixt. the enzyme must become adsorbed on the coagulated particles and its regeneration is probably a slow elution process. In proteolytic enzymes the regeneration takes place only when the inactivation is carried out at a pH 7.9. At more acid or alk. pH the inactivation is either irreversible or the inactivation is not complete. S. MORGULIS

Changes in the activity of the intestinal juice enzymes depending upon the kind of food. I. Amylolytic enzyme. S. V. ANDREYEV AND S. I. GEORGIEVSKII. Inst. pathol. Physiol. I State Univ., Moscow. *Zhurnal expl. Biol. Med.* 10, 169-79(1928).—The amylolytic action of the intestinal juice varies according to the content of starch in the food. Thus it is greatly increased on a milk-bread diet, diminishes with a reduction of the carbohydrates and is least on a meat diet. S. MORGULIS

Non-cystine sulfur of proteins. G. BARGER AND F. P. COYNE. Univ. Edinburgh. *Arch. sci. biol. (Italy)* 12, 141-4(1928).—Ergothioneine occurs in ergot and in mammalian blood corpuscles. It contains a S deriv. which Berger and Ewins showed to be a thiol-betaine of histidine (cf. C. A. 6, 1154). Attempts to synthesize thiobistidine and related compds. are described. L. W. RIGGS

The carotiproteins, protein pigments derived from the carotinoides in animals. J. VERNE. *Arch. sci. biol. (Italy)* 12, 203-10(1928).—A review with 23 references to the literature is given. L. W. RIGGS

Terms used in radiology. HENRY K. PANCOAST, GIOACCHINO FAILLA AND W. WARNER WATKINS. **J. Am. Med. Assoc.* 91, 960-1(1928).—The recommendations of the Subcommittee on Nomenclature of the Section on Radiology of the Am. Med. Assoc. are reported in 18 paragraphs. Sensible reasons are given for the retention or discard of terms in use. A general adoption of the recommendations of this comm. would avoid much confusion. L. W. RIGGS

Radiated vitamin B and automatin action. H. ZWAARDEMAKER. *Proc. Acad. Sci. Amsterdam* 31, 258-60(1928); cf. *C. A.* 21, 3059, 3389, 3628.—An eel's heart arrested by deprival of K resumes its beats through the addn. of the automatin derived from another radiated heart after a latency of 3.5 hrs. The frequency augments gradually and reaches a max. in 15 min. This pulsation continues for 16 hrs. The effect of non-radiated vitamin is to produce sep. beats with no quick rhythm. After the test-heart has been latent for 1 hr., the addn. to the circulation of radiated vitamin B causes intense contractions which reach a max. in 20 min. The regular beats continue 13 hrs. The pulsations engendered by automatin are similar to those caused by radiated vitamin B. The latency depends on the time required for the preceding washing out of K and automatin. The frequency depends on the concn. of the stimulating substance whether this be automatin or radiated vitamin B. The duration of radiation should not be less than 4 hrs. and preferably should be over 12 hrs L. W. RIGGS

Similarity between physicochemical and biological reactions. C. P. SIDERIS. Assoc. of Hawaiian Pineapple Cannerys, Honolulu, Hawaii. *Plant Physiology* 3, 79-83(1928).—Two proteins (designated A and B) were isolated from the stem of the pineapple. Protein A has an isoelec. point at p_H 6.4 and protein B at p_H 4.8. Protein A was used in the present study. The protein purified by dialysis was further dild. with distd. water and after thorough stirring, 100 cc. was distributed into a no. of Erlenmeyer flasks. To each of these flasks different vols. of either 0.1 N HNO_3 or NaOH were added, giving a range of p_H 2.63-11.05. Aliquot portions of these solns. were innoculated with the spores and mycelium of *Fusarium martii*, *Verticillium* sp., *Penicillium* sp., and the cultures incubated at 27°. None of these organisms was able to grow in isoelec. protein A. *Fusarium* grew in solns. of this protein having a p_H value above that of the isoelec. point of the protein; but *Verticillium* grew only in solns. of the protein having p_H values below that of the isoelec. point, and *Penicillium* sp. grew in solns. of the protein having p_H values either above or below the isoelec. point. The probable operative mechanism of the enzymes effective in making the proteins available is discussed. It is suggested that the condition of the protein at the isoelec. point, and above or below this point, is: At isoelec. point, $HOOC - R - NH_2 + H^+ \rightarrow (HOOC - R - NH_2)^+$. Above the isoelec. point, $HOOC - R - NH_2 + OH^- \rightarrow (OOC - R - NH_2)^- + H_2O$. WALTER THOMAS

Lipides and their estimation in vegetable tissues. CHARLES E. SANDO. Bur. of Plant Ind., Washington, D. C. *Plant Physiology* 3, 155-84(1928).—The numerous classifications of the fats and "fat-like" compds. are listed in detail under each authority's name. S. urges that in accordance with the recommendations of the Comm. on the Reform of the Nomenclature of Biological Chemistry (*C. A.* 17, 3433; 19, 3278) that the term "lipides" and not "lipoids" or "lipins" be used as the generic term for those plant and animal substances that are insol. in water but sol. in fat solvents such as ether, alc., chloroform and benzene and are, either actually or potentially, related to the fatty acids as esters and that yield fatty acids on hydrolysis. S. suggests that considerable confusion would be avoided if Bloor's scheme (*C. A.* 19, 3278) of classification were adopted. The importance of the solvent in the estn. and extn. of lipides from vegetable tissues is pointed out and general data dealing with the common fat solvents together with a table of phys. constants are given. Three methods for the detn. of lipids are given in detail and critically examd.: (1) official method of the Assocn. of Official Agr. Chemists (*A. O. A. C. Methods of Analysis*, 1925), (2) the modified Koch method (*C. A.* 4, 1756), (3) the Kumagawa-Suto method (*C. A.* 2, 2560; 19, 3278). WALTER THOMAS

The proteins of Indian foodstuffs. II. The proteins of ragi. Eleusin, the alcohol-soluble protein (NARAYANA, NORRIS) 12. The constitution of the bile acids. XIV. The condensation of dehydrocholic acid with itself and with aromatic aldehydes (BORSCHKE, FESKE) 10.

Practical considerations in the selection of blood-sugar methods for clinical use in diabetes. I. M. RABINOWITCH. General Hospital, Montreal. *Can. Med. Assoc. J.* 19, 49-51(1928).—R. considers that for routine clinical work the picric acid method is ideal. A. T. CAMERON

Detection of veronal, adaline and bromural in urine. E. A. VAN RIJN. Univ. Amsterdam. *Pharm. Weekblad* 65, 1030-2(1928).—To 100 cc. of urine in a tall cylinder add 10 cc. 0.5 N Pb(OAc)₂, allow the ppt. to settle and then filter. Shake twice with 2 vols. of Et₂O, adding a little EtOH if an emulsion forms. Filter the Et₂O layer through a dry filter and evap. in a glass dish. Dissolve the residue in 10 cc. boiling H₂O, add 5 cc. dil. H₂SO₄, boil and add 0.1 N KMnO₄ until a permanent pink color appears. Boil again, cool and treat with H₂O₂ to reduce the MnO₂ and excess KMnO₄. Heat to boiling, shake the warm soln. twice with 2 vols. Et₂O, filter the Et₂O ext., evap. in a glass dish and dry 24 hrs. in a vacuum desiccator. The residue of veronal gives the correct m. p. With bromural, Me₂CHCHBrCONHCONH₂, and adaline, Et₂CBBrCONHCO-NH₂, recrystn. from boiling H₂O is necessary before the correct m. p. is obtained. Veronal does not react with Nessler reagent, bromural gives a yellow to dirty green ppt., and adaline gives a brown ppt. A. W. DOX

Creatinephosphoric acid and its determination. D. FERDMANN. Biochem. Inst. Charkow. *Z. physiol. Chem.* 178, 52-61(1928).—In traumatic injury of muscle an extraordinarily rapid cleavage of the creatinephosphoric acid occurs. This enzymic cleavage can be suppressed by quickly making alk. while the muscle is being comminuted. By grinding the muscle in a mortar with quartz sand in the presence of Na₂B₄O₇ of pH 9.15 the detn. of creatinephosphoric acid is made possible. The method then consists in the colorimetric detn. of H₂PO₄ before and after acidifying the alk. ext. For the synthesis of lactacidogen *in vitro* at the expense of the inorg. H₂PO₄ in the muscle pulp the presence of creatinephosphoric acid is not absolutely necessary. A. W. D.

New contrivances for the respirometer. SVEN STEFFENBURG. Univ. Stockholm. *Z. physiol. Chem.* 178, 75-80(1928).—For measurement of fermentation velocity by yeast it is preferable to read gas vol. at const. pressure rather than gas pressure at const. vol. as in the Barcroft manometer. The app. devised for this purpose consists of a respiration chamber or reaction vessel connected by a capillary tube bearing a 3-way stopcock to a capillary gas buret graduated in cu. mm. The gas in the buret is adjusted to atm. pressure by a leveling bulb. The respiration chamber, which is immersed in a thermostat, may be agitated by a motor-driven shaking device attached to the capillary connection, the buret remaining stationary so that the reading can be taken during the shaking. A. W. DOX

Rapid methods for the chemical analysis of the gastro-duodenal contents and the differential diagnosis between hemorrhagic ulcer duodeni and ventriculi. MOSES EINHORN. *Deut. med. Wochschr.* 54, 1379-80(1928).—The gastro-duodenal contents are tested with Töpfer's soln., phenolphthalein, blue litmus, benzidine and H₂O₂, and HNO₃. The findings permit of a differential diagnosis. A. G.

The basic amino acids of horse hemoglobin. HUBERT B. VICKEY AND CHARLES S. LEAVENWORTH. Conn. Agr. Expt. Sta., New Haven. *J. Biol. Chem.* 79, 377-88 (1928).—Analysis of the basic amino acids of horse hemoglobin by direct isolation methods showed histidine 7.64%, arginine 3.32%, and lysine 8.10%. These results are in agreement with the assumption that the hemoglobin mol., weighing 66,800, consists of 33 mols. histidine, 13 of arginine, and 37 of lysine. The Ag compd. of histidine was best sepd. from arginine at pH 7.4. Complete seps. were only effected by repeated pptns. and the N contents of the different fractions could not be relied upon to give a measure of the proportions of base in them. The wts. of the dinitronaphtholsulfonates gave the best evidence regarding the actual compn. of the histidine and arginine fractions, and the wt. of the picrate regarding the lysine fraction. Practically complete pptn. of histidine from a relatively pure soln. was obtained by using Hopkin's reagent. ARTHUR GROLLMAN

A colorimetric method for the determination of inorganic phosphate in blood serum. S. L. LEIBOFF. Lebanon Hospital, N. Y. *J. Biol. Chem.* 79, 611-19(1928); cf. following abstr.—A method is described for detg. the inorg. P of blood serum. After deproteinization with trichloroacetic acid, the filtrate is alkalinized with NH₄OH, reacidified with AcOH and the P pptd. with UO₂AcO. The ppt. is dissolved in trichloroacetic acid, converted into (UO₂)₂Fe(CN)₆ and compared colorimetrically with a similar soln. contg. a known amt. of P. ARTHUR GROLLMAN

A colorimetric microdetermination of phosphate. K. HINSBERG AND K. LANG. Chem. Lab. med. Univ. Klinik, Freiburg i. Br. *Biochem. Z.* 196, 465-70(1928); cf. preceding abstr.—The principle of the method depends upon the quant. pptn. of inorg. phosphates by U acetate in an AcOH medium and in the presence of an NH_4 salt: $\text{H}_2\text{PO}_4 + \text{UO}_2(\text{CH}_3\text{COO})_2 + \text{CH}_3\text{COO.NH}_4 = 3\text{CH}_3\text{COOH} + \text{UO}_2\text{NH}_4\text{PO}_4$. An excess of $\text{UO}_2(\text{COOCH}_3)_2$ is added and the excess detd. colorimetrically by the addn. of $\text{K}_4\text{Fe}(\text{CN})_6$. The following solns. are needed: (1) 0.01 N $\text{UO}_2(\text{CH}_3\text{COO})_2$, contg. 2.1215 g. of the salt in a l., (2) 0.5% $\text{K}_4\text{Fe}(\text{CN})_6$ soln. and (3) a soln. contg. 105 g. $\text{NH}_4\text{COO.CH}_3$ and 100 cc. glacial acetic acid in a l. Procedure: to 2 cc. protein-free urine (dild. 1:10 previously) are added 2 cc. of the $\text{UO}_2(\text{COOCH}_3)_2$ soln., 1 cc. of the acetate mixt. and made up to 10 cc. with H_2O . The ppt. is centrifuged off and 5 cc. of the clear supernatant fluid is transferred to a test tube contg. 2 cc. of the $\text{K}_4\text{Fe}(\text{CN})_6$ soln. and after 30 min. the color is compared with that of a blank run exactly as before except that the urine is omitted. Example of calcn.: reading of blank 10.0, that of unknown 13.77. Excess of $\text{UO}_2(\text{COOCH}_3)_2$ present is obtained thus: $4.2430 \text{ mg.} \times 10/13.77 = 3.0814 \text{ mg.}$ Therefore, $1.1616 \text{ mg. UO}_2(\text{COOCH}_3)_2$ used in pptn. of P. $1.1616 \times 0.073 = 0.0848 \text{ mg. P,}$ or $1.1616 \times 0.167 = 0.194 \text{ mg. P}_2\text{O}_5$, or $1.1616 \times 0.224 = 0.2602 \text{ mg. PO}_4$.

S. MORGULIS

Blood-sugar determination and separation of sugars with live yeast. ALBERT L. RAYMOND AND J. G. BLANCO. Rockefeller Inst. *J. Biol. Chem.* 79, 649-55(1928).—The observations of Somogyi (*C. A.* 21, 752) on the adsorption of glucose and non-adsorption of unfermentable sugars by yeast cells were confirmed. A technic is described using 0.3 cc. blood or aq. soln. Dihydroxyacetone, xylose, ribose, arabinose, galactose, lactose and maltose in aq. soln. were recovered quantitatively in the filtrate after yeast treatment. Fructose, mannose and sucrose were partially adsorbed. Glucose was quantitatively adsorbed at concns. of 500 mg. per 100 cc. Maltose was adsorbed to the extent of 40% in the presence of blood. The action of the yeast is selective, only glucose being removed when mixed with sugars of the non-adsorbed group.

ARTHUR GROLLMAN

Sugar metabolism. Lactose, galactose and xylose. J. G. BLANCO. Rockefeller Inst. *J. Biol. Chem.* 79, 667-72(1928).—The method of Somogyi (*C. A.* 21, 752) was applied to the detn. of lactose, galactose and xylose in the blood after their administration to rabbits, orally, subcutaneously and intravenously. The results differ from those obtained by Corley (*C. A.* 21, 763, 2921, 3958) using fermentation methods.

ARTHUR GROLLMAN

Characterization of very small quantities of proteins by Van Slyke's method. NUGGIBALLI NARAYANA AND MOTHNAHALLI SREENIVASAYA. Indian Institute of Science, Bangalore. *Biochem. J.* 22, 1135-7(1928).—An extension of Thimann's method (*C. A.* 21, 2486) for the detn. of Hausmann nos. in small quantities of proteins. B. H.

Micro-determinations of lead (a contribution to the diagnosis of lead poisoning). A. SEISER, A. NECKE AND H. MÜLLER. *Arch. Hyg.* 99, 158-64(1928).—The dried material from blood, feces, or urine is first decompd. with HNO_3 and H_2SO_4 . The soln. is neutralized with NH_3 ; with blood the pptn. of FeCl_3 serves as indicator; with urine and feces, *p*-nitrophenol is used. The mixt. is made just alk., and satd. with H_2S . The ppt. is removed by filtration through asbestos, and then the Fe and Mn are sepd. from the Pb by treatment with a mixt. contg. 50% alc. and 3% H_2SO_4 , satd. with H_2S . Traces of Cu are removed by 3% KCN. The residue is extd. with hot dil. HNO_3 and the soln. evapd. to dryness on the water bath; this extn. is repeated with Pb acetate soln. The solid residue is taken up with water and neutralized with very dil. alkali; 2 cc. satd. boric acid is added, and 0.5-1 cc. NaOCl soln., contg. 15% active Cl; and the mixt. warmed to 90-95° for 2 hrs. The mixt. is cooled and filtered; the Pb is treated with crystals of tetramethyldiaminodiphenylmethane and glacial AcOH ; and filtered. The blue color of the filtrate is proportional to the Pb content, and may be compared colorimetrically with a standard Pb soln. of approx. the same concn. Analysis of the blood of normal persons shows a variation in Pb content from 0 to 0.02 mg. per 100 cc. Higher concns. than 0.02 mg. suggest Pb poisoning from some source. The concns. found in the blood of patients with Pb poisoning varied from 0.06 to 0.17 mg. in 100 cc. blood; from 0.65 to 3.6 mg. in 100 g. dried feces; and from 0.05 to 0.17 mg. in 1 l. urine.

P. Y. JACKSON

Determination of urobilinogen in feces and urine by means of a new extraction method. A. ADLER AND M. BRESSER. *Deut. Arch. klin. Med.* 155, 326-41(1927).—That the extraction method previously described gives exact quant. results is shown by the following expt.: to 30 cc. colorless urine was added 1.4 mg. mesobilirubinogen dissolved in 20 cc. alc.; 0.2 mg. MnSO_4 and 0.5 cc. glacial HAcO was added, and the

mixt. extd. with CHCl_3 for 6 hrs. 1.3 mg. was recovered and detd. colorimetrically. Normally about 1 mg. urobilinogen is eliminated daily in the urine, and about 100 mg. in the feces. In hemolytic icterus values as high as 35 mg. (urine) and 4600 mg. (feces) were detd.; in anemia, leucemia, etc., high values were found. In pernicious anemia lower and even normal values were found. Following splenectomy the urobilinogen in the feces may fall as low as 25-30 mg. daily, while in the urine the amt. may exceed 100 mg.

P. Y. JACKSON

The technic and theory of ultrafiltration. ALEX AUGSPERGER. *Physiol.-chem. Anstalt, Basel. Biochem. Z.* 196, 276-88(1928).—The effect of the membrane and of volatilization on the quant. results of ultrafiltration are discussed, and a special form of app. to avoid these errors is described. The requirement that an ultrafiltrate of const. compn. be furnished has been tested with gelatin + NaCl or serum + NaCl .

Colorimetric determination of lactic acid according to Mendel and Goldscheider. Physiological application. ANNELIESE HANSEN, OTTO RIESER AND IAKUJI NAGAYA. *Pharmakol. Inst., Univ. Greifswald. Biochem. Z.* 196, 301-8(1928).—A report of lactic acid detns. in muscles and brain.

S. MORGULIS

Methods for quantitative chemical analysis of skin. I. General principles. ERICH URBACH AND PAUL FANTL. *Universitätsklinik und Universitätsinstitut für med. Chemie, Wien. Biochem. Z.* 196, 471-3(1928).—A study of the dry residue, fat, protein and ash content of the skin leads to the conclusion that in a tissue lacking in homogeneity chemically and also so difficult to differentiate exactly anatomically, the results of analyses should be given in relation to its ash content (preferably on a fat-free basis) of the examd. skin fragment, this being the variable component. II. Sugar content of the normal skin. *Ibid* 474-7.—The skin fragment chosen for the study is clean shaven 24 hrs. before it is removed by the bloodless method of Kromayer using the elec. cautery. After sepg. the subcutaneous fat the skin tissue is at once placed in 2.5 cc. of 0.45% ZnSO_4 in a weighing bottle. After detg. its wt. the skin fragment (about 120 mg.) is comminuted by means of scissors which are also rinsed with 2.5 cc. 0.45% ZnSO_4 . To the 5 cc. ZnSO_4 is now added 1 cc. 0.1 N NaOH and heated 3 min. in the boiling water bath. The further technic is the usual Hagedorn-Jensen method for detg. sugar. In a no. of rabbits from which a no. of skin fragments were removed there has been found 89-144 mg. reducing substance per 100 mg. tissue (av. 112 mg. %), which corresponds closely to the similar values obtained for blood.

Double color colorimetry. E. KAUFMANN. *Biochem. Z.* 197, 141-2(1928).

S. MORGULIS

Lactic acid determination in uterus umbilical blood vessels. F. WIND AND K. V. OETTINGEN. *Kaiser Wilhelm-Inst. Biologie, Berlin-Dahlem. Biochem. Z.* 197, 170-4(1928).—No difference was found in the lactic acid content of the arterial and venous bloods.

S. MORGULIS

Preparation of ultrafilters with large pores. H. BECHHOLD AND K. SILBEREISEN. *Inst. Kolloidforschung, Frankfurt-a.M. Biochem. Z.* 199, 1-7(1928).—A method is described for the prepn. of permeable ultrafilters which depends upon the coagulation of the layer of acetic acid-collodion in acetic acid instead of water. The acetic acid must contain 18% water or more, the permeability diminishing with the increasing H_2O content. Ultrafilters of any desired porosity can be made by varying the concn. of the acetic acid-collodion and of the water in the coagulation mixt.

S. M.

Determination of small quantities of bismuth in urine and in organs. J. BODNAR AND ANTON KARELL. *Med.-Chem. Inst. Univ., Debreczen. Biochem. Z.* 199, 29-40(1928).—Method of ashing: *Urine*.—Urine is evapd. to dryness in a flat, porcelain dish. This is then supported about 10 cm. above an asbestos plate which is heated to such a degree that the contents of the dish smoke. When the smoking has ceased, the dish is gradually lowered and the contents are carbonized. The dish is heated for a few min. with the open flame which is constantly moved about. After cooling, the carbonized mass is finely powd. and completely moistened with 10% H_2O_2 . This is dried over the asbestos plate and heated with an open flame until most of the C is oxidized. If the ash is still grayish, the treatment with H_2O_2 is repeated. Finally the ash is moistened with concd. HNO_3 and heated once more when a snow-white residue remains. *Tissue*.—For the ashing of muscles and other organs a different procedure is advised. About 20-100 g. of the finely divided tissue is evapd. to dryness in a flat, porcelain or quartz dish. Enough $\text{Ca}(\text{NO}_3)_2$ soln. is added to give 1 cc. for each 10 g. tissue (the soln. is prepd. by dissolving 30 g. CaCO_3 in HNO_3 and dilg. with 20% HNO_3 to 100 cc.), then 1-2 cc. concd. HNO_3 . The dish is placed on the water bath and HNO_3 is added with const. stirring until a yellow pasty mass is produced, which is then evapd.

to dryness. The ignition is now carried out as before omitting, however, the H_2O_2 . The reaction of Bi with KI producing a yellow color is utilized for the colorimetric detn., the reaction being still pos. with 0.0016% Bi. The ash is boiled with 5 cc. 10% HNO_3 and the hot soln. is filtered through a small paper into a test tube marked at 20 cc. The dish and the filtrate are rinsed twice with 5 cc. 10% HNO_3 . The filtrate should be crystal clear and colorless; otherwise it is decolorized with a little Merck animal charcoal. Add to the soln. 6 drops of 1% $NaHSO_3$, 3 drops 1% starch soln., 2 cc. 20% KI and dil. to 20 cc. with water. For comparison a standard soln. contg. 0.1 mg. Bi per cc. is prepd. in HNO_3 . The comparison in the colorimeter should be made at once.

S. MORGULIS

Behavior of different sugars in the Bang microdetermination. BÉLA RÓHNYI. *Physiol.-chem. Inst. Königl. ungar. Univ. Budapest. Biochem. Z.* 199, 48-52(1928).—With the reduction of glucose as a basis of comparison, the reduction by xylose, fructose, galactose, lactose and maltose diminishes gradually to only 50%. In this respect the Bang procedure gives much lower results than the method of Bertrand. By the latter the reduction of glucose, xylose and fructose is the same. The paper contains a table of the factors for calcg. from the cc. 0.01 $N Na_2S_2O_3$ the mg. of resp. sugar.

S. MORGULIS

A microchemical demonstration of some barbituric acid derivatives in the urine. O. EHRLSMANN AND G. JOACHIMOGLU. *Pharmacol. Inst. Univ. Berlin. Biochem. Z.* 199, 272-5(1928).—The method depends upon the sublimation of veronal and other barbituric acid derivs. upon microscope slides. The sublimation is carried out by means of a specially constructed heater described and pictured in the text. This is provided with a thermoregulator. A quantity of urine suspected to contain veronal in amts. of 1-5 mg. per 100 cc. is evapd. to small vol., treated with tartaric acid and extd. with 30 cc. ether. The ether is carefully driven off at 30°, the residue taken up in 1-2 cc. $CHCl_3$ and transferred drop by drop to the sublimation app. For veronal the sublimation is continued for 12 hrs. at 70-80°, and even 0.5 mg. can still be detected by an examn. of the sublimated crystals.

S. MORGULIS

The applicability of the Schiff fuchsin-sulfurous acid reaction to the determination of thymonucleic acid. GASTA WIDSTRÖM. *Karolinisches Inst., Stockholm. Biochem. Z.* 199, 298-306(1928).—The reagent is prepd. by passing SO_2 through a 0.35% aq. fuchsin soln. until a permanent straw yellow color is obtained. The excess of SO_2 must be removed *in vacuo*. The test is carried out by one of the following procedures: (1) The sample is hydrolyzed in a boiling water bath with 6-8 cc. 0.05 $N HCl$ and cooled. It is then neutralized with 0.1 $N NaOH$, 2 drops of dinitrophenol being used until the first yellow color appears. An equal vol. of buffer is added. 1-3 cc. of this hydrolyzate are mixed with 10 cc. buffer soln. and 0.5-1.0 cc. of the fuchsin reagent. (2) The alternative method is to add about 8 cc. buffer to the sample previously acidified to Congo red with HCl ; the total vol. should not exceed 10 cc. The hydrolysis is performed as before. To the hydrolyzate are added 3 cc. of a mixt. of 1 part fuchsin reagent and 2 vols. buffer. The buffer was prepd. from 30.5 citrate soln. and 69.5 cc. 0.1 $N HCl$ to have a $p_H = 2$. (Michaelis.) The thymonucleic acid prepn. was made from a biuret-free Na salt contg. the correct N:P ratio. The thymonucleic acid content was detd. from the N. By this colorimetric procedure it is possible to measure the thymonucleic acid in a protein-free mixt. or in the presence of very little protein with an accuracy of about 2%, provided the hydrolysis of both the known and the unknown sample is carried out for the same length of time and at the same degree of acidity. The most suitable amts. of thymonucleic acid for analysis are 0.5 to 2 mg. S. M.

Determination of silver in biological fluids and tissues. EMMANUEL STERKIN. *Lab. pathol. Physiology, State Med. Inst., Charkow, U. S. S. R. Biochem. Z.* 199, 392-8(1928).—The detn. of Ag in biological materials depends on the ashing with concd. H_2SO_4 . The following reactions take place: $2 Ag + H_2SO_4 = Ag_2SO_4 + H_2$; $Ag_2SO_4 + 2 NaCl = 2 AgCl + Na_2SO_4$; $2 AgCl + H_2SO_4 = Ag_2SO_4 + 2 HCl$. In this way all Cl ions are converted to HCl which is boiled off. However, the complete freeing of the soln. from chlorides is not attained even after 105 hrs. of heating. This has been attained by means of nascent H_2 . The mixt. is dild. with 3-4 vols. of distd. water and 0.5-1 g. metallic Zn is added. The H_2 reacts with the $2 AgCl + H_2 = 2 Ag + 2 HCl$, and the chlorides are completely removed in 15-16 hrs., and Ag_2SO_4 is once more formed. When a solargentum soln. is injected intravenously the Ag disappears at once from the dog's blood and cannot be found by analysis. If enough Ag was administered to produce symptoms of poisoning or even death, the Ag can be always demonstrated in the blood. The time when Ag can be shown to be present in the blood corresponds exactly to the appearance of poisoning effects in the animals. If death,

regardless of the symptoms of poisoning, does not occur the Ag disappears from the blood.

S. MORGULIS

Studies on metal salt albumin solutions by means of the washing out method. HELMUT SCHORN. Inst. für Kolloidforschung, Frankfurt-a.M. *Biochem. Z.* 199, 459-67(1928).—A method is detailed for the prepn. of absolutely electrolyte-free egg albumin by a process of electroultrafiltration. The lowest pptn. zone of albumin by heavy metal salts is due to the presence of Ca, albumin free from Ca not showing this behavior. Water-sol. combinations were prepd. of albumin with Ag, Zn, Cr, Al, 1 g. equiv. of the metal combining with 5100-5200 g. of the albumin. Only combinations with FeCl₃ deviate from this behavior, probably because of the hydrolysis which takes place.

S. MORGULIS

Determination of chlorides in blood and urine by means of the conductivity titration. L. BUDAY. Pathol. Inst. Univ. Berlin. *Biochem. Z.* 200, 166-75(1928).—The cond. titration is carried out with the aid of a Kohlrausch wire bridge and telephone arrangement. One cc. of either urine or blood dild. to a vol. of 45 cc. is titrated with 0.1 N AgNO₃, a 2.0 cc. microburet being used. The material must first be acidified with dil. HNO₃. The curve is constructed by plotting the cc. 0.1 N AgNO₃ as abscissae and the readings on the bridge as ordinates, and presents a very characteristic course (different, however, for whole blood than for either urine or plasma). The results obtained by this method for plasma are identical with the Cl detn. by the Korányi method so that all the plasma Cl must be ionized or at any rate easily dissociable.

S. MORGULIS

A micromethod for the determination of phosphorus in tissue. YASUSHI NAITO. Biochem. Lab. Tokyo Imperial Univ. *J. Biochem. (Japan)* 9, 45-69(1928).—The method depends upon Neumann's reaction in which a ppt. of NH₄ phosphomolybdate of definite compn. is formed at 80° when a phosphate soln. contg. a certain amt. of NH₄NO₃ is treated with NH₄ molybdate at a definite acidity. The resulting ppt. is decompd. by NaOH: $2(\text{NH}_4)_3\text{PO}_4 \cdot 24\text{MoO}_3 \cdot 4\text{HMO}_3 + 56\text{NaOH} = 24\text{Na}_2\text{MoO}_4 + 4\text{NaNO}_3 + 2\text{Na}_2\text{HPO}_4 + 32\text{H}_2\text{O} + 6\text{NH}_3$, from which it is obvious that a minute quantity of P can be detd. by titration since 1 mol. P corresponds to 28 mol. NaOH. This method is suitable for the detn. of 0.1-0.005 mg. P in tissues, and for this amt. 3 cc. 20% H₂SO₄ gives the opt. acidity. The tissue and the acid are digested in a hard glass tube until the contents become black, the digestion being completed either with HNO₃ or H₂O₂. The H₂O₂ must be redistd. The heating must be carried out very carefully. To the digest (for instance, of muscle tissue) 3 cc. NH₄NO₃ soln. (30 g. in 100 cc.) are added and enough water to bring the vol. up to 9 cc. The mixt. is warmed to 80° and 1 cc. 10% NH₄ molybdate reagent is added. It is best to have the ppt. settle overnight. The ppt. is washed with 20% alc. An excess of 0.04 N NaOH is added and the NH₃ is removed by boiling. The excess alkali is titrated back with 0.04 N H₂SO₄ in CO₂-free air. Accurate results can still be obtained with 0.03 mg. P.

Certified biological stains. W. C. HOLMES. Color Lab. Bureau of Chemistry. *Am. Dyestuff Rept.* 17, 626-8(1928).—The progress in the manuf. and standardization of biological stains in America since 1920 is reviewed.

L. W. RIGGS

A rapid quantitative method for the determination of acetone and diacetic acid in urine. JEANETTE ALLEN BEHRE. *J. Lab. Clin. Med.* 13, 1155-9(1928).—A method is described for the detn. of urinary acetone and AcCH₃CO₂H, suitable for use in clinical labs. where a rapid and standardized procedure is necessary. The method is based upon the color reaction between salicylaldehyde and acetone in an alk. soln. Permanent standard solns. are described.

R. W. WICKWIRE

Improvements in Czapek's apparatus for determining surface tension (KAMINSKII)

C—BACTERIOLOGY

CHARLES B. MORREY

The bactericidal activity of hexylresorcinol (Solution S. T. 37) on wound surfaces. W. A. FEIRER AND V. LEONARD. *Surgery, Gynecol. and Obstet.* 47, 488-92(1928).—A simplified technic for the detn. of bactericidal activity is described. Solution S. T. 37 killed several types of bacteria, which usually infect wounds, in one minute in the presence of 3% peptone-gelatin, horse serum and rabbit blood and, disinfected wound surfaces freshly inoculated with these organisms. J. B. BROWN

The metabolism of amino acids by *Paramecium caudatum*. FREDERICK E. EMERY. Univ. Wis. *J. Morph. Physiol.* 43, 555-77(1928).—Expts. are made with *Paramecium caudatum* in 0.1% amino acids solns. and in aminoids. The decrease in the formol titration after 12 hrs. was taken as an index of activity. Bacterial action under these conditions was slight. In the aminoid soln. 8% was utilized at 5°, 21% at 17°, 40% at 22° and 46% at 32°. The *Paramecium caudatum* was not killed at the temp. of 5° since 31% of the aminoid was utilized when it was exposed to a temp. of 22° for 12 to 24 hrs. subsequently. The rate of utilization of the aminoid was reduced by anesthetics as follows: normal (6 hrs.), 25%, ethylene 19%, CHCl_3 17%, Et_2O 8% and nitroglycerin (1:50,000 soln.) 1.5%. The rate of metabolism of the amino acids was as follows: phenylalanine 7.7, tryptophan 9.6, glycine 9.6, leucine 12.0, glutamic acid 13.2, alanine 15.5, arginine 15.9, tyrosine 17.7, aspartic acid 25.1, cysteine-HCl 26.3, glutamic acid-HCl 45.6 and a mixt. of all except arginine 48.3%. The greater the rate of utilization the greater the rate of NH_3 production. *Paramecium* could not use cystine nor change it to cysteine but apparently uses the others as a source of energy. The results with histidine and lysine were inaccurate but probably amount to between 10 and 15% for the former and 5% for the latter. H. J. DEUEL, JR.

The poisonous action of some metals and metallic alloys on bacteria. G. TAMMANN AND W. RIENÄCKER. Univ. Göttingen. *Z. anorg. allgem. Chem.* 170, 288-300 (1928); *Nach. ges. Wiss. Göttingen math.-physik. Klasse* 1927, 158-71.—The growth of *B. brassicae* and *B. aceti* was not prevented at a definite concn. of Ag but a retardation occurred over a broad range from 1.10^{-5} to 1.10^{-3} g. Ag per l. In this range complete cessation of growth and no effect were both noted. The $[\text{Ag}^+]$ in the nutrient broth was about 1.10^{-5} . The Ag was in an org. complex but is toxic. A toxic action was exerted also by pieces of purified metal 6 to 8 mm. long and wide when these were introduced into the Petri dishes contg. bacterial cultures in nutrient media (*B. coli communis* in gelatin at 20° and *B. brassicae*, *Sarcina agilis*, *B. gossypii* or *Penicillium glaucum* in agar-agar medium at 35°). The strongest toxicity was caused by Hg, Cu (except on *B. coli communis*), Ni, Co and Sb. A medium effect was noted from Zn (slight effect on *B. gossypii*), Cd and Ag. The following metals exerted only a very weak toxic action: Al, Cr, Mn, Fe, Bi, Au and Pt. The toxic action of Al, Cr and Mn could be traced to impurities in the metals. With Hg and Ag, there were sharply differentiated zones around the metal, first one 3-5 mm. broad in which there is no growth detectable with the naked eye; a second zone 10-12 mm. wide in which there is retarded growth; then a small zone in which the growth is greater than normal while the area further distant from the metal shows normal growth. The lack of growth in the inner area is caused by the immediate soln. in the medium of the layer of oxidized metal on the surface of the piece of metal introduced. This results in the death of the bacteria in this area. After the soln. of this layer the dissolved O_2 in the medium slowly dissolves the metal and this diffuses out, causing a decreased growth of the bacteria in the second zone. The geometrical site of the zone limit depends on the concn. at the metal surface, the diffusion rate and the rapidity of bacterial growth. Cu is toxic in greater concn. than 5.10^{-3} g. Cu per l. but with smaller quantity growth is not prevented with *B. gossypii*. *B. coli* is insensitive to the Cu plates. The Ag-Au alloy was found less toxic than the Cu-Au alloy. H. J. DEUEL, JR.

Studies in the metabolism of *Aspergillus oryzae*. II. HIROSHI TAMURA. Imperial Univ. of Tokyo. *Acta Phytochim. (Japan)* 4, No. 1, 77-213(1928); cf. C. A. 22, 1990.—The effect of metals on the growth and metabolism of *A. oryzae* was investigated with different acidities of the nutrient media. Large addns. of the alkali metals did not modify the p_H growth curves. Alk. earth metals in high acidity aided growth; in low acidity they produced inhibition. Similar, although varying, results were obtained with Al, Fe, Co, Ni and Mn. With a p_H of 4 or 5, even small addns. of Zn, Cu Hg and Ag accelerate growth but in a higher or lower p_H an inhibition was noted. The alc. fermentation during growth is greater in young mycelium and when the reaction is near p_H 5-6. At this acidity autolysis of the fungous body is insignificant and the

quant. relationship of the alc. formed to the CO_2 produced is approx. 1:1. At other acidities the quantity of CO_2 drops. Alc. is also formed in smaller quantity in aerobic conditions but is increased with the depth of the fungous film in the soln. Aerobic metabolism is more vigorous in the early stages of growth. Its optimum pH lies at 6 or 7. Eliminating any of the nutrient salt components from the media in aerobic cultures produces a slight drop in growth; the opposite holds for anaerobic cultures. Aerobic cultures are influenced in various ways upon the addn. of ZnSO_4 , FeCl_3 , CaCO_3 , lactic acid and oxalic acid while no apparent change is noted in anaerobic cultures with the exception of CaCO_3 . A culture kept for a long time under anaerobic conditions will regain normal growth when placed under aerobic conditions. Thirty-six tables of data are appended.

RUSSELL C. ERB

The cytochrome in mold fungus cells. HIROSHI TAMIYA. Tokugawa Biol. Inst. *Acta Phytochim. (Japan)* 4, No. 1, 215-8(1928).—Expts. lead to the conclusion that the hemochromogen reaction that can be shown with a pyridine ext. of the fungus does not necessarily arise from the cytochrome found therein.

RUSSELL C. ERB

Oxidative changes produced in the iron-containing component of hemoglobin. Recognition of the oxidative faculty of living bacteria. K. BINGOLD. *Klin. Wochschr.* 7, 928-31(1928).—Oxyhemoglobin and methemoglobin are not decolorized by H_2O_2 . Hematin is decolorized. Dihn. of blood with H_2O leads to a loosening of the union between hematin and globin. Hematin does not actually sep.—the spectroscope shows nothing but oxyhemoglobin—but it is now held loosely enough so that H_2O_2 can produce oxidative changes. By varying the amt. of water it is possible to obtain all degrees of oxidation from none, through partial (green coloration) to complete (colorless). A limited no. of bacteria are able to produce similar changes in the blood pigments. The active agent is a peroxide which is produced by the bacteria.

MILTON HANKE

Differentiation of true paratyphoid B from the Breslau-enteritis bacteria on ammonium chloride-rhamnose agar. K. HOFMEIER. *Klin. Wochschr.* 7, 1692(1928).— NH_4Cl -rhamnose agar is not suitable for the certain differentiation of paratyphoid B from the Breslau-enteritis bacteria because certain strains of paratyphoid B and of Gärtner bacilli will grow readily on this medium.

MILTON HANKE

The binding of the bacteriophage. K. V. ANGERER AND H. RUPP. *Arch. Hyg.* 99, 118-29(1928).—A culture of Flexner bacteria grown upon agar or bouillon, and killed by exposure to a temp. of 60° for $\frac{1}{4}$ -1 hr., quickly binds a corresponding bacteriophage. The rates of the reaction at different concns. of bacteria and of bacteriophage did not fit exactly the equation for a mono-, di- or tri-mol. reaction; but the final equil. of bacteria and bacteriophage can be expressed by the adsorption isotherm in which the adsorption exponent = 0.8. The rate of binding was increased by temps. between 37° and 60° ; but was decreased by the addn. of gelatin.

P. Y. JACKSON

The minimal "chlorine death points" of bacteria. I. Vegetative forms. FRED O. TONNEY, FRANK E. GREER AND T. F. DANFORTH. *Am. J. Pub. Health* 18, 1259-63(1928).—The results of expts. appear to furnish a satisfactory theoretical basis for the current practice of relying on the destruction of *B. coli* in water as a criterion of effective chlorination and may also justify a more general application to other phases of Cl disinfection such as washing of milk bottles, eating utensils, etc. Among the various organisms studied (viz., *B. typhosus*, *B. paratyphosus* A and B, *B. dysenteriae*, *B. enteritidis*, *B. proteus*, *Cl. welchii*, *Bruc. melitensis*, *Staph. albus*, *Pneumococcus*, *C. diphtheriae*, *Strep. scarlatinae*, *Strep. fecalis*, *Staph. aureus*, *Strep. hemolyticus*, *B. pyocyaneus*, *Achromobacterium viscosum*, *B. suispestifer*, *B. prodigiosus*, *Bruc. abortus*, *Strep. morbilli* and *B. coli*) *B. coli* proved on the whole to be more resistant to free Cl than any of the others. Being readily available, having a rapid growth and readily detectable is therefore most suitable for use as an index of effectiveness of Cl sterilization. The amt. of Cl required to kill most of the intestinal pathogens was 0.1 p.p.m. with the greatest destruction of organisms occurring during the first 15 seconds exposure. A table giving the dosage of Cl required to kill the vegetative cells of the bacteria mentioned above is given.

N. A. LANGRISH

The enzyme metabolism of bacteria. V. Experiments on *Staphylococcus*. H. W. NICOLAI AND N. KAGEURA. *Pathol. Inst. Charité, Univ. Berlin. Biochem. Z.* 196, 246-56(1928).—*Staphylococcus* splits anaerobically glucose and levulose into 2 mols., and maltose and sucrose into 4 mols. of fixed acid. The rate of hydrolysis like the respiration is proportional to the cell concn. The staphylococci are very sensitive to changes in pH . The pH of the blood offers an opt. The temp. coeff. for the respiration and glucolysis is 2.27-2.60. Glucolysis and respiration are easily affected by changes in osmotic pressure. In isotonic solns. the earthy alkalies, especially Mg-

Cl_2 have an inhibitory action; the enzyme activity in KCl is better than in NaCl.

S. MORGULIS

Quantitative enzyme determinations on microorganisms. II. The effect of certain factors on the catalase content of bacteria. ARTURRI I. VIRTANEN AND A. O. WINNIE. *Biochem. Z.* 107, 210-21 (1938).—The production of catalase by *B. coli* is independent of the H-ion contn. of the nutritive medium. In bacteria grown at pH 4.8 to 8.5 the coeff. of catalytic activity was practically the same. The very low catalase content observed in media contg. glucose is attributed to the strong acid production which caused the death of many organisms. The catalase production is independent of the nature of the N or C source, and the same catalase coeff. was found either in a peptone soln. or in a sugar $(\text{NH}_4)_2\text{SO}_4$ soln. Milk and pyruvic acid had no effect on the catalase content. *B. coli* grown in strongly oxygenated media contain perhaps somewhat more catalase than those grown in O_2 -free media, but at any rate the difference is not large. S. M.

S. M.

Alcoholic sugar hydrolysis through acetic acid bacteria. CARL NEUBERG AND ERNST SIMON. Kaiser Wilhelm-Inst. Biochemie, Berlin-Dahlem. *Biochem. Z.* 197, 250-60(1928).—Acetic acid bacteria (*B. ascensens* and *pasteurianum*) under anaerobic conditions produce typical alc. fermentation in a 1.2% glucose soln. S. M.

S. M.

Characterization of *Aspergillus niger* strains on the basis of their biochemical behavior. I. Comparative studies on the acid formation of different strains of molds. K. BERNHAUER. Chem. Lab., deut. Univ. Prag. *Biochem. Z.* 197, 278-86 (1928).—Strains I and V are gluconic acid producers and do not form under any circumstances appreciable amts. of citric acid. Strain II is a good citric acid producer, while III and IV are intermediate types producing equal amts. of gluconic and citric acids under proper conditions. Much gluconic acid is produced by all molds in the absence of N salts and in the presence of CaCO_3 or CaO in the culture fluid; on the contrary, the max. citric acid production occurs only in the presence of N salts, and even molds which do not form citric acid show a tendency to produce some citric acid while the gluconic acid production is inhibited. S. MORGULIS

S. MORGULIS

Acid formation by *Aspergillus niger*. IV. Significance of the mycelium development on the acid production. K. BERNHAUER. Chem. Lab., deut. Univ., Prag. *Biochem. Z.* 197, 287-308(1928); cf. *C. A.* 22, 3187.—The quantity and quality of the N are essential in detg. the acid formation by mold developing in a N-poor medium produce gluconic acid almost entirely in the CaCO_3 when transferred to another culture medium. The acid is completely independent of the N source, and the opt. is at a concn. of 0.01-0.1%. Citric acid formation was found only in molds which had been grown on a N-rich medium. For development of these strains of molds $\text{NH}_4\text{H}_2\text{PO}_4$ and NH_4NO_3 are the best N sources, next KNO_3 and $(\text{NH}_4)_2\text{SO}_4$ while peptone is not suitable. S. MORGULIS

S. MORGULI

* Chemistry of citric acid production by molds. I. Acid formation from various carbon compounds. K. BERNHAUER. Chem. Lab., deut. Univ., Prag. *Biochem. Z.* 197, 309-28(1928).—The citric acid production from a variety of org. compds. is given. II. Citric acid production from gluconic acid. *Ibid* 327-42.—During the sojourn of mold in a soln. contg. 10% glucose and CaCO_3 there seem to be formed enzymes which facilitate the conversion of Ca gluconate into Ca citrate. This is obvious from the fact that such molds can produce more citrate from Ca gluconate than those taken directly from the culture medium. Another point of favorable evidence for the assumption of an enzyme formation is the greater production of citrate in the fluid which has not been heated as compared to the fluid which was heated for an hr. at 100° , indicating the presence of a thermolabile agent.

Loss of capacity to form acid and change in the acid in the case of Gluconic acid in place of fumaric acid fermentation.) C. WEHMER. *Microbiol.-chem. Lab. Technische Hochschule, Hanover. Biochem. Z.* 197, 418-32(1928). S. M.

The biochemistry of paratyphoid B. Schottmüller and Bac. enterit. Breislau as well as a new differential medium for these. M. N. FISCHER AND A. J. BUNTE. Botkin-Barackenkrankenhaus, Leningrad. *Biochem. Z.* 198, 428-41 (1928).—In autoclaved milk there is a condensation of amide N with sugar, a humin-like substance resulting where N is not easily assimilated by microorganisms. Paratyphoid B. Schottmüller can be differentiated from Bac. Breislau because the former does not, whereas the latter does, assimilate the N of this condensation product. The same condensation product can also be formed from aldehydes and amide N under ordinary temps. and pressure. In practice the bacteriological differentiation is carried out with an autoclaved mixt. made up as follows: lactose 2, $(\text{NH}_4)_2\text{SO}_4$ 0.02, Na citrate 0.2, NaH_2PO_4 0.05 and H_2O 50, which is mixed with 50 cc. 4% agar contg. 0.5% NaCl. This is autoclaved at 125-

127° for 40-60 min. The other mixt., not to be autoclaved, is made up as follows: AcH 0.1, urea 0.02, Na citrate 0.2, NaHPO₄ 0.05, water 50, and mixed with 50 cc. agar soln. contg. 0.5% NaCl.

Effect of temperature on the growth process of molds. RUDOLF MEYER. Inst. landwirtschaftliche Bakteriologie, Univ. Göttingen. *Biochem. Z.* 198, 463-77(1928).—M. concludes from his exptl. studies that it is not permissible to speak of an "opt. temp." except in this sense that it is the temp. which permits the greatest rate of growth under strictly specified other conditions.

The relation between the tangent of the nitrogen production curve and the supply of phosphoric acid in *Aspergillus niger*. An objection to Mitscherlich's law of action of growth factors. RUDOLF MEYER. Inst. landwirtschaftliche Bakteriologie, Göttingen. *Biochem. Z.* 199, 171-4(1928).—A criticism.

The different processes involved in alcoholic sugar hydrolysis and the acetaldehyde-dismutation. CARL NEUBERG AND ERNST SIMON. Kaiser Wilhelm-Institut für Biochemie, Berlin-Dahlem. *Biochem. Z.* 199, 232-47(1928).—The 2 acetic acid bacteria, *B. ascendens* and *B. pasteurianum*, which produce with utmost ease the quant. dismutation of simple aldehydes and keto-aldehydes give no evidence of the presence of apozymase or cozymase.

The role of oxygen in the oligodynamic action of metals. G. M. VAINDRACH. Sanitary-Bacteriol. Inst., Vjatka. *Zhurnal exptl. Biol. Med.* 10, 206-11(1928).—The oligodynamic action of Ag powders on staphylococci has been studied in a H₂ atm. The oligodynamic effect could be completely suppressed by displacing the air with H₂. Oligodynamy is regarded as a catalytic oxidative action caused by the traces of metal adsorbed by the living organism.

A sporulated thermophil bacillus functioning as a lactic enzyme. G. GUITTONNEAU. *Compt. rend.* 187, 69-72(1928).—The bacillus in question was isolated first from the sludge of Dax, previously maintained at 68° to 70° for several days. It multiplies readily in manure or fertile soil. The name *Thermobacillus tarbellicus* is proposed for this organism. It grows well in a medium consisting of K₂HPO₄ 1, MgSO₄ 0.2, FeSO₄ 0.01, ZnCl₂ 0.005, MnCl₂ 0.005, Defresne peptone 15, sucrose 40, tap water 1000 g. This soln. is neutralized by NaOH to phenolphthalein and there was added a large excess of CaCO₃. Growth in this medium was completely prevented by a temp. of 40° or 75°. A max. growth occurred at about 68°. The organism is not killed at 100° for 1 hr. It appears indifferent to the presence or absence of O, and develops within a pH range of 6.0 to 9.0. It causes the nutritive liquid to become acid with a pH of 5.5 by the production of lactic acid at the expense of the sucrose. It remains perfectly colored by the method of Claudius but not by the method of Gram.

Respiratory pigment, cytochrome, in bacteria. HIDEAKI YAOI AND HIROSHI TAMIYA. *Proc. Imp. Acad. Tokyo* 4, 436-9(1928).—A close parallelism between the cytochrome content and the intensity of aerobic respiration holds in all of the bacteria examd. The general aspect of the spectrum, however, varies much with the strains examd. In most of the aerobic bacteria studied, cytochrome was always found with its 4 characteristic bands (a, b, c, and d). In all strains of *B. dysenteriae*, excluding Shiga bacilli, and of *B. coli* there was an extra band in the spectrum at 623-637μ besides the known bands of cytochrome.

Bacterial filters. S. P. KRAMER. *Science* 68, 88(1928); cf. C. A. 20, 3481.—A filter which could remove both pos. and neg. colloids was prepd. by adding to the siliceous material in the filter compd., a basic material carrying a pos. elec. charge. Such a basic material is MgO calcined at 1300°. Equal parts of this calcined MgO with Florida kaolin and fired at a temp. not above 900° give a filter which will remove both acid and basic colloid dyes. It will also remove bacteria. The bacteriophage and the virus of mosaic disease of tobacco do not pass through these filters.

Sterilizing flask for bacteria cultures. MARIAN W. HEILMAN. U. S. 1,688,144, Oct. 16.

D—BOTANY

THOMAS G. PHILLIPS

The conduction of tropic excitation. ADOLF BEYER. *Z. Botan.* 20, 321-417 (1928).—The question is investigated as to whether the process of the conduction of stimulation in phototropism and geotropism is dependent upon an unlike distribution of normally present growth-promoting materials (Cholodny-Went hypothesis) or whether one must assume the production of special "trophohormones" (Stark hypothesis), that is, — simply cause a redistribution of substances already present

or does it induce the formation of new specific materials. It is shown that phototropic stimulation is conducted equally well by either the posterior or anterior flank of the plant material and that therefore the idea on which the Cholony-Went hypothesis is based, namely that the conduction of stimulation is limited to particular localities, must be abandoned. In the second place it was detd. that from the quant. standpoint the parallel to be expected between regeneration of growth-promoting material in decapitated plants and their ability to respond to phototropic stimulation does not exist. Both observations are in favor of the Stark hypothesis. R. C. BURRELL

A study of the grand period of growth in bamboo. WM. M. PORTERFIELD, JR. Columbia Univ. *Bull. Torrey Bot. Club* 55, 327-405(1928).—*Phyllostachys quadrangularis*, an autumn-growing species, and *P. nigra*, a spring-growing form, were measured daily during the growing periods in 1924-1926 at Shanghai, 10 shoots of each species being used in each year. All individual shoots of the same species have a grand period of similar extent in time and a growth curve of similar form, always much steeper in *P. nigra*, which completes its growth in the warm, rainy spring in about half the time required by the other species in the dry, cooler autumn. Comparison of individual growth curves show synchronous oscillations without regard to species or stage of growth, obviously induced by external conditions, and agreeing exactly with concurrent depressions in mean daily temp. As the day length was practically equatorial throughout the working period, no attempt was made to det. the effect of light intensity or length of day on growth rate. There was no correlation between rainfall or humidity and growth rate, which appears to follow strictly the rise and fall of temp. The actual growth curves agree very closely with those calcd. from Robertson's formula and support the conception that growth is an autocatalyzed monomol. reaction. The bibliography contains 59 titles. JOSEPH S. CALDWELL

The effect of a manganese deficiency on the sugar cane plant and its relationship to Pahala blight of sugar cane. H. ATHERTON LEE AND J. S. MCHARGUE. *Phytopath.* 18, 775-86(1928).—The name Pahala blight is applied in Hawaii to a disease of cane characterized by partial chlorosis and stunted growth, heretofore regarded as resulting from attack by *Mycosphaerella striatiformans*. In field expts. in Hawaii affected plants dusted with $MnSO_4$ made partial to complete recovery and any soil treatment which tended to increase the Mn content of the soil or to increase its availability was also beneficial. Plants grown in a greenhouse at Lexington, Kentucky, in Mn-free sand cultures developed the typical chlorotic conditions; checks with Mn remained healthy. Chlorotic leaves showed much lower content of Mn than normal green leaves. The condition should be renamed Mn deficiency chlorosis. JOSEPH S. CALDWELL

Application of the Donnan equilibrium to the ionic relations of plant tissues. GEO. E. BRIGGS AND ARTHUR H. K. PETRIE. St. John's College, Cambridge. *Biochem. J.* 22, 1071-82(1928).—The conception of a simple Donnan membrane equil. operating between 2 homogeneous phases is inadequate to explain the phenomena of ionic intake by plants. BENJAMIN HARROW

Biological investigations on radiation. I. Action of Röntgen rays on the development of germs. EGON BERSA. *Anz. Akad. Wiss. Wien* 63, 200-1(1926).—All studies connected with Röntgen rays and a material as variable as germs should use a statistical method. In only a few cases did a weak Röntgen treatment favor the development of the germs of *Vicia faba* and *Sinapis alba*. Such treatment never was favorable to the root system. *Sinapis* showed a very apparent depression in the root development. The depression is temporary and, within certain limits, inversely proportional to the treatment intensity. With very resistant plants (*Zea mays*), the development of the roots could be totally stopped. The phenomenon was temporary. A. L. HENNE

Is the retarded growth of germinated seeds subjected to x-rays due to an influence exerted on reserve food materials? SUZANNE ANCEL. *Bul. soc. bot. (France)* 74, 12-17(1927).—Cotyledons, stem, and root of germinated seeds of *Lentilla lens* were subjected simultaneously and separately to x-rays to det. what part of the young seedling was actually injured by such treatment. When the roots alone were irradiated, approx. the same marked retardation of growth of the main root resulted as when the entire seedling was exposed to the x-rays. Under similar treatment the stem and secondary roots showed only a slightly retarded growth. Irradiation of the stem alone retarded stem and secondary root growth but failed to affect the development of the main root. When only the cotyledons were irradiated, stem and secondary root growth were usually retarded to a much greater degree than growth of the main root. Injury resulting from irradiation of the cotyledon alone was regarded as being due primarily to stem injury since part of the stem was enclosed by the cotyledon in the youngest seedlings. Variation in degree of injury was dependent to some extent upon the stem

length of the seedlings used, a stem length of 1 cm. being retarded in development more noticeably than a stem length of 2 cm. A stronger dose (80 H.) was more injurious than a weaker (10 H.) one. Conclusion: The reserve food materials are not specifically influenced by x-ray treatment, but the adverse effects are due to direct injury of stem and root cells. The seedlings, on moist cotton, were placed 28 cm. from the anticathode of a Coolidge tube. The spark equiv. was 23 cm. and the current 2.5 milliamp. Filters were not used. Intensity measurements were made with Solomon's ionometer.

A. E. HITCHCOCK

Cumulative effects determined by the successive action of two injurious factors on legume seedlings. SUZANNE ANCEL. *Bul. soc. bot. (France)* 74, 348-9(1927).—Young seedlings of *Lentilla lens* were exposed to x-rays (450 to 700 R.) and then mutilated by severing the stem from its root. The amt. of stem elongation after this treatment was compared with that of seedlings similarly mutilated but not irradiated. Mutilation of irradiated seedlings reduced stem growth by a value 25% greater than that for seedlings which were mutilated but not irradiated. These results do not substantiate the conclusions of Jungling (1924) and Nadson and Zolkevie (*C. A.* 20, 1649), namely, that 2 or more unfavorable growth factors (e. g., low temp. and desiccation) operate in a simple additive manner. The operation of growth-retarding factors is therefore not believed to be merely a simple addn. of each injurious effect as it is produced separately. There is, instead, an accumulative effect resulting from one adverse factor which causes a second adverse factor to operate in a more injurious manner than the latter would if acting alone.

A. E. HITCHCOCK

Photosynthesis. E. C. C. BALY. *Science* 68, 364-7(1928).—See *C. A.* 22, 3682.

E. H.

The latest development in the stock-poisoning plant situation in Indiana. ALBERT A. HANSEN. Purdue Univ. *J. Am. Vet. Med. Assoc.* 73, 471-4(1928).—The tremetol content varies in white snakeroot of different areas. To test for this constituent the suspicious material is extd. with petr. ether, ether or pure gasoline by agitating gently. The mixt. is allowed to stand $\frac{1}{2}$ hr. and then a few cc. of the supernatant ext. are layered over 2 cc. of concd. H_2SO_4 . The appearance of a red color at the junction of the 2 fluids indicates tremetol.

FRANCES KRASNOW

The composition of the cell wall in the leaves of the white cabbage. HANS PRINGSHEIM, KLARA WEINREB and ERICH KASTEN. *Ber.* 61B, 2025-8(1928).—To remove substances other than the cell walls, the leaves of the white cabbage were treated with 6-8% alkali for 14 days and then washed with water followed by 2% AcOH. Incrustations were still present so the material was treated with 0.2 N ClO_2 soln., then with 6% alkali and washed. The residue gave a pentose reaction and extg. with 18% alkali did not remove it. The product was remarkably resistant to acids, being insol. in 41% HCl or 80% H_2SO_4 . It was only slightly sol. in Schweitzer's reagent. It was converted

into a triacetyl hexosan (44.8% acetyl) which gave $\alpha \left[\begin{array}{c} 2 \\ 1 \end{array} \right] + 1^\circ$ in $CHCl_3$. On sapon. a polysaccharide was obtained which was not hydrolyzed by 2% HCl and had a pentosan content of only 4%. A 4% $CHCl_3$ soln. of the acetate was refluxed for 3 days with 0.1% anhyd. $PhSO_3H$ when a swollen mass having 25.5% acetyl content pptd. This substance was water sol. and was hydrolyzed by boiling with 2% HCl for 7 days. The hydrolyzed soln. was optically inactive and an osazone prepd. agreed in m. p. with galactosazone. Other membrane walls in the cabbage plant are composed of cellulose so it appears that a plant may build cell walls of different polysaccharides for different organs.

J. G. McNALLY

The formation of enzymes in ripening seeds. A. OPARIN and N. DYACHKOV. Karpow Inst. Chemie, Moscow. *Biochem. Z.* 196, 289-93(1928).—From the time the seed leaves the mother-plant there is no more amylase formed. Apparently, during ripening, amylase passes into the seeds from the vegetative portions of the plant. The peroxidase and catalase content increases in the early stages of ripening even when the seeds are detached from the mother plant, so that these enzymes must be produced in the metabolic process.

S. MORGULIS

Orthophosphoric acid as a stimulator of germinating energy and activator of germinating capacity of seeds. MIHOVIL GRAČANIN. Inst. Pflanzenbau, Kgl. Universität Zagreb. *Biochem. Z.* 195, 457-68(1928).—Treatment of seeds of *Beta vulgaris*, *Secale cereale*, *Vicia sativa*, *Helianthus annuus*, *Lulium perenne*, *Festuca arundinacea*, etc. with P_2O_5 resulted in a definite stimulation of the germination rate. For different seeds the opt. stimulating concn. of orthophosphoric acid varies from 0.05 to 1.0% P_2O_5 for a period of 15 hrs. But this is not the opt. concn. for the development of young

plants. Seeds of *Hordeum vulgare* which after 10 days' treatment in water showed only 2% germinating ability had 61% ability after 72 hrs. treatment with 1% P_2O_5 . On the other hand, in seeds of *Polygonum fagopyrum* with high germinating power no stimulating effect could be observed under treatment with P_2O_5 . The stimulating effect is ascribed to the H_2PO_4 ions. These expts. further demonstrate that, since the germinating power can be reawakened in otherwise non-germinating seeds, inability to germinate should not be confused with the dead condition. S. MORGULIS

The nourishment of plants with aldehydes. VIII. TH. SABALITSCHKA. Pharm. Inst. Univ. Berlin. *Biochem. Z.* 197, 193-6(1928).—Discussion. S. MORGULIS

Continued studies on the chemistry of angiosperm seeds and the natural and artificial external germination factors. I. Effect of frost on germinating capacity. ANNELESE NIETHAMMER. Inst. Botanik und Warenkunde, deut. techn. Hochschule Prag I. *Biochem. Z.* 197, 241-4(1928).—The effect of frost is in some respects similar to that of light, but neither is able to wake the resting seeds from their state of rest. II. Acetaldehyde. *Ibid* 245-56.—AcH can be found in variable quantities in many air-dried seeds. Following swelling the AcH content of germinating seeds is increased, but resting seeds (i.e., not germinating) contain no AcH. Seeds incapable of germinating show in some cases the presence of AcH but this is no longer increased as a result of swelling. Frost may cause an increase in the AcH content and at the same time there is an improvement in germination. Keeping in a warm bath causes a large increase in the AcH content and the germinating power is improved. III. Surface tension active substances. *Ibid* 199, 175-85.—A variety of seeds contain saponin. The effect of saponin substances has been studied on seeds contg. and seeds lacking saponin in the germination bed, but no marked differences were noted between them. A no. of other alkaloids were tested with the general outcome that the stimulation of the seed germination is thought probably to be due to influences on their respiration. S. MORGULIS

The role of phosphate formation in the intermediate carbohydrate metabolism of plants. H. K. BARENSCHEEN AND WALTER ALBERS. Inst. med. Chemie, Univ. Wien. *Biochem. Z.* 197, 261-77(1928).—During the process of assimilation and dissimilation in plants there is an increase in the org.-acid-sol. fraction of P which is due to the formation of carbohydrate phosphoric acid esters. S. MORGULIS

Formation of methanol in the autolysis of fresh tobacco leaves. CARL NEUBERG AND BERTA OTTENSTEIN. Kaiser Wilhelm-Inst. Biochemie, Berlin-Dahlem. *Biochem. Z.* 197, 490-501(1928); cf. C. A. 22, 666.—In the leaf portion 0.816-0.986% MeOH was found; in the ribs the total MeOH content was considerably higher, 1.225 to 1.288%. S. MORGULIS

Paspalum conjugatum grass from British Honduras. ANON. *Bull. Imp. Inst.* 26, 206-7(1928).—The sample contained: H_2O 8.8, crude proteins 6.6, fat 1.5, N-free ext. 45.8, crude fiber 27.7, ash 9.6%, nutrient ratio 1:7.5, food units 66, alkaloids none, which is very similar to the compn. of *P. conjugatum* from Java. A. P.-C.

The poisonous properties of "kiligi" tuber from Tanganyika. ANON. *Bull. Imp. Inst.* 26, 322-3(1928).—The plant, which is considered to be a species of *Courbonia*, contained no alkaloids, but on autolysis yielded 0.04% HCN, equiv. to 0.22% on the dry basis (H_2O 82.1%). The skin of the tuber, examd. separately, yielded no HCN. A. PAPINEAU-COUTURE

Hypostase—its presence and function in the ovule of the Onagraceae. DONALD A. JOHANSEN. Stanford Univ. *Proc. Natl. Acad. Sci.* 14, 710-3(1928).—The hypostase consists of a well-defined but irregularly outlined group of thick-walled cells at the chalazal end of the anatropous ovule. It appears to be a flexible adaptation to the environment and makes its appearance only when nature requires it. The hypostase and epistase, when either or both are present, serve to stabilize the water balance of the resting seed over the long period of dormancy during the hot dry season. L. W. R.

Spike disease of sandal (*Santalum album*). II. Analysis of leaves from healthy and spiked trees. A. V. VARADARAJA IYENGAR. *J. Indian Inst. Sci.* 11A, Pt. 9, 97-102(1928).—Sandal leaves affected with spike contain more free reducing sugars, total carbohydrates, starch, total N and dry matter than the healthy leaves. Leaves from diseased samples were deficient in Ca, K, H_2O and ash. III. Physico-chemical study of the leaf sap. *Ibid* 102-9.—The pH of healthy sandal leaf sap was 5.15 to 5.71; that of spiked trees was 4.69 to 4.99. The titratable acidity and osmotic pressure were higher in diseased samples. The sp. cond. of sap was always lower in the spiked samples, as was also the ratio of sp. cond. to f.-p. depression. L. W. RIGGS

Cress grown on adrenaline. J. H. THOMPSON. Middlesex Hospital Med. School. *Nature* 122, 401(1928).—Cress seeds grown on cotton pads soaked in a 1 to 10,000 soln.

of adrenaline and afterwards kept moistened with distd. water showed the following marked differences from control crops grown on distd. water: (1) The seeds germinated about 24 hrs. later. (2) After the preliminary retardation, growth advanced rapidly and in 3 days the plants were taller than the controls. (3) When maturity was reached the plants were much taller and the leaves were larger than the controls. Also, the plants were a paler shade of green. (4) The most striking feature was the presence of adrenaline or adrenaline-like compds. which gave the positive oxidizing tests for adrenaline. The controls gave none of these reactions. The cross was extd. with normal saline and injected into decerebrate cats, whereupon the pharmacodynamical reactions for adrenaline were observed.

L. W. RIGGS

Anthocyanin pigments of morning glory. II. TAKEO KATAOKA. *Proc. Imp. Acad. Tokyo* 4, 389-92(1928); cf. *C. A.* 21, 1652.—Further study has proved the identity of the aglycon of the anthocyanin pigment of the red flowers of the morning glory (*Pharbitis Nil* Chois.) and pelargonidin.

L. W. RIGGS

A stable colorimetric standard for chlorophyll determinations. JOHN D. GUTHRIE. Ohio State Univ. *Am. J. Botany* 15, 86-7(1928).—The usual standard for the detn. of chlorophyll, a soln. resulting from the sapon. of the pigment itself, has several disadvantages. Because of the ease of exact duplication and its stability the standard described does not have these disadvantages. A soln. consisting of a mixt. of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$, $\text{K}_2\text{Cr}_2\text{O}_7$, and NH_4OH is used as the standard. A table is given showing the % of chlorophyll detd. with the usual chlorophyll standard and the new standard.

E. F. SNYDER

Nitrogen metabolism in the soy bean. J. E. WEBSTER. Oklahoma Agr. and Mech. College. *Plant Physiology* 3, 31-43(1928).—Five series of pot culture greenhouse expts. were carried out using soy beans (*Glycine max.* var. Peking). In the 1st series, high-N plants were obtained by growing the plants in a soil rich in humus that received a supplemental application of dil. KNO_3 . The high-N plants of the 2nd series and the low-N plants of the 3rd series were obtained by growing the plants in sand cultures. High-N plants were obtained by using a stock nutrient soln. of 2% $\text{MgSO}_4 \cdot 2\text{H}_2\text{O}$, 2% KNO_3 , 10% $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ and 2% K_2HPO_4 . Fe was added as the citrate. The nutrient soln. used to obtain low-N plants was similar to that for high-N plants, except that only $\frac{1}{4}$ of the amt. of $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ was used. In the 4th series, low-N plants were obtained by the use of a stock nutrient soln. consisting of 2% $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, 2% KCl , 4% $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ and 2% K_2HPO_4 and in the 5th series low-N plants were obtained by growing them in quartz sand without the addn. of any nutrient soln. In the 1st 3 series, moisture, total N, sol. N, insol. N, ammonia N, amide N, amino N, nitrate and nitrite N detns. were made weekly for 10 weeks, on the leaves, stems and roots. In the 4th and 5th series the above detns. were made at bi-weekly intervals. The analytical data given are calcd. in terms of percentage of fresh wt. of material. Conclusions: (1) In general, the variations of the various types of N compds. in the roots, leaves and stems of any particular series are quite similar. (2) There is little or no evidence to support the idea that the leaves, stems, or if present, the seeds, draw upon the N reserves of the roots. (3) Amino acids having amide groupings, on the basis of the amt. present, are of no more importance in protein metabolism in plants than other amino acids, although there is some evidence to show that amide N may be one of the most sol. storage forms. (4) Addnl. proof has been found for the idea that NH_3 is the first and last product of N metabolism in plants. (5) There is considerable daily fluctuation of the various forms of N in no uniform direction. (6) Within a wide range, when the external N supply is the only variable, only the general appearance and not the physiol. cycle of the soy bean is changed.

WALTER THOMAS

The development of chlorophyll in seedlings in different ranges of wave lengths of light. J. D. SAYRE. Ohio State Univ. *Plant Physiology* 3, 71-7(1928).—Seedlings of corn, wheat, oats, sunflower, radish, mustard and bean were grown in daylight and also in the artificial light from a Mazda C. 400-watt lamp under colored glass $6\frac{1}{2}$ in. square ray filters manufactured by the Corning Glass Works. The same series as used by Popp (*C. A.* 22, 3191) was employed with a few addns. The chlorophyll content of the tissues was not directly detd., instead the relative greenness of the plants as compared with the controls grown under all wave lengths of light was used as the measure of the amt. of chlorophyll present. All plants were grown under similar temp., humidity and soil conditions, the variable being the different wave lengths of light. The transmission data for the colored plates used were obtained according to the methods of the Bur. of Standards (*C. A.* 13, 1136; 15, 2908) and the limits of transmission of each plate checked by a wave-length spectrometer. The plants were grown under ventilated light-proof tin boxes which held 4 glass plates. The boxes were painted white (MgO

paint) on the inside and with Al paint on the outside. The seeds were planted directly in the soil when the expts. were conducted out of doors and the tin boxes were sunk several in. in the soil to make a light-tight seal. For expts. under artificial light in the greenhouse, flats of soil were used and the tin boxes were sunk for several in. into a large tray of soil. The plants were placed 1 m. from the light. Relative to chlorophyll formation under these conditions, the following conclusions are drawn: Wave lengths of radiant energy longer than 680m μ are not effective in the formation of chlorophyll in seedlings of corn, wheat, oats, barley, beans, sunflowers and radish. All other regions of the remaining visible and ultra-violet spectrum (to 300m μ) are effective provided the energy value is sufficient. For approx. equal energy values in these regions, the red rays are more effective than the green, and the green more than the blue. The effectiveness of radiant energy appears to increase with wave length to about 680m μ and then to end abruptly.

WALTER THOMAS

Photosynthesis in absence of oxygen. E. NEWTON HARVEY. Princeton Univ. *Plant Physiology* 3, 85-9(1928).—Fourteen species of marine algae, including members of the green, red and brown groups, are able to produce O from CO₂ when illuminated in complete absence of O. The O appears within a second after illumination, showing the ready permeability of the plasma and cellulose membranes to this gas. Luminous bacteria are recommended as a test for O under all conditions where they will survive.

WALTER THOMAS

A study of the effect of hydrogen-ion concentration on the growth of *Agaricus campestris*. DONALD FREAR, J. F. STYER AND D. E. HALEY. Penna. State Coll. *Plant Physiology* 3, 91-4(1928).—Sterilized culture media consisting of black filter paper (Whatman's No. 29) 10.0 g., casein 0.6 g. and 20 cc. of the following soln.: MgSO₄·7H₂O 0.02 M., KH₂PO₄ 0.04 M., K₂SO₄ 0.01 M., FeSO₄·7H₂O trace, CaCl₂ trace, at various H-ion concns. were inoculated with a small piece of mycelium of the common mushrooms, obtained from a pure culture growing in manure. The culture flasks were placed in pans contg. moist sphagnum moss and incubated in the dark at 27°. Growth records, as detd. by the diam. of the colony, were made each week. The best growth was obtained in the cultures at or near pH 6.0. A decrease of as much as pH 2.0 occurred in the media in which the best growth was made. WALTER THOMAS

Effects of light upon nitrate assimilation in wheat. W. E. TOTTINGHAM AND HENRY LOWSMA. Univ. of Wisconsin. *J. Am. Chem. Soc.* 50, 2436-45(1928).—Data are presented from the growth of maize in H₂O cultures during late summer which indicate that the absorption of nitrate and synthesis of protein are promoted by light rays which are absorbed by greenhouse glass under the conditions here effective. Data are also presented from the growth of wheat in sand and H₂O cultures which were irradiated by elec. lamps for periods of 10-21 days; with total intensities of 200-1200 foot candles and upwards, the long ultra-violet region was increased about 50-400% by use of C arcs. The concomitant increase in red-orange rays was about 0.5-4%, with unmeasured increases in the shorter wave lengths of the visible spectrum. In the early growth phases of wheat, relatively limited increases in the proportion of shorter visible light rays greatly enhance the absorption of nitrate and significantly increase the synthesis of protein. These effects are accompanied by small increments of the % of H₂O₂ in the tissue and declines in the yields of sugar and total dry matter. Long ultra-violet rays seem to be effective in the absorption of nitrate, but the present results do not establish any further role. The proportion of blue-violet rays in the artificial light used was considerably smaller than in sunlight. Further study is desirable with sunlight or a similarly balanced spectrum.

The specific dynamic action of foods. A. BORNSTEIN. Univ. Hamburg and Krankenhaus St. Georg. *Deut. med. Wochschr.* 54, 1535-6(1928).—A review and discussion of the modern views regarding the specific dynamic action of foods. A. G.

Can ultra-violet rays increase the growth-promoting effect of iron? P. M. SUSKI. Pathol. Inst. Univ. Berlin. *Biochem. Z.* 199, 69-71(1928).—Measured by its influence

on the growth of young rats, ultra-violet radiation of FeSO_4 has no significant effect upon its biological activity. S. MORGULIS

F—PHYSIOLOGY

E. K. MARSHALL, JR.

The mechanism of intestinal secretion. M. P. BRESTKIN AND V. V. SAVICH. State Inst. Exptl. Med., Leningrad. *Arkhh. Biol. Nauk* 27, 37-44(1927).—Observations were made on 3 dogs with Thiry-Vella loops of the duodenum and jejunum. Accidentally in the first dog the constrictions at the ends of the loop were incompletely closed, and consequently the uninterrupted secretion of the juice could be observed. Feeding diminished the quantity of and the concn. of erepsin and kinase in the secretion. Soaps, fats and bread had the most marked effect. Liebig's ext. and acids had a feeble inhibitory effect. The inhibition of intestinal secretion by food at a distance is believed to be regulated by a nervous mechanism. The role of local impulses, humoral stimuli, and of inhibitory nerve stimuli in the function of the intestinal glands are discussed at length. W. A. PERLZWEIG

The role of the nervous system and adrenaline in the spontaneous contraction of the blood vessels. F. N. SPERANSKA-STEPANOVA. State Inst. Exptl. Med., Leningrad. *Arkhh. Biol. Nauk* 27, 45-54(1927).—In normal frogs the spontaneous contraction of denervated blood vessels is conditioned by the adrenaline of the blood which is capable of replacing the tonic effect of the sympathetic system. W. A. PERLZWEIG

The connection between the liver and the parathyroid glands. M. M. GORBUNOVA. State Inst. Exptl. Med., Leningrad. *Arkhh. Biol. Nauk* 27, 55-60(1927).—From perfusion expts. on the isolated livers of parathyroidectomized cats it is deduced that the parathyroids regulate the Ca metabolism in general and the Ca level in the blood. The removal of these glands and the consequent diminution of the blood Ca lead to a disturbance in the function of the endocrine glands, particularly of the liver, in which the capacity to retain NH_3 is greatly reduced. This latter impairment is partially overcome by means of administering Ca salts. W. A. PERLZWEIG

The influence of relative parathyroid deficiency on gastric secretion. S. I. LEBE-DINSKA. State Inst. Exptl. Med., Leningrad. *Arkhh. Biol. Nauk* 27, 61-75(1927).—Observations were made on dogs with Pavlov stomachs in whom 2 of the external parathyroids were extirpated and 1 internal gland was crushed. The deficiency so produced led rapidly to disorders in gastric secretion, notably to a hypersecretion and diminished enzyme content in the reflex phase. Later alterations appear in the chem. phase during which secretion is prolonged, then pass to an inert type, and finally culminate in severe hypersecretion. The combined administration of NaHCO_3 by rectum and of CaCl_2 by mouth tends to reestablish the normal reflex phase, to reduce spontaneous secretion and hypersecretion, and to bring the secretion time curve closer to the normal type. W. A. PERLZWEIG

Gastric secretion in relative parathyroid deficiency. L. I. PRAVDINA. State Inst. Exptl. Med., Leningrad. *Arkhh. Biol. Nauk* 27, 77-87(1927).—The results in the preceding abstr. are confirmed and extended. The transplantation of parathyroid glands into parathyroidectomized dogs restores the reflex phase and diminishes hypersecretion. The Ca of the blood rises. The dependence of the mechanism of gastric secretion upon the blood Ca level is discussed. The injection of testicular exts. (prepd. by Kravkov's method) induced favorable results in respect to gastric secretion in parathyroidectomized dogs. W. A. PERLZWEIG

Phosphorus metabolism. A. V. KHARIT AND A. I. LIVSHITZ. State Inst. Exptl. Med., Leningrad. *Arkhh. Biol. Nauk* 27, 89-99(1927).—Inorg. and total P were detd. in the serum and whole blood taken from different blood vessels of dogs under various metabolic conditions. The highest inorg. and total P were found in the portal vein, the lowest in the renal vein. The liver retains part of the inorg. and total P of the serum as well as of the whole blood. There is likewise a similar loss in the passage of the blood through the kidneys. The following ranges of serum P in the various vessels are given:

	Inorg. P	mg. % Total as P_2O_5
Portal vein	3.8-7.2	29.0-35.0
Hepatic vein	3.4-6.9	31.1
Renal vein	4.6-6.5	28.0
Femoral artery	3.1-6.8	27.0-6.8

The range of the whole blood P is analogous but somewhat higher. Evidence is presented that the constancy of the blood P level is maintained not only by the food, but

also in the absence of food, by the digestive secretions and by the products of tissue catabolism. The ingestion of P-rich food raises the level of P metabolism. W. A. P.

The influence of testicular preparations on the regressive changes in the secondary sexual characters in castrated cocks. A. I. KUZNETZOV. *Arkhh. Biol. Nauk* 28, 33-6(1928).—A report of neg. results. W. A. PERLZWEIG

The influence of gastroenterotomy upon the function of the gastric glands. M. P. BRESTEIN. State Inst. Exptl. Med., Leningrad. *Arkhh. Biol. Nauk* 28, 211-7 (1928).—Gastroenterotomy in dogs produces an uninterrupted secretory activity of the gastric glands. In this secretion the reflex phase is almost completely lacking, and in many cases a lowering of secretion results from the act of eating. Chem. stimulants exert their action, raising the secretion materially. Eats do not inhibit secretion while soaps do, behaving in the usual manner. W. A. PERLZWEIG

The suprarenal fluid and its properties. A. I. KUZNETZOV. State Inst. Exptl. Med., Leningrad. *Arkhh. Biol. Nauk* 28, 265-8(1928).—The fluid was obtained by Kravkov's method from the isolated suprarenal glands. It contains 2 groups of substances: those of the one resemble adrenaline and those of the other resemble muscarine. The fluid is distinguished from adrenaline by its greater stability and the duration of its effects. It was utilized in the treatment of Addison's disease. W. A. PERLZWEIG

The testicular fluid and its properties. A. I. KUZNETZOV. *Arkhh. Biol. Nauk* 28, 269-73(1928).—The fluid was obtained from isolated beef testes by Kravkov's method. It is claimed to possess a tonic effect upon cardiac muscle, the blood vessels, blood pressure and upon metabolic processes. Favorable results are reported after its therapeutic use in various sexual disorders. W. A. PERLZWEIG

The change in the vascular reactivity of the kidney after adrenalectomy. A. I. KUZNETZOV AND S. I. LEBEDINSKA. State Inst. Exptl. Med., Leningrad. *Arkhh. Biol. Nauk* 28, 261-4(1928).—The renal vessels in the isolated dog kidney after adrenalectomy react much weaker to vasoconstrictor poisons (adrenaline and BaCl_2) as well as to vasodilator drugs (caffeine). This is explained by the lowering of the tonus of the vessels because of the loss of irritability in the endings of the vasomotor nerves. W. A. P.

H. GIDEON WELLS

Newer aspects of liver disease. E. ANDREWS, W. A. THOMAS AND K. SCHLEGEL. *Surgery, Gynecol. and Obstet.* 47, 178-82(1928).—In certain diseases of the liver it is shown by serological methods that liver protein is excreted in the urine, accompanied by a disturbance of the mineral salt balance, especially Ca and Na. J. B. BROWN

The insulin requirement on various diets. N. R. BLATHERWICK, W. D. SANSUM, MARION BELL AND ELSIE HILL. Potter Metabolic Clinic, Santa Barbara. *J. Metabolic Research* 7-8, 39-49(1925-6).—The insulin requirement is not entirely dependent on the potential glucose of the food but upon all the foodstuffs comprising the diet as detd. by a prolonged expt. on a diabetic patient. H. J. DEUEL, JR.

Anomalous fat metabolism in a case of diabetes mellitus. I. M. RABINOWITCH AND E. S. MILLS. Montreal Gen. Hosp. *J. Metabolic Research* 7-8, 87-90(1925-6).—A report of a case in which on admission to hospital the blood fat showed an abnormally high value of 18.6%. After the administration of 50 units and later 20 units of insulin, the blood fat fell to 9.4% which would indicate the disappearance of about 460 g. of fat from the blood by storage in the tissues. Four hrs. later the blood fat had fallen to the value of 2.1%. It is suggested that insulin may cause an increased permeability of the tissues for fat. The importance of insulin in fat metabolism is emphasized. H. J. DEUEL, JR.

The glucose tolerance in arthritis. E. F. TRAUT. *J. Metabolic Research* 7-8, 187-93(1925-6).—There is a lowered glucose tolerance in some cases of arthritis, and in such generalized infections as rheumatic fever, tuberculosis and bronchopneumonia. In patients with localized freely draining infections the carbohydrate metabolism was normal. The lowered glucose tolerance in rheumatic fever continues over into early convalescence. H. J. DEUEL, JR.

The examination of the gastric contents as an aid to the diagnosis of carcinoma of the stomach. DERRICK M. DUNLOP. Chalmers Hosp., Edinburgh. *Edinburgh Med. J.* 35, 497-532(1928).—The results of gastric analyses by the fractional method in 93 cases are given. The important factors in the diagnosis of carcinoma are (1) achlorhydria, (2) lactic acid, (3) blood and (4) evidences of stagnation. The absence of free acid and the presence of lactic acid occur in the great majority of patients suffering from gastric carcinoma, these dual findings not occurring in any other condition

except carcinoma of the esophagus. The absence of lactic acid in stomach contents which show no free acidity or the discovery of large amts. of free HCl makes a diagnosis of gastric carcinoma highly improbable. Lactic acid found in the stomach contents is not always an indication of the stagnation of the gastric juice since sarcocollactic acid may be produced by the tissues involved in growth. This constituent may be found in the gastric juice in the absence of pyloric stenosis. The Congo red and the dimethyl tests for free HCl in gastric juice were found untrustworthy since they were not sensitive for small quantities of the HCl and they react with large quantities of lactic acid in the same way as with free HCl. Gunzberg's test when freshly prepd. reagent was used was found entirely reliable for free HCl. Uffelmann's test for lactic acid was found to be non-specific while MacLean's test proved satisfactory. H. J. DEUEL, JR.

An abnormality in the composition of human fat. S. V. TELFER. Western Inf., Glasgow. *Glasgow Med. J.* 110, 137-41(1928).—The fat obtained on autopsy from a diabetic had an I no. of 59.4 for the whole fat (normal value = 71.0). The insol. fatty acids had a m. p. of 36-37° (normally 32-33°), a solidifying point of 35° instead of the normal value of 30°, an I no. of 62.8 compared with the usual one of 78.6 and the percentage of sated fatty acids of 38.6 instead of 25.8. H. J. DEUEL, JR.

The changes in the ash constituents of the blood during experimental nephritis with special reference to the potassium and calcium value of the serum. ADOLF BOLLIGER AND FRITZ BREH. Henry Ford Hosp., Detroit. *Zentr. inn. Med.* 49, 825-31(1928).—The administration of urea in 30 or 40 g. doses to normal dogs did not change the normal level of serum K or Ca. Similar results were obtained on an animal with a kidney insufficiency produced by removal of one kidney and partial ligation of the renal artery to the other. These results support the view that urea has a non-poisonous property and are in contradiction to the work of Mark and Kohl-Egger (cf. *C. A.* 22, 812). In dogs in which a chronic interstitial nephritis was induced by exposure of the kidneys to the x-ray, the serum K value was somewhat raised 1 month prior to death (25 to 30 mg.) while values above 40 mg. (42-117 mg.) were characteristic of the last days of life. The rise in phosphate somewhat precedes that of K although the late rise in the K is paralleled by that of the phosphate. Because of the greater simplicity in the detn. of phosphate and its somewhat earlier rise, it is suggested that this substance is more satisfactory for the prognosis of a nearing death. The serum Ca may be raised, lowered, or remain unchanged in the uremic dog. The detn. of the alkali reserve in uremia showed that the acidosis is one of the most important factors and may be responsible for the death. The acidosis appeared a considerable time before the uremic state is pronounced. It is probably not to be traced to phosphate retention as assumed by Howland, since there is no parallelism with phosphate retention. H. J. DEUEL, JR.

The Müller-Ballungs reaction with special reference to results obtained with spinal fluid. GOTTFRIED ENGERTH. Psychiatrisch Neurologischen Klinik, Wien. *Deut. med. Wochschr.* 54, 1374-5(1928).—The Müller-Ballungs reaction is more sensitive than the Wassermann or colloidal Au reactions. It is neg. in non-syphilitic tumors, meningitic disease and multiple sclerosis. ARTHUR GROLLMAN

Blood-sugar changes during cures for morphinism by removal of the drug. Contribution to the etiology of psychomotor abstention phenomena. ARNOLD HIRSCH. Kuranstalten Westend, Berlin. *Deut. med. Wochschr.* 54, 1462(1928).—During the cure of the morphine habit, the blood sugar was abnormally low. Injection of sugar ameliorated the psychopathic manifestations usually accompanying sudden removal of the drug from addicts. ARTHUR GROLLMAN

Blood regeneration in severe anemia. XII. Potent influence of inorganic ash of apricots, liver, kidney and pineapple. FRIEDA S. ROBSCHT ROBBINS, C. A. ELDER, WARREN M. SPERRY AND G. H. WHIPPLE. Univ. of Rochester. *J. Biol. Chem.* 70, 563-76(1928).—Apricot feeding was highly potent in producing blood regeneration in anemic dogs. The inorg. ash of dried apricots retains this potency. Inorg. ash of beef liver and pig kidney are only half as potent as whole cooked organs. The ash of pineapple was only slightly potent. Analysis of the ash samples showed the apricot ash to be the richest in Cu. XIII. Influence of certain copper salts upon hemoglobin output. C. A. ELDER, WARREN M. SPERRY, FRIEDA S. ROBSCHT-ROBBINS AND G. H. WHIPPLE. *Ibid* 577-86(1928).—The effect of Fe, Cu and Zn salts when added to the diet of anemic dogs was studied. Cu salts had a positive effect on blood regeneration but FeCl₃ had a more notable effect. The effect of combined Fe and Cu feeding was variable. ARTHUR GROLLMAN

The protein content of the cerebrospinal fluid in myxedema. WILLARD O. THOMPSON, PHEBE K. THOMPSON, ESTER SILVEUS AND MARY E. DAILEY. Mass. General

Hospital, Boston. *J. Clin. Investigation* 6, 251-5(1928).—The protein content of spinal fluid was high in cases of myxedema and dropped under thyroid ext. therapy. A. G.

Chemical changes occurring in the body as the result of certain diseases. III. The composition of the plasma in severe diabetic acidosis and the changes taking place during recovery. ALEXIS F. HARTMANN AND DAN C. DARROW. Washington Univ. and Childrens Hospital, St. Louis. *J. Clin. Investigation* 6, 257-76(1928).—In severe acidosis marked concn. of the plasma occurs with slight diminution of total base. $[HCO_3^-]$ and $[Cl^-]$ are diminished relatively more than ketone acid and protein. "When therapy consists only of administration of H_2O and insulin, with or without carbohydrate, $BHCO_3$ and p_H are at first restored relatively very slowly because, as the base is released by oxidation of the salts of the ketone acids, it is claimed in large part by acids other than H_2CO_3 . Later, secretion of chloride, bound to NH_3 into the urine adds in the restoration of plasma $[BHCO_3^-]$. Salt administration adds little if any towards the early recovery of plasma $[HCO_3^-]$. $NaHCO_3$ administration with H_2O , insulin, carbohydrate and salt may provide a very rapid, safe and complete relief from acidosis.

ARTHUR GROLLMAN

Experimental modification of callus formation in bone fractures. K. GLASSNER AND J. HASS. Univ. Wien. *Klin. Wochschr.* 7, 1633-5(1928).—Exptl. evidence is presented that indicates that callus formation is greatly hastened by administration of thymus ext.

MILTON HANKE

Role of the hypophysis and the hypothalamus in experimental diabetes insipidus. PAUL TRENDLENBURG. *Klin. Wochschr.* 7, 1679-80(1928).—Diabetes insipidus may be due to a deficiency in 2 hormones. Removal of the hypophysis leads to diuresis and to the increased appearance, in the tuber cinereum, of a substance that acts as an antidiuretic. The tuber cinereum will, in time, assume the responsibilities of the hypophysis as an antidiuretic. Removal of the tuber cinereum at this time leads to a reestablishment of profound diuresis which is permanent.

MILTON HANKE

Activation of pancreas lipase in serum with leucylglycylglycine. A modification of the Rona test. ALFRED ROSEN. *Klin. Wochschr.* 7, 1693-4(1928).—The Rona serological method for diagnosing disease of the pancreas has been improved by adding leucylglycylglycine to the atoxyl-treated serum. The tripeptide activates the lipase and leads to a rapid hydrolysis of tributyrin. The 2-hr. reaction period of the Rona procedure is reduced to 7 min.

MILTON HANKE

Lactic acid content of the blood in hepatopathics. HERTHA SCHUMACHER. Med. Univ. Clinic, Frankfurt. *Klin. Wochschr.* 7, 1733-7(1928).—The lactic acid content of the blood is increased in severe, but not in mild, cases of liver injury. The injection of 4 g. Na lactate into hepatopathics leads to a more protracted rise in the blood lactic acid than is the case in normal individuals.

MILTON HANKE

The coagulation time and sedimentation time of blood after the parenteral administration of irritants. J. KNOSP. *Klin. Wochschr.* 7, 1909-11(1928).—Administration of the irritant, Clauden, leads to a decrease in the coagulation time and a parallel decrease in the sedimentation time. Injection of defibrinated blood has a similar, though a much less intense, effect.

MILTON HANKE

Action of various forms of iron on hemoglobin regeneration. GEORG STIEGER. *Klin. Wochschr.* 7, 1914(1928).—Iron as ferrum reductum, ferri chlorati, ferrum oxydatum saccharatum, dried blood or hematophan is equally valuable for blood regeneration in dogs after severe hemorrhage.

MILTON HANKE

Bile pigment content of human traumatic hemorrhagic exudates. KURISHITA. *Klin. Wochschr.* 7, 1914(1928).—Hemorrhagic exudates contain considerably more bile pigment than does the circulating blood. This indicates that the pigments are produced locally.

MILTON HANKE

Guanidine studies. II. Distribution of guanidines in acute guanidine and parathyropriva tetanics. MAX MAPES ELLIS. Physiol. Inst., Univ. Glasgow. *Biochem. J.* 22, 930-6(1928); cf. *C. A.* 22, 2413.—The guanidine contents of the livers, kidneys and brains of animals in acute guanidine tetany (A) were high. Neither high blood guanidine nor high muscle guanidine is required to maintain (A). No storage of guanidine even equalling the av. tissue guanidine was observed. III. Water content of certain tissues during acute guanidine and parathyropriva tetanics (B). *Ibid* 937-40.—Brain, kidney and striated muscle from animals in (B) had higher water contents than the same tissues from normal control animals. Blood from rats in (A) had a lower water content than normal rat blood. IV. Changes in guanidine action and in parathyropriva tetany produced by dextrose. *Ibid* 22, 941-6.—Dextrose guanidine was less active than its equiv. of guanidine base. Combined injections of dextrose and guanidine carbonate were less toxic than injections of guanidine carbonate

alone. Dextrose and adrenaline injections relieved parathyroparivria tetany in cats.

BENJAMIN HARROW

The testing of sheep erythrocytes; observations upon lead poisoning in animals. HANS RUPP. *Arch. Hyg.* 99, 165-80(1928).—In sheep suffering from chronic poisoning, induced by the subcutaneous injection twice weekly of 5 mg. Pb (as $\text{Pb}(\text{NO}_3)_2$ soln.) per kg. body wt., there was noted an increase in the resistance of the erythrocytes to hypotonic salt solns., while specific hemolysis occurred more readily. The condition of the erythrocytes as well as their total no. is of significance in the Wassermann reaction.

P. Y. JACKSON

The formation of basophile granulated erythrocytes by exposure of animals to warmth and moisture; the significance of the granulated erythrocytes in the early diagnosis of lead poisoning. HANS LEHMANN. *Arch. Hyg.* 99, 181-95(1928).—Guinea pigs were kept in a specially designed app. at a temp. of 28° and a relative humidity of 97° for 8 hrs. daily on 6 or 7 consecutive days. Microscopic examn. of the blood showed that basophile granulated erythrocytes appeared, as in Pb poisoning. No toxic foreign substance was administered to the animals during the expt. Exposure to moisture and high temps. of subjects suspected of Pb poisoning may lead to errors in early diagnosis. A photographic method is described for the more accurate detn. of the no. of erythrocytes in a blood smear.

P. Y. JACKSON

Studies of experimentally induced infectious diseases. IV. Changes in serum proteins in experimental trypanosome-infection in rabbits; and the effect of "Bayer 205." ERNST WIECHMANN AND HERMANN HORSTER. *Deut. Arch. klin. Med.* 155, 177-85(1927).—Injection of trypanosome-infected blood into a rabbit is followed by an increase in blood globulin and a slight decrease in blood albumin. Twenty min. after the subcutaneous injection of 5 g. "Bayer 205" the blood was found to be no longer capable of infecting healthy mice; during the next few weeks the albumin rapidly but at an irregular rate approached its normal concn.; the globulin somewhat more slowly. No effect upon the blood proteins was observed when "Bayer 205" was injected into healthy rabbits.

P. Y. JACKSON

An investigation of the pepsin content of the gastric juice. FRANZ DELHOUGNE. *Deut. Arch. klin. Med.* 157, 299-308(1927).—Little pepsin is found in the juice secreted by a healthy stomach, unless food is given to stimulate secretion. The subcutaneous injection of histamine especially stimulates the secretion of pepsin, as well as production of HCl. The pepsin concn. varies widely during a secretion period, reaching its max. after about 40 min. The max. concn. of acid is usually reached after the pepsin concn. has begun to fall off. With ulcus ventriculi the pepsin content is usually considerably higher, and with ulcus duodeni slightly higher, but a sharp distinction could not be based upon this detn. alone. In ulcus duodeni, however, the pepsin concn. during a single secretion period varied widely. In some cases where the gastric juice contained a subnormal amt. of acid (gastritis, achylia, carcinoma, pernicious anemia) the pepsin concn. was very low; the extent of degenerative change in the mucous membrane of the stomach is indicated by the decreased secretion of pepsin. Cases which did not respond to histamine injection showed the lowest pepsin concn.; the pepsin was present in normal amts. in other cases, though it may have been without activity because of lack of acid. The pepsin detn., with the histamine and neutral red tests, is recommended for the differentiation of achylia.

P. Y. JACKSON

Metabolic investigations in tuberculosis. I. Tuberculosis and the acidity of the urine. P. MÜLLER AND H. QUINCKE. *Deut. Arch. klin. Med.* 158, 42-53(1928); cf. *C. A.* 22, 4166.—The majority of tuberculous patients when kept upon a normal diet had an acid urine, and a high phosphate index (mono-di-phosphate ratio); and the acidity was higher where the wasting of tissues had progressed further. Apparently the acidity was due to the decompn. of the protein of the tissues. The excretion of NH_3 averaged about 0.4 g per day, a normal value. When a salt-free diet was given the acidity of the urine increased; both p_{H} and the phosphate index are changed, but not the NH_3 excretion. (With a diet rich in minerals the urine reacted more acid in 3 cases, less acid in 3, and was unchanged in 1.) That the increased acidity observed upon a salt-free diet was not due to a more concd. urine was shown by the following expt.: for a 3-day period little water was given, and for the next 3 days much water, the diet being the same during both periods. The p_{H} and NH_3 content were the same, but the phosphate index was higher during the second period. II. Tuberculosis and the buffers of the blood. P. MÜLLER AND H. ANTHES. *Ibid* 54-61.—The alk. reserve was detd. for about 25 patients with tuberculosis of the lungs; and was found to lie within normal limits (53-72 vol. %) in all but 2 cases. These cases showed values of 49.4 and 43.3 vol. %, resp.; they were in the last stages of the disease. A decrease

in alk. reserve accompanies the progress of the disease, and is attributable to the acid decompn. products of body proteins. The CO_2 -binding power of the blood at different CO_2 pressures was found to be normal in 33 of 35 detns. The p_{H} of the blood was normal, 7.31–7.34. The alveolar CO_2 pressure was about 40 mm. Hg. The diet seemed to be without influence upon the acid-base equil. of the blood. III. Tuberculosis and chlorine metabolism. P. MÜLLER AND H. QUINCKE. *Ibid* 62–8.—There is little agreement in the results of previous investigators of the quantities of NaCl in the blood and tissues of tuberculous patients. Usually the NaCl of the serum is less than normal, and may fall below 0.5% even in light cases. Only 9 out of 30 cases showed a normal concn. of 0.560–0.600%. This points to a decreased NaCl content in the entire organism and suggests that NaCl should not be withdrawn from the diet of tuberculous patients.

P. Y. JACKSON

The influence of fat in the diet upon acetonuria and acidosis in diabetes; an investigation of diafat. K. HOESCH. *Deut. Arch. klin. Med.* 160, 128–58(1928).—Diafat is a triglyceride contg. 11–13 C atoms in the fatty acid chain; its characteristic taste is due to free acid. It was almost completely utilized in man; none appeared in the feces and only traces in the urine. The basal metabolic rate was increased by about 22% after a test meal contg. 50 g. diafat. No ketonuria or acidosis was observed, and there was a beneficial effect upon carbohydrate toleration in diabetes. Following a carbohydrate-free test meal contg. fat or diafat the blood sugar concn. was slightly lower when diafat was used. The addn. of butter to a meal contg. diafat caused acetonuria; addn. of protein did not.

P. Y. JACKSON

Paroxysmal hemoglobinuria from cold. FERDINAND HOFF AND RICHARD KELS. *Deut. Arch. klin. Med.* 160, 177–95(1928).—Clinical observations upon paroxysmal hemoglobinuria show a parallel rise and fall (constituting 2 distinct phases) in the curves for leucocyte no., body temp., blood pressure, alkali reserve, blood sugar and hemoglobin content of plasma and urine. The cholesterol and NaCl content of the blood show irregular variations but no subnormal values. A high hemoglobin content of the urine is accompanied by a smaller vol., and by smaller content of NaCl and of H ions.

P. Y. JACKSON

Observations in the function test of the island apparatus according to Depisch-Hasenöhr. E. KYLIN. *Deut. Arch. klin. Med.* 160, 348–60(1928).—To obtain consistent results it was necessary that the subjects be fed a standard diet for several days before the test. In normal persons the ingestion of 75–100 g. sugar in 750–1000 cc. H_2O caused a hyperglucemia of 120–182 mg. % (av. 143), the max. being reached in 30–75 min. (av. 52). In all cases this was followed by a hypoglucemia of 5–25 mg. % (av. 13). Diabetic subjects with hypertonia in most cases showed a hyperglucemia followed by a decrease to sub-initial values; in non-hypertonic diabetics, however, the blood sugar concn. remained in most cases above its former value. In some respects the concn. curve for normal persons lies between the curves for hypertonic and non-hypertonic diabetics. The max. increase is reached more rapidly in hypertonic than in normal subjects; more slowly in non-hypertonics. The decrease to subinitial values is more marked in hypertonic subjects, while sub-initial values are not reached in non-hypertonics. Usually the most severe cases showed the least decrease in the excess blood sugar.

P. Y. JACKSON

The lactic acid content of the blood. MAX HOCHREIN AND ROLF MEIER. *Deut. Arch. klin. Med.* 161, 59–83(1928).—In functional disease of the liver there was usually an increase in the blood lactic acid of the resting subject. Circulatory insufficiency also increased the resting concn. of lactic acid; this might be a secondary effect due to functional changes in the liver. A rise in lactic acid was frequently observed in endocarditis with fever, angina, nephritis and in convalescence from pneumonia and articular rheumatism. This may be due to a disturbance in the rate of metabolic exchange between the tissues and the blood.

P. Y. JACKSON

Hypertension and blood sugar. ERNST WIECHMANN. *Deut. Arch. klin. Med.* 161, 92–110(1928).—The whole blood of 19 hypertonic subjects showed an av. sugar content of 114 mg. %, the extreme concns. being 91 and 143 mg. %. However, there is no parallel between high-blood pressure and high-blood sugar. The ratio of erythrocyte-sugar to plasma-sugar is slightly lower (av. 92:100) in hypertonic than in normal subjects. Peroral administration of 100 g. glucose is followed, after 40–50 min., by an av. difference of only 21 mg. between the total quantities of sugar in 100 cc. of arterial and of venous blood; the permeability of the tissues to glucose may be greater in hypertonic subjects. The administration, at intervals, of glucose, or starchy food, upon an empty stomach, produces in hypertonics a step-wise increase in blood sugar. This reaction resembles that in diabetics.

P. Y. JACKSON

The role of the reticulo-endothelial system in iron metabolism. (The pathogenesis of chlorosis.) SAMUEL LEITES AND A. RIABOW. *Krankheitsforsch.* 4, 249-62 (1927).—A blockade of the reticulo-endothelial system of rabbits brings about a decrease in the Fe content of the blood, with little change in the no. of erythrocytes. Chronic blockade leads to a decrease in the erythrocyte no. In exptl. phenylhydrazine-anemia, however, the blockade with collargol not only does not increase the effect of the phenylhydrazine, but lessens that effect. Splenectomy has the same effect as collargol in checking the action of the phenylhydrazine. This effect of the blockade upon the development of anemia after treatment with phenylhydrazine can be ascribed to a lowering of the hemolytic function of the reticulo-endothelial elements of the spleen. The decrease in Fe content of the blood is due to a functional weakening of the Kupffer cells of the liver. Exptl. chlorosis could be brought about by means of the blockade; this is due especially to the effect upon the Kupffer cells. P. V. JACKSON

The titration of the antimeningococcic serums. ANDRZEJ BIERNACKI. *Med. Doswiadczenia i Społeczna* 7, 394-405 (Polish), 405-6 (French) (1927).—The titration of antimeningococci serums by flocculation with the alc. meningococcic exts. gives good results only with benzoic antigen. The exts. without addn. of lipoids and with addn. of cholesterol give inferior results. The flocculating antibodies and agglutinin are sep. antibodies. The flocculation reaction is specific for the genus of the microbe, not for the meningococcus group. JAROSLAV KUČERA

The antigenic properties of lipoids. Z. YERMOLYEVA. *Mikrobiol. Inst. des Kommissariats für Volksgesundheit, Moskau.* *Z. Immunitäts.* 57, 102-6 (1928). See C. A. 22, 2982. JULIAN H. LEWIS

Experimental and theoretical studies on the role of magnesium and calcium in the acidification or in fatiguing of muscles. Behavior of earthy phosphates of the muscle in acid or alkaline death rigor. LEONHARD WACKER. *Pathol. Inst. Univ. München, Biochem. Z.* 196, 426-40 (1928).—The ash content of intact muscles diminishes with the onset of death rigor. The decrease is greater in acid than in alc. rigor. The soln. components of the total ash actually increase during postmortem acid formation, and this involves chiefly the Mg and Ca phosphates. The conversion of the insol Mg into the sol. electrolyte state during the work of the muscle is supposed to be of physiol. significance: (1) The ionized Mg introduced parenterally produces a curare like paralysis, the amt. necessary for causing this narcotic effect being equal to the total amt. of Mg present in ionized and unionized form in the muscle. (2) Pathol. irritability and convulsive responses of muscles in tetanus and in tetany can be controlled with Mg. (3) This holds true also in exptl. tetany due to parathyroidectomy. (4) Tetany can be remedied by artificially produced acidosis (NH_4Cl or CaCl_2) which induces a rise in the Ca and Mg ions. The effect of fatigue is likewise thought to be due to the increase of Mg ions in muscles which have become acid due to exertion. S. MORGULIS

The quantitative distribution of gold in the organs of healthy and of tuberculous rabbits following treatment with gold preparations. I. Experiments on non-tuberculous rabbits. B. BRAHN AND G. WEILER. *Chem. Abt. städtisches Krankenhaus in Friedrichshain, Biochem. Z.* 197, 343-52 (1928).—The max. amt. of Au was either in the liver or in the kidneys depending on the particular prepn. used in the expt. The results for the other organs are very variable. S. MORGULIS

Alimentary glucemia in phlorhizin diabetes; a contribution to the phlorhizin effect on the liver. CARL SCHWARZ AND HELMUTH SASSLER. *Physiol. Inst. Tierärztliche Hochschule, Wien. Biochem. Z.* 198, 250-8 (1928).—Strong hypoglucemia occurs after prolonged phlorhizin action or starvation. On fasting days following phlorhizin days the blood sugar rises and in spite of fasting may attain normal values. The glycogen-forming and glycogen-storing function of the liver is disturbed even on days after the administration of phlorhizin, as can be judged from the 100% increase in the hyperglucemia resulting from carbohydrate rich food as compared to the similar reaction in normal dogs not treated with phlorhizin. S. MORGULIS

Studies on the physiological and pathological chemistry of the brain. III. The

lecithin of the brain. The phosphorus ether extractives of the brain from 6 cases of progressive paralysis were found to be increased per g. of substance; the N, expressed in percent of the dry substance, diminished. Furthermore, the choline N fraction, corresponding to the lecithin, was reduced to about $\frac{1}{3}$ of its normal value, while in other cases there was also a reduction in the NH_4N (the cephalin portion). Galactoside N could be demonstrated only in traces. The total N/choline N ratio changed from the normal value 1.4:1 to 3.1:1. This diminution in the lecithin, however, is not

pathognomonic for paralysis since it is also found in cachetic individuals, and should be considered rather a symptom of marasmus in general. S. M.

The clotting of fibrin as a process of micellar crystallization and agglutination. E. HEKMA. *Biochem. Z.* 199, 333-65(1928).—Thanks to the precipitin nature of thrombin the fibrinogen or the fibrinogen micellae are transformed into the labile pptd. condition, and the labile micellae place themselves end to end and form needle or thread-like crystals. This process would go on indefinitely if it were not opposed by the agglutinin action of the thrombin which imparts a stickiness to these crystals whether they are visible or invisible microscopically, so that they begin to form agglutinated masses. The thrombin is reversibly adsorbed by the micellar crystals. The agglutinin effect of the thrombin which acts to cement together these crystals is decidedly increased by Ca. The Ca is evidently transferred to the fibrinogen by the thrombin. Fibrin is thus an adsorption compd. of fibrinogen and thrombin. The nature of the fibrin is variable, from the point of view of its structure, compn. and properties, which depends upon the agglutinin action of the thrombin and upon the participation of the Ca. To the agglutinin component of the thrombin is attributable the contractility and the elasticity of the fibrin-gel, and to the Ca the degree of its irreversibility. The Ca must be removed from the compd. before the fibrinogen and the thrombin can return to the sol. state and sep. This also explains why the fibrin-gel is much more easily solvated reversibly in the presence of acid than of alk. This also makes it possible to interpret why thrombin had been regarded as an enzyme since this has so many points of similarity to the precipitins and agglutinins: no stoichiometric relation between the agent and the substrate; better progress of the reaction at body temp.; certain amt. of thermolability; influence of the milieu and especially of electrolytes; activating effect of Ca salts; the presence of antibodies and, last but not least, the property of the agent to become attached by adsorption to the substrate. Assuming that the secretion of an antithrombin by the living blood vessel lining is a firmly established fact, the fluidity of the circulating blood may be regarded as secured by 2 factors. First, the flowing blood is protected from evapn. and contact with rough surfaces and has a const. alkali reserve and OH-ion concn.; secondly, the inactivation of thrombin by the secreted antithrombin. In view of the established precipitin and agglutinin property of the thrombin the conception of an antithrombin as an anti-agglutinin and anti-precipitin finds confirmation in modern immunology. When blood flows outside the vessels all these factors at once disappear. The blood comes in contact with rough surfaces; this promotes the agglutination and destruction of platelets and also, to a certain extent, of leucocytes and even erythrocytes, and at the same time agglutinin and precipitin (*i. e.*, thrombin) becomes very active. Without a const. alk. reserve and without the antithrombin present the fibrinogen falls under the action of the thrombin. This is also the mechanism of the coagulation as it takes place in an isolated segment of a blood vessel; but where the blood flows over a cut surface there is the added effect of the evapn. which tends to form the firm crust and of the tissue coagulins. S. MORGULIS

Specific hemolysis. I. Specific adsorption of hemolysin and complement. KENICHI HORINO. *Med.-chem. Inst. Chiba. J. Biochem. (Japan)* 9, 407-21(1928).—Hemolysin is not adsorbed either by kaolin or by infusorial earth in a phosphate mixt., but at the acidity of a citrate buffer there seems to be some adsorption by kaolin, while infusorial earth completely adsorbs the hemolysins in a citrate-HCl mixt. of a proportion of 1:1 or 1:2. The adsorbed substance can be leached out with a mixt. of 16 cc. $M/7$ NaCl + 4 cc. $M/7$ K_2HPO_4 , showing that the adsorption is reversible. The complement is adsorbed by kaolin in a weakly alk. mixt. while at a slightly acid reaction by infusorial earth. The adsorption by kaolin is not reversible as in the case of the hemolysin. Likewise the leaching out of the infusorial earth adsorbate is not complete as the soln. obtained must be completed through the addn. of inactivated serum. It is assumed that the complement consists of 3 portions of which one is irreversibly adsorbed. II. Enzymes of the guinea-pig serum. *Ibid* 423-33.—Hemolysis is the result of the destruction of the colloidal structure of red cells and hence a study has been undertaken of the enzymes which might be instrumental in the hydrolysis of these complex mols., both the albumin and the globulin fractions of the serum being used. Expts. demonstrate that the enzymes found in guinea-pig serum, namely, protease, peptase, butyrase, lipase, lecithinase, amylase and nuclease are all present only in the albumin fraction. It is remarkable, however, that thrombin is largely in the globulin fraction, and in mere traces in the albumin. It was further found that a thrombin soln. possesses the properties of the mid piece of complement which it can replace. The albumin fraction, which can be obtained from a complement soln. to which lecithin has been added, has the same complement action as native serum. The adsorption and elution behavior

of this lecithin-albumin fraction is also similar to that of native complement. The thrombin distribution between the albumin and globulin fractions treated with lecithin follows the distribution of the complement middle piece. This is interpreted to mean that the lecithin so affects this substance that it can no longer be pptd. with CO_2 . This hypothesis was further corroborated by the exp^t where lecithin was added to the previously isolated globulin fraction when it is found that the complement mid piece could no longer be pptd. with CO_2 . Thrombin and the complement mid piece are thus mutually replaceable, and both are inactivated by heating 30 min. at 56° . In the globulin fraction of complement there is present a substance which takes part as mid piece in the process of hemolysis and as thrombin in the process of blood coagulation. III. Gysinogen of erythrocytes and its new reactions. *Ibid* 435-44.—A water ext. of goat red blood cells freed from stromata becomes turbid when treated to $1/2$ satn. with NaCl, or on passing CO_2 . The fibrinogen-like substance was prepd. free from hemoglobin by pptg. first with a current of CO_2 and, after centrifuging, dissolving the residue in physiol. NaCl soln. Repeating this process several times yielded a colorless substance. The NaCl must be Ca-free or else the fibrinogen yield is greatly diminished. This soln. is pptd. by $1/2$ satn. with NaCl but not by complement or by its globulin fraction. If this soln. is treated first with hemolysin and complement it no longer gives a turbidity upon the $1/2$ satn. with NaCl. The soln. did not remain clear if any one component (hemolysin, albumin or globulin fraction of complement) was omitted. In other words, the substance extd. from the red cells was rendered unprecipitable with NaCl by hemolysin + complement, so that it must have undergone a change in the direction of increased dispersion. Similar results were obtained when the complement was adsorbed by alumina and then leached out. As with fibrinogen the lecithin-albumin fraction acts as the complement for the specific hemolysin in the fibrinogen-like substance of the red cells. Likewise, the thrombin soln. could replace the globulin fraction of the complement. Rabbits were immunized with this fibrinogen-like substance obtained from goat red cells. An immune serum was prepd. as usual and this was heated 30 min. at 56° . This had a very high hemolytic titer, 1:40000 diln. producing extensive hemolysis. It was entirely non-hemolytic with rabbit cells, but did have some effect on sheep and beef cells. Conclusion: the erythrocyte fibrinogen-like substance is a lysinogen.

S. MORGULIS

The problem of anaphylaxis in cold-blooded animals. Z. MICHAILOVA AND F. KAVENOKII. Chem. Lab., State Polytech. Museum, Moskow. *Zhurnal exp^t. Biol. Med.* 9, 361(1928).—Frogs cannot be used for the study of anaphylaxis S. M.

Anaphylaxis in frogs. I. F. LEONTYEV. Chem. Lab., State Polytechnic Museum, Moscow. *Zhurnal exp^t. Biol. Med.* 9, 367-8(1928).—It is not possible to call forth an anaphylactic reaction in frogs. S. MORGULIS

Glucemia in experimental hydrophobia. BORIS KOLDAYEV. Bact. Inst. Kiev. *Zhurnal exp^t. Biol. Med.* 9, 370-4(1928).—Hydrophobia caused by means of injections of the fixed virus is not accompanied by any definite changes in the blood sugar. The blood obtained after death from the heart showed in most cases a distinct rise in sugar content (about 66%) accompanied by an increased amt. of reducing substance in the urine. S. MORGULIS

Hydrogen-ion concentration of the blood in diseases of myeloid and lymphoid tissues. V. VARSHAVSKII AND V. KRAINSKA-IGNATOVA. Ukraina Röntgen and Radium Inst., Charkow. *Zhurnal exp^t. Biol. Med.* 9, 432-6(1928).—There was no change in the blood p_H . Considerable variations were noted in the titratable alkali. S. MORGULIS

The catalase content of erythrocytes in experimental anemia. V. S. SUMBAYEV. Lab. pathol. Physiol. State Univ., Saratow. *Zhurnal exp^t. Biol. Med.* 10, 9-17(1928).—When oxalated rabbit blood is centrifuged it is possible to sep. 2 layers of erythrocytes with different catalase indices. Generally, the upper layer is richer in polychromatophiles and also has a higher catalase content than the lower layer. In anemia produced by means of phenylhydrazine the upper layer is much richer in polychromatophiles and also its catalase is decidedly greater than that of the lower layer. In the period, however, of the rapid increase in the erythrocytes the lower layer is as active as the upper layer catalytically, but the no. of polychromatophile cells at that time is actually much reduced. The normal catalase distribution is restored when the morphological make up of the blood has become normal again. In post-hemorrhagic exp^t. anemia the upper layer of cells has more polychromatophile cells and more catalase than the lower layer as long as the anemia lasts. The young polychromatophile cells have a lower sp. gr. than old cells. The increase in the catalase index of anemia blood is ascribed to the fact that the blood is younger. S. MORGULIS

Calcium and sympathetic nerve activities. E. GLEY. *Arch. sci. biol.* (Italy) 12, 39-49(1928).—The diminution of Ca in the blood and the immobilization of the Ca ions det. not only the suspension of the cardio-inhibitory action of the pneumogastric, but also the suspension or enfeeblement of the cardio-accelerator action of the sympathetic and vaso-constrictor, vaso-dilator and secretory actions of the secretory nerves. Whether these nerves belong to the para-sympathetic or proper sympathetic system is not important. The activity of the nerves in each system depends on the same chem. condition, since they are equally affected by a lack of Ca. L. W. RIGGS

Action of acridine derivatives on blood sugar. O. J. NIELSEN. *Bibliotek for Laeger* 120, 481(1928); *J. Am. Med. Assoc.* 91, 1000.—Following the injections of an acridine deriv., no particular fall in blood-sugar values was noted in nondiabetics. In fasting diabetics more or less marked decrease in the blood sugar values occurred, but often no greater than in fasting diabetics without injection. No definite conclusion was reached in diabetics with simultaneous intake of food. Further work is in progress. L. W. RIGGS

Nature of pernicious anemia in light of the newer knowledge. J. H. MEANS AND WYMAN RICHARDSON. *J. Am. Med. Assoc.* 91, 923-5(1928); cf. following abstr.—Pernicious anemia is a chronic disease of unknown etiology, the chief manifestations of which can be held in abeyance so long as adequate amts. of a sp. substance contained abundantly in liver and kidney are received. Shortage of the sp. substance is responsible for the abnormalities in the marrow and the blood. The cause of the shortage is not completely known. Castel's work suggests that the gastric defect may play an important role. Whether the normal human requires any extraneous supply of the sp. substance or can synthesize what he needs is not yet known. Whether the active substance now found is in the state that the body needs or is merely a necessary building stone has not been detd. L. W. RIGGS

Treatment of pernicious anemia with liver and liver extract. THOMAS ORDWAY AND L. W. GORHAM. *J. Am. Med. Assoc.* 91, 925-8(1928); cf. following abstr.—This study adds 25 cases to the 553 carefully detailed in the literature. Strict adherence to the original Minot and Murphy diet is not essential. A balanced, liberal, general diet plus sufficient liver is equally effective. The administration of dil. HCl is unnecessary. Liver appears to exert a sp. influence on the development of faulty red blood cells. It has no effect on the underlying pathologic process and hence cannot be called a cure. The quantity of liver eaten should be from 0.25 to 0.5 lb. daily. It may be given raw, cooked or as a potent ext. The amt. of liver administered varies with the patient and the progress of the disease as detd. by periodical blood counts. Accurate diagnosis is vitally necessary before the use of the liver diet. Transfusion is of value in desperate cases in which the blood count is below a million. It should be used to tide over a desperately ill patient, so that he may later take the liver diet. L. W. R.

Pernicious anemia treated with liver diet and liver extract. ELMER H. HEATH. *J. Am. Med. Assoc.* 91, 928-32(1928); cf. preceding abstracts.—Careful reports of 19 cases of pernicious anemia treated by liver diet and of 5 cases treated by liver ext. are given. Excellent results were obtained in all of the cases. L. W. RIGGS

The erythropoietic response of the various anemias to liver therapy. WM. S. MIDDLETON. Univ. Wisconsin. *J. Am. Med. Assoc.* 91, 857-63(1928); cf. following abstr.—A study of 32 cases gave addnl. confirmation of the sp. value of liver and liver ext. in pernicious anemia. Of 40 patients with secondary anemia, 14 responded favorably to the dietary regimen of Minot and Murphy. This response was apparently not to the sp. maturing factor in liver, since no reticulocyte showers comparable to those in the remission of pernicious anemia occurred on the diet. The use of liver treatment in secondary anemia is still an exptl. problem. The indiscriminate use of liver in all types of anemia should be discouraged, since it creates an economic burden for patients with pernicious anemia. Cu does not appear to be the active agent in remissions in pernicious anemia. L. W. RIGGS

Experimental anemias, diet factors and related pathologic changes of human anemias. G. H. WHIPPLE. Univ. Rochester. *J. Am. Med. Assoc.* 91, 863-7(1928); cf. following abstr.—Diet factors are listed as to their potency to cause new blood hemoglobin regeneration in severe long-continued anemia due to bleeding in dogs. Liver stands first. Representing liver by 100, kidney is about 90, apricots 40, peaches 40, prunes 35 and apples 35. Tests of liver exts. point to a group of active substances rather than a single active principle. Fe may be inactive in some anemias and potent in others. Inorg. elements are potent in anemia. Some elements are potent in one type and not in another. The ashes of apricots, liver and kidney are potent in secondary anemias due to bleeding. Conservation of injected hemoglobin was about 90%,

while by mouth 10%. Pernicious anemia is a deficiency disease and not the result of an obscure poison. L. W. RIGGS

Liver fractions in pernicious anemia. RANDOLPH WEST AND EMILY G. NICHOLS. Columbia Univ. *J. Am. Med. Assoc.* 91, 867-8(1928); cf. following abstr.—Various fractions were made from liver ext. 343 of Eli Lilly Co., and these exts. were tested for their efficiency in increasing the erythrocyte and reticulocyte counts in pernicious anemia. The best fractions prepd. from 343 contained N 12 to 14%, and amino N 20% of the total N. This amino N increases to about 40% after acid hydrolysis. S was present in traces. P and Fe were absent. The fractions gave + reactions in the biuret, diazo and naphthol tests, a weak + Hopkins-Cole reaction and a slight levorotation. L. W. RIGGS

Influence of fever on the tissue sugar metabolism in the liver. HARUYOSHI IWA-SAWA. *Proc. Imp. Acad. Tokyo* 4, 425-6(1928).—Sugar metabolism, particularly the glycogen synthesis of the liver, in spite of increased O consumption undergoes in fever a certain disturbance, in that the anaerobic splitting of glucose into lactic acid is diminished. L. W. RIGGS

Cytochrome in tumor tissues. HIDETAKE YAOI, HIROSHI TAMURA AND WARO NAKAHARA. *Proc. Imp. Acad. Tokyo* 4, 433-5(1928).—Fujinawa rat sarcoma contains a large amt. of cytochrome; Flexner-Jobling rat sarcoma and Bashford mouse carcinoma contains a medium amt.; and Rous chicken sarcoma contains either little or none of this respiratory pigment. It is probable that these facts can be correlated with the difference in the ability of different types of tumors to withstand the deprivation of O. L. W. R.

Effect of anoxymbiosis upon the phosphate excretion of surviving tumor tissues. HERMANN LANGE AND NORBERT HENNING. Univ. Leipzig. *Arch. exp. Path. Pharm.* 134, 105-8(1928).—Because tumor tissues undergo an increased cell permeability under anoxymbiotic conditions the yield in phosphate is increased. G. H. S.

Postmortem increase in the lactic acid of the brain in experimental animals. M. E. MAYER. Univ. Frankfurt a. M. *Arch. exp. Path. Pharm.* 134, 218-24(1928).—The increase in acid in the gray matter of the brains of dogs and calves was definitely greater than in the white substance, e. g., during the period of 1 hr. the increase was 38% in the gray, and 18.4% in the white substance. A postmortem increase in lactic acid could be observed in the brain of cats, even though through operative procedure an anemia of the brain had been previously established. G. H. S.

Blood cholesterol studies in cancer. II. With investigation as to possible diagnostic relations. W. L. MATTICK AND KENNETH BUCHWALD. State Inst. Malig. Dis., Buffalo, N. Y. *J. Cancer Res.* 12, 236-45(1928); cf. following abstract.—The cholesterol content is higher in plasma blood than in whole blood in 85% of cancer patients, and also in cancerous mice. In 80% of normal individuals, and in normal mice, the cholesterol content is higher than in the whole blood. Diagnostic possibilities are suggested. H. G. WELLS

Blood cholesterol studies in cancer. III. Relation to nonmalignant conditions. WALTER L. MATTICK AND KENNETH BUCHWALD. *J. Am. Med. Assoc.* 91, 1087-90(1928); cf. preceding abstract.—Blood cholesterol values and ratios of the relation of plasma and whole blood cholesterol are reported in 20 healthy, 101 cancerous and 75 non-cancerous patients ill with various diseases. A plasma whole blood cholesterol ratio greater than 1 was found in 86% of the cancer cases. This disturbed ratio is probably a fairly const. finding in cancer. A plasma whole blood cholesterol ratio of less than 1 was the usual finding in 80% or more of the healthy. In noncancerous diseases this ratio was in accordance with that in health in 67%, whereas in 33% it was reversed and was as in cancer. This reversal may be accounted for on the basis of a temporary derangement of this ratio by some noncancerous disease. L. W. RIGGS

The physical chemistry of cancer. N. WATKMAN. *Z. Krebsforsch.* 27, 228-40(1928).—In part a review of some expts. with normal and cancerous tissues in which W. discusses the effects of various ions, especially Ca, on the polarization resistance const. of the cell membrane. The method is illustrated and described. The H-ion concn. of the medium affects the preservation and suspension of normal and cancerous tissue cultures. While cancerous tissue cultures *in vitro* have been found to be preserved satisfactorily at a pH 7.0-7.8, W. finds that isolated and washed cancerous cells can be kept best at pH 5.4. X-rays produce a pos. effect upon the polarization resistance const. of normal tissue but a neg. effect upon cancerous tissues because of the presence and counteracting influence of lymphocytes. Ca ions increase the const. Other data given are similar to those of other workers such as Gaspari, Centanni and Fibiger. H. G. WELLS

Cholates and tumor growth. V. E. MERTENS. *Chirurg. Klin. Munich. Z. Krebsforsch.* 27, 295-307(1928).—The theory that reduction in surface tension is a factor in producing tumor growth could not be established as a general principle. Treatment with cholates did not stimulate the growth of tar cancers and spontaneous tumors in mice. In rabbits, Na cholate inhibited tumor growth. Sometimes Na cholate causes formation of dense fibrous tissue. H. G. WELLS

Investigation of agents that produce cancer. C. C. TWORT AND H. R. ING. *Lab. of Cancer Com., Manchester, Eng. Z. Krebsforsch.* 27, 308-51(1928).—An extensive investigation of various substances that produce cancer in man and exptl. animals. Of several oils tried, whale oil was harmless, petroleums are slightly dangerous, while shale oil ranks with gas tars as likely to produce cancer. The cancer-producing activity of shale oil is about 12 times as great as that for petroleum. Two petroleum oils used in cotton spinning mills were tested, and the high-boiling fractions were about 31 times more active than the lower fractions. On the contrary, with shale oil the low-boiling fractions were most active. Some oils lose their activity if treated with H_2SO_4 , and some inactivation was obtained by oxidation and reduction. An especially active tar was obtained from pinene and turpentine by dry distn., most of the toxic components distg. over at 3 mm. pressure between 200 and 300°, and being extractable with cold C_2H_5OH . An artificial mixt. of aromatic derivs. was cancerogenic. All the tumors obtained were of epithelial origin, although some looked somewhat like sarcomas. Probably the cancer-producing substance is an unsatd. hydrocarbon or an aromatic compd. H. G. WELLS

Surface tension of sera as affected by the precipitin reaction. SUSAN GRIFFITH RAMSDELL. *Research Inst. Cutaneous Medicine, Philadelphia. J. Exptl. Med.* 48, 615-7(1928).—An attempt to find evidence, through the study of surface tension, using the du Nouy tensiometer, of a denaturing effect of the precipitin reaction upon either the antigen or the immune serum, yielded entirely neg. results. C. J. WEST

II—PHARMACOLOGY

A. N. RICHARDS

Report on the results of examination of nine cases after the oral ingestion of 1000 grams of glucose. W. J. MAY. *Brit. Med. J.* No. 3522, 7-8(1928).—Oral ingestion of 1000 g. of glucose caused hyperglucemia and glucosuria in 5 cases, but in 4 cases normal blood sugar was accompanied by glucosuria varying from a trace to 2%. J. B. BROWN

Some observations on the effect of blueberry-leaf extract in diabetes mellitus. E. M. WATSON. *Univ. Western Ont., London, Ont. Can. Med. Assoc. J.* 19, 166-71(1928).—This ext. appears to exert a beneficial effect in certain cases but its action is not consistent. Its utility is most apparent in middle-aged or elderly patients and in mild cases; it is of no avail in the emergencies of the condition. It does not give rise to serious hypogluccemia. It may become an adjunct but cannot be regarded as a substitute for insulin. A. T. CAMERON

The use of thiocyanate of soda in high-blood pressure. ARTHUR G. SMITH AND R. D. RUDOLF. *Can. Med. Assoc. J.* 19, 288-92(1928).—Sodium thiocyanate produces a fall in blood pressure, with usually no change in heart rate, the best results being obtained in cases of "essential hyperpiesis." A. T. CAMERON

The pre-operative treatment of Graves' disease by a combination of iodized fatty acid and vitamins A and D. GILBERT I. ADAMSON AND A. T. CAMERON. *Univ. Manitoba, Winnipeg. Can. Med. Assoc. J.* 19, 420-6(1928).—"Vitiodum," a combination of vitamins A and D and iodized jecoleic acid, is as effective as Lugol's soln. when administered in Graves' disease, its beneficial action, and the limits of that action, closely resembling those of Lugol's soln. It is probable that neither the vitamins nor the iodo-fatty acid alone are effective, though tests on a larger no. of cases are necessary to settle this point. The results suggest the desirability of investigating as widely as possible the relation between these vitamins and thyroid and I metabolism. A. T. CAMERON

The action on nerve and muscle of pyridine compounds. L. DE CARO. *Arch. intern. physiol.* 29, 163-74(1927); *Physiol. Abstracts* 13, 117-8.—The effect of the administration of pyridine compds. in Ringer soln. by the dorsal lymph sac on the chronaxie of the gastrocnemius muscle and the sciatic nerve of the frog was studied. The hydrogenation of the pyridine mol. caused an increase in the toxicity for muscle and for nerve. When the benzene nucleus was added, the compd. was much more toxic for nerve. The methylated compd. had greater toxicity for muscle and a decreased toxicity for nerve. H. J. DEUEL, JR.

Insulin reactions. HENRY J. JOHN. Cleveland Clinic Foundation. *J. Metabolic Research* 7-8, 51-8(1925-6).—The blood sugar apparently is not the prime cause for the insulin reaction since this occurs sometimes at relatively high levels of the blood sugar while no reaction may be obtained when insulin is injected into the same individual with the original blood sugar at a considerably lower level. H. J. DRUEL, JR.

The action of sodium chloride on normal, pregnant and partially nephrectomized animals. I. Chlorine and water metabolism. HARRY LUNDIN AND RUDOLPH SCHARF. Physiatrie Inst. Morristown, N. J. *J. Metabolic Research* 7-8, 259-326(1925-6).—Expts. on a normal (A), 2 partially nephrectomized (B), and a pregnant sheep (C). The administration of large amts. of NaCl to A resulted in a comparatively low retention of this salt, while a greater amt. was retained by B and a still larger amt. by C. Following partial nephrectomy (B) there was an inability of the kidney to conc. the urine after the administration of huge doses of NaCl (40 g.). However, these animals still possessed the ability to excrete large amts. of H₂O as well as a large quantity of the NaCl, the lower urine concn. being compensated by the largely increased vol. With A, a max. concn. of 2.76% of NaCl occurred in the urine, while in C the av. and max. NaCl concn. was less than in the normal non-pregnant animal. The H₂O retention per g. NaCl retained was much higher in C than in A or B. Under the same conditions the H₂O excretion through the lungs averaged the same in the 4 animals. With an increase in H₂O metabolism a greater excretion through the lungs occurred. After the administration of NaCl to B, a decreased H₂O elimination through the lungs occurred because of the need of increased H₂O for formation of urine. In uremia due to partial nephrectomy an increased ventilation occurred with an increased H₂O elimination through the lungs. Overventilation may act as one of the compensatory mechanisms in water metabolism. Immediately following the high salt diet there is a fall in urine vol. The sp. gr. of the urine in B for the 2 days following the omission of the salt was unusually low, suggesting that the kidney remnant cannot adapt itself for concn. of the nitrogenous products. after the sudden cessation of the functional overstrain. II. Influence of sodium chloride on the inorganic constituents of the blood. RUDOLPH SCHARF AND HARRY LUNDIN. *Ibid* 327-55.—The exptl. conditions were the same as in the previous paper. The daily administration of large amts. of NaCl resulted in a considerable increase (18.9-43.9%) in the concn. of the cations (Na, K, Ca and Mg) while there was only a slight rise (1.0-5.8%) in the anion concn. (Cl, HCO₃, HPO₄, H₂PO₄). The blood was drawn 24 hrs. after the last salt feeding. The increase in the cations must therefore be compensated by other anions, presumably the neg. radicals of org. acids. An increase in the lactic acid and pyruvic acid excretion to a max. per day of 1.3 g. for the former and 3.7 g. for the latter during the salt feedings suggests this. The K ion shows the largest increase in the blood after the NaCl feeding although there was a greater concn. of all cations. The $\text{Na}^+ + \text{K}^+/\text{Ca}^{++} + \text{Mg}^{++}$ ratio, which normally is 28, varied only slightly; the increase in the Na and K is balanced by a parallel rise in Ca and Mg. The Cl⁻ showed a remarkable constancy after NaCl feeding with a max. increase of only 9%. No change in the HCO₃⁻ concn. occurred while the phosphate was almost doubled in some cases. After the partial nephrectomy with uremia in one of the animals different results were obtained. There is therefore an independence in the excretion of Na and Cl. In the normal, as well as one of the nephrectomized and the pregnant, animals, the rise in Na occurred without an increase in the blood Cl while in the uremic animal the rise in Cl occurred first while an increase in the Na occurred later.

Plant extracts with an insulin action. II. The effect of bean husks on diabetes. E. KAUFMANN. Univ. Köln. *Z. ges. expil. Med.* 55, 1-12(1927).—In fasting rabbits water and alc. exts. lowered the blood sugar, as well as diminished the hyperglucemia following glucose injections. Similar results were obtained in diabetics though the results were not as marked as with insulin.

F. L. DUNN

Can a form of slow potassium cyanide poisoning result from a massive per oral dose? WALTER ERNST. Landesanstalt für epileptische Hochweitzschen, Saxony. *Deut. med. Wochschr.* 54, 1373-4(1928).—A case is reported in which a patient's death occurred 2 weeks after a massive dose of KCN.

ARTHUR GROLLMAN

The resorption of mercury after the application of precipitated white mercury

salve to the skin. G. MALOFF. Univ. of Berlin. *Deut. med. Wochschr.* 54, 1381 (1928).—Only small quantities of Hg were absorbed after the application of a 5% salve to the skin. ARTHUR GROLLMAN

The phosgene poisoning catastrophe in Hamburg. I. Clinical observations. C. HEGLER. Krankenhaus St. Georg, Hamburg. *Deut. med. Wochschr.* 54, 1551-3 (1928).—A description of the clinical manifestations shown by the victims of the explosion of a tank contg. 11 tons of phosgene, in Hamburg on May 20, 1928. II. Pathological anatomy of the phosgene poisoning. FRIEDRICH WOHLWIEL. *Ibid* 1553-7.—The chief pathological effects of phosgene poisoning are manifested in the upper respiratory tract, the bronchi, pulmonary tissues and the blood-vessel walls. Edema, interstitial inflammation, stasis, thrombosis with embolus formation, and degenerative changes in the nerves were the predominant sequelae. III. The formation of blood pigments by phosgene. HERMAN MAYER. Univ. of Hamburg. *Ibid* 1557-8.—The formation of hematin in the blood after phosgene poisoning is attributed to the action of the HCl which is liberated by the hydrolysis of the phosgene. ARTHUR GROLLMAN

The physiological response of rabbits to insulin. MELVILLE SAHYUN AND N. R. BLATHERWICK. Santa Barbara Cottage Hospital. *J. Biol. Chem.* 79, 443-60(1928).—The convulsive dose of insulin was higher when administered intravenously than when administered subcutaneously or intraperitoneally while the time necessary to produce convulsions was less in the former case than in the latter. Adrenaline injected 24 hrs. before insulin administration increased the sensitivity of the animals to the latter substance. Splenectomized rabbits were very sensitive to insulin and such animals are suggested for use in the assay of insulin. Immunity to insulin was developed to a marked degree in rabbits maintained on a high carbohydrate diet. Blood sugar curves of such animals after the injection of large doses of insulin are given. A. G.

Dihydroxyacetone and insulin hypoglycemia. P. A. LEVENE AND J. G. BLANCO. Rockefeller Inst. *J. Biol. Chem.* 79, 637-66(1928).—The effect of pure monomeric dihydroxyacetone on insulin hypoglycemia in rabbits was studied by following the concn. of dihydroxyacetone and sugar in the blood during the exptl. period. Both subcutaneous and intravenous administrations of dihydroxyacetone were often followed by temporary recovery from the symptoms of hypoglycemia. In such cases there was a rise in the concn. of glucose in the blood and in all cases, but one, hydroxyacetone was also present in the blood. The expts. indicated that in the presence of an excess of insulin, dihydroxyacetone is not converted into glucose to a very large extent. ARTHUR GROLLMAN

The effect of atropine upon the output of the hearts of normal men. W. CARTER SMITH, C. S. BURWELL AND M. G. DEVITO. Vanderbilt Univ. *J. Clin. Investigation* 6, 237-45(1928).—Atropine administered intravenously to normal men produced a marked rise in pulse rate, a relatively small rise in cardiac output and no change in pulse pressure or metabolic rate. ARTHUR GROLLMAN

The gaseous exchange following the administration of dihydroxyacetone. WALTER R. CAMPBELL AND S. SOSKIN. Univ. of Toronto. *J. Clin. Investigation* 6, 291-302 (1928).—Differences in R. Q., O intake, and CO₂ elimination occur when a normal animal is fed with dihydroxyacetone, as compared to the same animal given glucose. While depancreatized animals also show a rise in O and CO₂ elimination, the R. Q. remains low and the animal excretes the triose as glucose. These changes are temporary and are inconsistent with the explanation that fat is being produced or that large quantities of triose are being burned. Hyperventilation is suggested as a cause of the results obtained. ARTHUR GROLLMAN

The significance of respiratory quotients after administration of certain carbohydrates. WALTER R. CAMPBELL AND E. J. MALTBY. Univ. of Toronto. *J. Clin. Investigation* 6, 303-17(1928).—Dihydroxyacetone, fructose and cane sugar cause a lowering of the CO₂-combining power and a rise in the blood lactic acid, while glucose, maltose, lactose, galactose and glycerol do not. These changes take place at the proper time to cause stimulation of respiration. The increased elimination of CO₂ noted when such substances are fed explains the extraordinarily high CO₂-O₂ ratios found. Such ratios cannot be used as an index of food transformation, combustion, or storage of the first substances mentioned. These factors do not, however, interfere in the use of the ratios, as R. Q., in the other sugars examd. In view of the addnl. energy required, because of the stimulation of respiration and that lost by conversion of glycogen to lactic acid, the first-named sugars are not regarded as being more valuable in the treatment of diabetes than glucose itself. ARTHUR GROLLMAN

Tolysin in subacute rheumatic carditis. F. D. W. LUKENS. Penn. and Children's Heart Hospitals, Phil. *J. Clin. Investigation* 6, 319-24(1928).—Tolysin (Et p-tolyl-

cinchoninate) has no effect on the infectious process, in subacute rheumatic heart disease in children, as measured by the fever, wt. and leucocytosis. No toxic action was noted in any of the cases studied.

ARTHUR GROLLMAN

The influence of heavy metals on the growth of mouse tumors with particular reference to lead preparations. M. KOCHMANN WITH ILSE PARTAU. Friedrichs Univ., Halle-Wittenberg. *Klin. Wochschr.* 7, 1646(1928).—The action of a no. of Pb preps., $\text{Hg}(\text{CN})_2$, As_2O_3 and colloidal gold was tried on tumor mice. The results were not very encouraging.

MILTON HANKE

The mechanism of the action of synthalin. FERDINAND BERTRAM. *Deut. Arch. klin. Med.* 158, 76-97(1928).—Synthalin was used in the treatment of 21 diabetics with varying results. In light cases there was in most cases at first a marked effect upon hyperglucemia and glucosuria; but after continued use the substance lost its efficiency and there appeared such symptoms as loss of appetite, loss of wt., sleeplessness, fatigue, profuse sweat, etc. In some cases there were serious metabolic effects; and the usual amts. of insulin were not sufficient to restore the original equil. Some cases of medium intensity were transformed into serious cases by the loss of tolerance through the effect of synthalin. In more serious cases not even a temporary favorable effect was observed. A severe hyperglucemia in some cases followed the administration of moderately small doses and in 3 cases a precomatose condition resulted. Very large doses of insulin were required in the more serious cases to restore equil. The action of synthalin in lowering the concn. of blood sugar may be overcome by the administration of a sufficient quantity of atropine. Insulin, by producing a condition of rest, allows a diseased pancreas, at least in some cases and temporarily, to recover. On the other hand synthalin excites the pancreas to give up its last insulin reserve; and the more advanced the disease the sooner is the pancreas exhausted.

P. Y. JACKSON

Clinical studies on high arterial pressure and its response to therapeutic influences. E. FIRNBACHER. *Deut. Arch. klin. Med.* 161, 1-17(1928).—Br and I derivs., rhodapurine, diuretin, desencin, nitro derivs., grape sugar, etc., brought about only a temporary decrease in the blood pressure of resting patients. Desencin in doses of 0.5 g. 3 or 4 times daily produced the best results, without any accompanying dyspeptic or general toxic disturbances. A 0.5 g. dose was without any particular effect upon the blood pressure of a normal individual.

P. Y. JACKSON

Observations upon rabbits treated with cholesterol. OTTO DECKE. *Krankheitsforsch.* 3, 399-418(1926).—Cholesterol dissolved in olive oil, or in dry horse liver, was fed to a group of 88 rabbits; 56 of them showed a rise in blood pressure and in the cholesterol content of the blood; after several months the blood pressure returned to normal and there were no objectionable symptoms. A second group, 17 animals, suffered from cholesterol sickness. There was little or no increase in blood pressure, but a very sharp rise in cholesterol in the blood serum. The blood pressure gradually fell without any decrease in cholesterol concn., and with general symptoms of illness. The third group (13 animals) was scarcely affected with either increase in blood pressure, or with any change in cholesterol concn. All 3 groups showed after a time a cholesteatosis of the internal organs; this condition must be distinguished from hypercholesterolemia since it occurred with no increase in blood cholesterol. After a single intravenous injection of cholesterol there was a temporary increase in blood cholesterol; repeated injections caused irregular increases in the concn. of cholesterol in the blood; and sometimes the concn. returned to normal only some time after the end of the expt. Parenteral administration of cholesterol has less effect in raising the blood pressure and causes less cholesteatosis than enteral administration, even though a noticeable hypercholesterolemia is produced.

P. Y. JACKSON

Experiences with intarvin in diabetes mellitus. MAX EINHORN AND W. BRAUNSTEIN. Lenox Hill Hospital. *Arch. Verdauungs-Krankh.* 43, 120-7(1928).—In 7 of 10 cases of mild acidosis, the urine was freed of acetone bodies by feeding intarvin in amts. equiv. to the natural fat usually added to the diet. Intarvin is not injurious and produces no ill effects.

FRANCES KRASNOW

Intradermal sensitization for ipecac powder. PAWEŁ BAUMRITTER. *Med. Doswiadczenia i Społeczna* 7, 415-9(Polish), 419(French)(1927).—A sensitization of an individual insensitive to ipecac was obtained by the simultaneous intradermal injection of infusion of ipecac and of serum of the pig. The sep. injection of either of these substances alone did not lead to sensitization. Thus provoked sensibility is limited only to the skin.

JAROSLAV KUČERA

Toxic action of alkyl compounds of mercury. J. V. SUPNIEWSKI. *Med. Doswiadczenia i Społeczna* 8, 348-52(Polish), 353 (French)(1928).—The alkyl compds. of Hg such as $\text{Hg}(\text{CH}_3)_2$, $\text{Hg}(\text{C}_2\text{H}_5)_2$, $\text{Hg}(\text{C}_4\text{H}_9)_2$ have strong narcotic and diuretic proper-

ties because of their alkyl groups. Their late toxicity depending on the free Hg is shown as Hg encephalopathy accompanied by renal and intestinal lesions. The function of cardiac, voluntary and involuntary muscles and the respiration is depressed. J. K.

Studies on the pharmacological action of sea water. I. The toxicity of sea water introduced intravenously. ANGELO RABBENO. *Arch. sci. biol.* (Italy) 12, 469-77(1928).—Sea water from Trieste was filtered and injected into the jugular veins of rabbits until the animals died. The rate of injection varied from 0.5 to 5.0 cc. per min. By plotting the rate as abscissas and the dose as ordinates a curve was obtained which showed an initial peak with low rate of injection (0.5); then the curve dropped until it reached a primary min. at 1.5 rose and reached a secondary max. at 2.15, dropped to a secondary min. at 3.2, and again rose to a third and greatest peak at 5.0. The shape of the curve indicates that the factors of toxicity are of a different order and of opposite action. PETER MASUCCI

Experimental studies on the influence of peroral and intravenous administration of radium bromide on the urinary carbon:nitrogen quotient. A. ALLEN GOLDBLOOM. Patholog. Inst. Univ., Berlin. *Biochem. Z.* 197, 14-9(1928).—Repeated daily peroral administration of RaBr₂ in 400 M.-E. doses per kg. causes in rabbits a very definite rise in the urinary C:N quotient due to the limitation of the N excretion. A single intravenous injection of a 1100 M.-E. dose causes a gradual rise in the quotient which likewise depends upon the diminution in N elimination. Like radiothorium, the RaBr₂ therefore also produces a reduction in the metabolic process. S. MORGULIS

Studies on tissue respiration. IV. Influence of thyroxine, adrenaline and insulin on the oxygen consumption of liver cells. HELMUTH REINWEIN AND WALTER SINGER. Med. Klin. Würzburg and Physiol. Inst., Zürich. *Biochem. Z.* 197, 52-9(1928).—Pure thyroxine like the thyroid ext. causes an increase in the O₂ consumption of surviving liver cells. The addn. of adrenaline, when its concn. exceeds 10⁻⁴, causes an inhibition of O₂ consumption. No increase in the O₂ consumption resulted from insulin, which in higher concns. injures the tissue respiration. S. MORGULIS

The influence of different quinine groups on the enzymic functions of the organism. IX. Effect of quinine on the dynamics of hydrolysis of carbohydrate and fat. I. A. SMORODINTZEV. Tropeninstitut des Volkskommissariats für Gesundheitswesen, Moscow. *Biochem. Z.* 197, 160-9(1928).—The hydrolysis of carbohydrate is generally increased in the presence of quinine. In most instances it causes an increased hydrolysis of fat though that of maltose and sucrose is unaffected. The tributyrase of the digestive fluid and serum is sensitive to quinine but the organtributyrase is resistant. In other words, quinine inhibits the fat assimilation in the intestine but has no effect on the fat metabolism in the organism. However, the inhibition of digestion of fat in the intestine is found at p_H 8.0 or above, whereas on the acid side the process is accelerated. In the upper intestine fat assimilation must therefore be improved by the quinine. Cf. C. A. 22, 4546. S. MORGULIS

Effect of carbon monoxide on the metabolism of white blood cells. AKIJI FUJITA. Kaiser Wilhelm-Inst. Biologie, Berlin-Dahlem. *Biochem. Z.* 197, 189-92(1928).—The glucolysis of white blood cells in O₂ is small but in CO under similar conditions in the dark it is large (70% of the anerobic value). Under the influence of illumination this glucolysis drops from 70 to 10%, but rises once more when returned to the dark. S. MORGULIS

Animal poisons in chemistry. ANGELO CONTARDI AND TIA LATZER. Serotherapeutisches Institute, Mailand. *Biochem. Z.* 197, 222-36(1928).—The wasp poison, unlike bee, snake or scorpion poisons, has the addnl. property of sapon. salts of glycerophosphoric acid at low temps. (50°). These poisons have no effect on ordinary fats or on plant phosphatides. S. MORGULIS

Effect of glycocoll on the blood sugar. G. PAASCH. Med. Klinik, Würzburg. *Biochem. Z.* 197, 460-6(1928).—Glycocoll has no definite hyperglucemic effect in dogs or rabbits. S. MORGULIS

Experimental studies on the influence of narcotics on the blood-sugar concentration. K. STEINMETZER AND F. SWOBODA. Physiol. Inst. Tierärztliche Hochschule, Wien. *Biochem. Z.* 198, 259-67(1928).—Various narcotics (ether, morphine, chloral hydrate, hedonal) cause hyperglucemia which generally lasts on the av. 6 hrs. and always continues longer than the narcosis. The blood sugar increased 30-50% over the normal blood-sugar values. Even non-effective doses of hedonal or chloral hydrate produced hyperglucemia which lasted a long time. This hyperglucemic reaction is regarded as due to the removal of inhibition from the sugar center in the brain. S. MORGULIS

Effect of naturally occurring iron compounds on the metabolism. A contribution to the problem of active iron. M. KOCHMANN AND H. SEEL. Pharmacol. Inst., Fried-

rich-Univ., Halle-Wittenberg. *Biochem. Z.* 199, 362-78(1928).—The administration of water contg. Fe bicarbonate giving the benzidine reaction to young rats increases their growth greatly. To a lesser degree the body wt. is increased by adding similar quantities of FeSO_4 to the food. The rats receiving the mineral water show an increased O_2 consumption, also per g. of body wt., and show the same higher metabolic rate as young actively growing rats. FeSO_4 has a similar though much weaker effect.

S. MORGULIS

Thyroid gland and mineral metabolism. Influence of disodium phosphate and of calcium salts on the effect of thyroid substances. I. ABELIN. *Physiol. Inst., Univ. Bern. Biochem. Z.* 199, 72-106(1928).—The effect of thyroid gland substances on the basal metabolism is greatly increased by inorg. salts. Administration of Na_2HPO_4 increases, and of Ca salts diminishes the metabolic influence. The Ca salts produce a particularly striking inhibitory effect on the overexcitability symptoms. Neither Na_2HPO_4 nor Ca salts have any direct effect upon basal metabolism. The glycogen-forming capacity of the liver, in spite of the feeding of thyroid, can be retained unimpaired in many instances through the administration of CaCO_3 . The CaCl_2 salt is not suitable to use because of its hydrolysis. The Ca theory of goiter receives certain support from this observation of the actual antagonism between the thyroid function and excess of Ca. Continued Ca-rich food, like a predominantly milk diet, may at last create conditions which are unfavorable for the activity of the thyroid hormone. The action of adrenaline on the basal metabolism is not noticeably affected by repeated administration of Ca salts.

S. MORGULIS

The effect of hypertonic glucose solutions on the excretion of water and chlorides through the kidney. I. I. M. GOLDBERG, S. M. GAMEROV AND M. L. PINCHASSIK. *Lab. pathol. Physiol., Institute of Medicine, Leningrad. Biochem. Z.* 199, 107-14(1928).—Intravenous injection of hypertonic glucose solns. affects the H_2O distribution in that the muscle water content diminishes and that of blood and liver increases. The Cl content of blood, muscle and liver remains unchanged. The urinary excretion generally diminishes but sometimes it is unaffected, the Cl varying with the total urine quantity. II. Experiments on thyroidectomized animals. I. M. GOLDBERG, M. L. PINCHASSIK AND S. U. GAMEROV. *Ibid* 115-20.—The influence of injected hypertonic glucose solns. on the water distribution in the organism is not nearly as prominent in thyroidectomized animals as was found to be the case in normal animals. On the other hand, the reduction in the quantity of urine excreted is much greater in the operated animals.

S. MORGULIS

Influence of arsenic on the carbon and oxygen coefficient of the urine. L. KOROWSKY. *Pathol. Inst. Univ., Berlin. Biochem. Z.* 199, 366-76(1928).—The effect on metabolism produced by As depends on whether it is given perorally or subcutaneously and the metabolic changes disappear quickly if the As treatment lasted only a few days. The same effect was produced with inorg. and org. As compds; generally treatment with As causes a rise in both the C and O coeffs. of the urine, and the same is true for therapeutic or toxic doses, and this indicates a lowering of the oxidation. Exceptionally there is a lowering of the coeff. following a toxic dose of As. The quotient is unchanged under the influence of therapeutic dose. The variations in both C/N and O/N coeffs. under the influence of As are generally parallel.

S. MORGULIS

The blood-sugar level in nicotine poisoning. A. I. BURSTEIN AND I. D. GOLDENBERG. *All-Ukraine Inst. for Hygiene and Pathol. of Labor, Odessa. Biochem. Z.* 200, 115-25(1928).—Poisoning with small, medium or large doses of nicotine is accompanied by a rise in the blood-sugar concn. This occurs within 15-30 min. after the nicotine injection into the blood followed by a fall in concn. so that there is a return to the normal level after 3-3½ hrs. In chronic nicotine poisoning no lasting effect on the blood-sugar level is found. The rise in sugar following an injection of nicotine is ascribed to an adrenalinemia. There is no depression of glycolysis in nicotine poisoning.

S. MORGULIS

The origin of the alkaline reaction in the intestinal juice. KENSA OYAMA. *Med.-chem. Inst. Univ. Kanazawa. J. Biochem. (Japan)* 9, 1-16(1928).—Aq. solns. of NaCl or neutral salts or sucrose, when introduced into the intestinal canal, cause an increase in alky. If these solns. are introduced into an excised segment of the intestine and after a certain time the remaining fluid is investigated, it is found that the anions have been better adsorbed than the cations, especially the Na^+ . When aq. isotonic solns. of glucose, or such neutral salts like KCl, NH_4Cl or NaI, are injected into the intestine, NaCl passes from the blood into the canal.

S. MORGULIS

Pentosuria in experimental stasis icterus and following subcutaneous injection of bile acids in rabbits. TODI KOBAYASHI. *Physiol.-chemisches Inst., Okayama.*

J. Biochem. 9, 251-60(1928).—Bile acids provoke pentosuria, the pentose apparently arising from the body nucleins. S. MORGULIS

Effect of ergotamine on experimental hyperglucemia. GENICHIRO ODA. Med. Klinik, Kaiserliche Univ., Tokyo. *J. Biochem. (Japan)* 9, 285-97(1928).—Hyperglucemia due to diuretin, caffeine, pilocarpine, quinine, antipyrine, pyramidone, picrotoxin or salt can be more or less definitely reduced by subcutaneous injection of 0.5 mg. ergotamine. Frequently, this will even result in a hypoglucemia. This is thought to indicate that the above-named hyperglucemias are caused by sympathetic excitation. S. MORGULIS

Effect of hormones, parasympathetic drugs, alkaloids and various salts on the hypoglucemic action of bile acids. AIJIRO TAKU. Physiol.-chem. Inst., Okayama. *J. Biochem. (Japan)* 9, 299-319(1928).—Insulin promotes and adrenaline inhibits the hypoglucemic action of cholic acid. Pituirrin is apparently without any effect. The parasympathetic poisons, atropine and pilocarpine, inhibit the hypoglucemic action, as do also the alkaloids morphine, cocaine and caffeine. Morphine has a stronger antagonistic action to the bile acids than either cocaine or caffeine. CaCl₂ and MgCl₂ inhibit the hypoglucemic effect of the bile acids while KCl increased this. S. M.

Parenteral administration of sucrose and invertase. TOSIO ODA. Med.-chem. Inst., Universität Chiba. *J. Biochem. (Japan)* 9, 383-405(1928).—Intravenously injected sucrose disappears in rabbits in about 5.5 hrs. In rabbits receiving several injections of sucrose at 7-day intervals, one week after the last injection it was found that the liver, spleen, kidney, muscle and blood contained neither invertase nor lactase. Similar expts. with raffinose injection led to the same conclusion as to the absence of raffinase or lactase. Injections of yeast sucrase preps. intravenously cause a rise of the invertase action of the blood for only a short time (1-1½ hrs.) even when the enzyme is injected repeatedly into the same rabbit. Most of the invertase is found in the liver, some in the spleen and occasionally in the bone marrow, but in none of the other organs. An injection of sucrose 10 min. to 6 hrs. after an injection of invertase gave invariably neg. results. When the two are injected as nearly simultaneously as possible there is evidence than an inversion of the sucrose does take place *in vivo*. S. M.

The pharmacology of mistletoe (*Viscum album*). J. NOLLE. Chímico-farmacéutical Inst., Moscow. *Zhurnal expil. Biol. Med.* 9, 266-75(1928).—Exts. of mistletoe produce depression of the nervous system of cold-blooded animals without a preliminary excitatory stage. It causes gradual slowing of their heart beat, probably through weakening its nervous mechanism, but in warm-blooded animals the slowing of the heart is not marked. In all doses, the mistletoe ext. lowers blood pressure because of its injurious action on the vasomotor centers. On the isolated heart the ext. acts by increasing the amplitude of the beat but slowing its rhythm somewhat. On the vessels of the isolated ear, liver or kidney it acts as a dilator. In both cold- and warm-blooded animals the ext. slows up the respiration without a preliminary excitatory phase. It is pointed out that the therapeutic effect of this ext. in hypertony should be investigated. S. M.

Effect of some poisons on the corpora cavernosa and on the vessels of the dog's penis. A. NIKULIN. Pharmacol. Lab., Univ. Saratow. *Zhurnal expil. Biol. Med.* 9, 335-51(1928).—Both the blood vessels and the corpora cavernosa of the penis are very sensitive to various poisons. Adrenaline in diln. of 1:500,000-1:25,000,000 contracts the vessels and stimulates the plain muscles of the corpora cavernosa. Atropine, pilocarpine, arecoline and physostigmine have no marked effect on the vessels. Nicotine, BaCl₂, cocaine, digitalis and strophanthin constrict the vessels, while caffeine, quinine, chloral hydrate and NaNO₂ cause dilatation. "Tenosin-Bayer" in a diln. of several billions still produces vascular dilatation. Conclusion: the vascular innervation of the penis is predominantly if not exclusively of the sympathetic nervous system. S. M.

Studies on the pharmacology of *d*- and *l*-camphor. Comparative action on frogs of Japanese camphor and its *l*-isomer. K. A. SHMELEV AND N. V. GOLYAKHOVSKII. Pharmacol. Lab., Saratow State Univ. *Zhurnal expil. Biol. Med.* 9, 384-92(1928).—*l*-Camphor from *Artemisia maritima astrachanica*, which is the optical antipode of the ordinary camphor, causes typical paralysis of the central nervous system of *Rana esculenta* in no sense different from that produced by the Japanese *d*-camphor. The 2 forms, the *l*- and *d*-camphor, do not vary in the degree of their activity, both equally producing fibrillary contractions in the skeletal musculature in the stage of deep poisoning. Both equally lower the indirect elec. irritability of muscles without, however, giving the picture of a typical curare effect. Neither of these isomers affects noticeably the direct irritability of the striated muscles when injected subcutaneously even in lethal doses. S. MORGULIS

Effect of insulin and adrenaline on the distribution of glucose in the blood. S. I.

VINOKUROV. Ukraina Biochem. Inst., Charkow. *Zhurnal ekspt. Biol. Med.* 9, 394-407(1928).—The red cells of pigeons contain glucose but in smaller concn. than the plasma, but the cells contain by far the largest portion of the substance responsible for the residual reduction of the blood. Only 50% of the reduction obtained by the pigeon cells is due to glucose. In hyperglucemia, this proportion of residual reduction increases, and a proper correction for this must be made where hyperglucemia is studied. Under the influence of large insulin doses the difference between the cells and the plasma in the matter of the uneven distribution of glucose and residual reduction is wiped out: in plasma the glucose decreases and the residual reduction in the red cells increases. Under the influence of adrenaline the cells lose the glucose so that the difference in glucose concn. between cells and plasma becomes very great. There are also instances of hyperglucemia not caused by adrenaline accompanied by a rise in the cell glucose content. S. MORGULIS

Effect of poisoning with illuminating gas on the placental barrier. E. LOKSHIN AND R. R. FLAK. Metschnikoff Inst., Moscow. *Zhurnal ekspt. Biol. Med.* 9, 455-62(1928).—Poisoning with illuminating gas increases the permeability of the placenta to I or Bi, but not to $\text{Na}_4\text{Fe}(\text{CN})_6$, trypan blue or Congo red in rabbits. In mice there were no changes at all. S. MORGULIS

Charcoal as an antidote in poisoning with poisons of various pharmacological groups. E. A. LEIBENSON. State Med. Inst., Odessa. *Zhurnal ekspt. Biol. Med.* 10, 58-63 (1928).—Activated charcoal from linden is a valuable antidote for poisoning. The charcoal must be used very quickly while the poison is still in the stomach. Even with poisons of the morphine group which are administered subcutaneously charcoal is effective because the poison is excreted through the gastrointestinal tract. The charcoal antidote must be given in accordance with the following rules: the stomach is first washed out with a 15% charcoal mixt., whereupon 15 g. charcoal in 100 g. of 1% NaHCO_3 is introduced. The last is necessary because the adsorption of the coal begins at pH 3.9. After $1\frac{1}{2}$ hrs. it is necessary to administer 100-150 cc. 35% Na_2SO_4 which aids the gastrointestinal secretion of the last traces of poison and also induces the evacuation of the adsorbed poison. Even in poisoning with substances which are not adsorbed by charcoal, the latter by spreading in a thin layer over the mucous membrane effectively prevents further absorption of poison as well as the corrosion of the membrane. The neutralization of acids or alkalies by proper antidotes is more easily accomplished following preliminary treatment with charcoal. S. MORGULIS

Materials for the study of the pharmacology of *d*- and *l*-camphor. II. Effect of the *d*- and *l*-isomers of camphor and their colloidal preparations on the normal frog heart and on the heart poisoned with chloral hydrate. K. A. SHMELEV AND N. V. GOLYAKHOVSKI. Pharmacol. Lab. State Univ., Saratow. *Zhurnal ekspt. Biol. Med.* 10, 83-95(1928).—Both isomers produce the same effect on the frog heart whether in Ringer's sol. (diln. 1:5000-30000) or as an external application in a colloidal soln. Likewise, both isomers equally restore the beat to the heart which has stopped under the influence of chloral hydrate. S. MORGULIS

The influence of caseosan on the animal organism. C. A. LEVENE. Pharmacol. Lab. State Med. Inst., Odessa. *Zhurnal ekspt. Biol. Med.* 10, 102-8(1928).—Subcutaneous injections of 1 cc. caseosan once or twice a week for a period of 2-4 weeks produces no anaphylactic phenomena. The injection is accompanied by a rise of rectal temp. of $0.4-0.5^\circ$ the first 2 hrs. Given intravenously to dogs in doses of 1.25-2 cc. per kg. it has no great effect on the blood pressure nor on the frequency of the heart beat. In rabbits subcutaneous injections of caseosan causes only a slight slowing of the respiration. In 75% of the rabbits caseosan does not alter the sensitivity of the respiratory center to morphine but increases the rabbits sensitivity to the general action of morphine. Caseosan diminishes very considerably the effect of alc. on the rabbit. S. MORGULIS

Further experimental data on *Bulbus scillae maritimae* and its glucoside scillaren. B. N. DUBINSKII. Pharmacol. Inst. Med. Inst., Charkow. *Zhurnal ekspt. Biol. Med.* 10, 122-32(1928).—*Bulbus scillae maritimae* and its glucoside scillaren slows the rhythm and increases the systolic cardiac power, increases the amplitude of the pulse wave and raises the blood pressure. This action is regarded as its therapeutic effect and is opposed to its second action, the toxic due to considerable resorption, which manifests itself in an acceleration of the heart rhythm, shortening of the diastole, increased cardiac tonus leading even to a state of contracture, the blood pressure remaining for a long time high but finally falling even below the normal level. The secondary, toxic acceleration of the heart is due to an irritation of the neuro-muscular mechanism of the heart. Expts. on isolated organs show that small doses of scillaren dilate the vessels and large

doses constrict them, so that the raising of the blood pressure is due to the increased heart action and to a certain extent also to the peripheral effect: In the first 3-4 mins. of the therapeutic phase of its action the blood pressure rise is purely a haemodynamic action; the peripheral effect does not occur until later. In the toxic phase the increased heart rhythm compensates for the diminished systolic strength and with the increased vasoconstriction present, the blood pressure is maintained high. The kidney vessels are more sensitive to the vasodilating effect while the ear vessels are more sensitive to the vasoconstricting effect of scillaren.

S. MORGULIS

Action of adrenaline and of dihydroxybenzene on the heart and vessels. A. SANGAJLO. Pharmacol. Lab. II Univ., Moscow. *Zhurnal expil. Biol. Med.* 10, 212-8 (1928).—Adrenaline as well as dihydroxybenzene (pyrocatechol, hydroquinone, resorcinol) acts upon the heart not only at the time of penetration but also at the subsequent stage of leaving the tissue. The absence of side chains in the dihydroxybenzene compds is thought to be responsible for their weaker action as compared to adrenaline. S. M.

The anti-coagulant action of the venom of the rattlesnake, *Crotalus adamanteus*. ALBERT P. MATHEWS. Univ. Cincinnati. *Arch. sci. biol.* (Italy) 12, 145-52 (1928); cf. Houssay and Sordelli, *C. A.* 13, 2377; 14, 947, 2030; 15, 899.—The anti-coagulant action of rattlesnake venom is in part, but not wholly, due to its destruction of cephalin. Another very important part of the action is due to the intense, rapid and sp. destruction of fibrinogen. The venom does not appear to destroy tissue fibrinogen, one of the 2 important constituents of thrombokinase. It does not appear to destroy cephalin when the venom is in union with protein. Its destruction of blood fibrinogen has many points of resemblance to the similar destruction brought about by illuminated hematoporphyrin.

L. W. RIGGS

Reciprocal influence of folliculin and insulin on the glucemia of ovariectomized dogs. F. RATHERY, R. KOURILSKY AND Mlle Y. LAURENT. *Compt. rend.* 187, 467-70 (1928).—In 3 ovariectomized dogs folliculin exercised upon insulin an effect opposite to that which occurs in the normal animal, in the sense that it exaggerated the hypoglucemic effect of the pancreatic hormone. In 2 other dogs folliculin had the same effect toward the action of insulin as in the normal dog, in that it restrained the action of insulin.

L. W. RIGGS

Hemodynamic action of epinephrine. CARL A. DRAGSTEDT. Northwestern Univ. *J. Am. Med. Assocn.* 91, 1035-6 (1928).—The min. effective dose of epinephrine in the unanesthetized dog is less than from 0.2 to 0.4 cc. of a 1 to 1 million soln. of epinephrine per kg. per min. This produces pressor effects. The vascular (pressor) response to epinephrine is more sensitive than the intestinal inhibition both in the unanesthetized dog and in man. Compatible suprarenal vein blood collected from one dog and re-injected into a second unanesthetized dog at the rate at which it was collected has a slight pressor effect absent in the systemic blood. From these expts. there is no reason to suppose that the suprarenals are not normally and continually secreting epinephrine in amts. sufficient to modify the vascular bed, and there is reason to believe that an augmentation of secretion will have hemodynamic effects.

L. W. RIGGS

Toleration of the diuretic action of caffeine. GYOKUJO KIHARA. *Proc. Imp. Acad. Tokyo* 4, 418-20 (1928).—Rabbits acquire a moderate degree of tolerance toward caffeine following upon repeated administration of gradually increasing doses of the drug. It requires from 4 to 6 months for the full development of the toleration. The development of a decreased susceptibility to the diuretic action of caffeine is shown at first in the cessation of the extra-renal response (hydremia), and next in that of renal response. But the renal vaso-dilation to be seen immediately after the injection of caffeine appears in a caffeine-tolerant as well as in a control animal. An animal tolerant toward caffeine, theobromine and theophylline manifests a decreased susceptibility to each of these. In caffeine-tolerant rabbits, as in a control animal, no increase in the O consumption of the kidney was produced by caffeine injection.

L. W. RIGGS

Edema formation. III. Influence of potassium and calcium on edema production during disturbed thyroid functioning. CHROMATSU SATO. *Tôhoku J. Expil. Med.* 11, 232-45 (1928); cf. *C. A.* 22, 4171.—In the perfusion of thigh preps. of healthy animals with Ringer soln., an increased quantity of KCl or CaCl₂ in the Ringer soln. at first arrests but later promotes edema formation. These 2 actions adjust themselves gradually according to the concn. of the salts. Perfusion of thigh preps. from animals with disturbed thyroid functioning with Ringer soln. contg. an increased quantity of KCl or CaCl₂ caused, in hyperthyroidism, a reduction of the edema, and in athyroidism an increase of the edema formation. The action of K and Ca salts thus introduced varies with their concn. K salts have a stronger tendency to reduce the edema in hyperthyroidism and Ca salts a stronger tendency to increase the edema of athyroidism.

Action of novasurol and theocin (theophylline) on edema formation by perfusion experiments with normal and experimentally abnormal animals. *Ibid* 246-64.—Novasurol added to Ringer soln. in thigh prep. perfusion expts. accelerates the formation of tissue edema in animals poisoned with cantharidin or $\text{UO}_2(\text{NO}_3)_2$. Theocin increases edema formation in perfusion expts. with normal animals, but in animals poisoned with cantharidin or $\text{UO}_2(\text{NO}_3)_2$ it diminished the edema formation. L. W. RIGGS

Pharmacological action of soaps. IV. Toxic and anticoagulating effects of oleic acid. ANGELO RABBENO. • Univ. Pavia. *Arch. expil. Path. Pharmacol.* 134, 17-28(1928).—Stable, homogenized emulsions of oleic acid in water were tested for toxicity by intravenous injections in rabbits and for coagulation-inhibiting properties both *in vivo* and *in vitro*. Compared with Na oleinate and Ca oleinate, oleic acid is half as toxic as the Na compd., and is more toxic than the Ca compd., the minimal lethal doses being oleic acid 0.000920, Na oleinate 0.000455, Ca oleinate 0.001280. Injected intravenously oleic acid interferes with coagulation, while *in vitro* if added to a concn. of 0.016 g. per l. coagulation is prevented. In this respect, oleic acid retards coagulation to about the same degree as does Na oleinate and somewhat more effectively than does Ca oleinate. G. H. S.

Thyroid function and the effect of adrenaline upon blood pressure. WILLY KÖNIG. Westf. Wilhelms-Univ. Münster i. W. *Arch. expil. Path. Pharmacol.* 134, 36-43(1928).—In neither normal rabbits nor those deprived of thyroid is the action of adrenaline augmented by a simultaneous administration of thyroxine. Prolonged preliminary treatment of normal animals with thyroxine does not definitely increase adrenaline sensitivity. When deprived of thyroid, animals respond less vigorously to adrenaline, but a preliminary treatment with thyroxine enables them to respond in an almost normal fashion. G. H. S.

Experiments upon the amnion of the hen and goose. Pharmacological study with nerve-free smooth muscle. MAX BAUR. Univ. Kiel. *Arch. expil. Path. Pharmacol.* 134, 49-65(1928).—Automatic myogenic motility was increased, or in inactive preps. instituted, by Ba, gynergen, physostigmine, acetylcholine, choline, strophanthin, muscarine, tenosine, pituitrin and hypophysin. Papaverine, pantopon, tincture of opium, adrenaline, cocaine, morphine, dihydromorphinone and cardiazole exerted a paralyzing action. G. H. S.

Effect of extracts of the posterior lobe of the hypophysis on choleresis and cholekinesis. Influence of narcotics. D. ADLERSBERG AND J. M. NOOTHOVEN VAN GOOR. Univ. Wien. *Arch. expil. Path. Pharmacol.* 134, 88-104(1928).—Pituitrin does not modify cholekinesis in rabbits although it does exert an inhibitory action as regards choleresis, and this latter effect is not influenced by section of the vagus, or by the simultaneous administration of urethan. Chloretone, and to a lesser extent luminal, weaken or completely prevent the action of pituitrin. Clinical studies in man show that under normal conditions pituitrin regularly modifies cholekinesis but no conclusive proof of an inhibition of choleresis can be obtained. The cholekinetic action is not removed by the administration of paraldehyde, while it is diminished or abolished by chloretone and luminal. G. H. S.

Do fractional doses of poisons exhibit a greater effect than does a single dose of the same amount? L. LENDLE. Univ. Leipzig. *Arch. expil. Path. Pharmacol.* 134, 113-28(1928).—Fractional injections of some narcotics—avertin, urethan, amylene hydrate and isoamyl alc.—cause no increased narcosis in rats as compared with a single injection of the same total amt. Similarly, amylene hydrate given rabbits intravenously in fractional doses is not more effective than is a single dose. When given subcutaneously, however, amylene hydrate and urethan by divided dosage show some increased effect; this is due solely to the distribution of the agent in several injection areas with a resultant accelerated absorption. G. H. S.

Studies on alcohol. VII. Effect of alcohol on gastric digestion. G. FRANZEN. Univ. Jena. *Arch. expil. Path. Pharmacol.* 134, 129-41(1928).—As has been observed under exptl. conditions, certain concns. of alc. stimulate peptic digestion under natural conditions. When the concn. in the stomach goes above 5-7% gastric activity is retarded, but lower concns. are either without effect or are stimulating. G. H. S.

Mobilization of mercury by halogen salts from deposits in which it is difficultly soluble. FAUSTINO GARCIA. Univ. München. *Arch. expil. Path. Pharmacol.* 134, 142-8(1928).—When compds. of Hg which are insol. in water, such as calomel and the oxide, biniodid and salicylate of Hg, are deposited in the subcutaneous tissues no symptoms of intoxication become manifest unless the quantity injected exceeds a certain value. If, however, such a Hg injection is given in conjunction with the administration of

halogen salts (iodide, chloride, bromide) a typical fatal intoxication ensues. In Hg mobilizing effect KI is more potent than NaCl, and KBr is least active. G. H. S.

Quantitative pharmacological differentiation of solanaceae alkaloids. FAUSTINO GARCIA. Univ. München. *Arch. expil. Path. Pharmacol.* 134, 149-54(1928).—Sublethal doses of atropine, hyoscyamine and scopolamine do not cause narcosis in mice, but if mice injected with such doses of these substances are subsequently exposed to a non-narcotizing amt. of ether (0.25 cc. in 5 l. of air) a deep narcosis will sooner or later develop. The interval elapsing between injection of alkaloid and exposure to ether is of considerable importance, a max. effect being observed when the interval was between 30 and 60 min. With all 3 alkaloids the time required for the narcotizing effect to become manifest diminishes as the amt. of alkaloid injected is increased. Of the 3 alkaloids atropine was the most active; scopolamine required the largest doses. Upon the basis of these observations the activity of alkaloid preps. can be detd. G. H. S.

Effect of the continued administration of insulin upon the adrenal of rabbits. HEDWIG LANGECKER. Univ. Prag. *Arch. expil. Path. Pharmacol.* 134, 155-67(1928).—From the standpoint of both abs. and relative wt. the adrenals of rabbits which have been continuously treated with insulin are heavier than those of normal rabbits. While the hypertrophy of the organ involves the cortex primarily, the medullary portion is also increased somewhat since the content in adrenaline is greater than normal. Comparative values as to the adrenaline content of hypertrophied and normal organs are valid when a period of at least 7 days has elapsed after the last injection. Immediately after the insulin injection the adrenaline is largely without pressor effect. Although upon the basis of biological detn. the adrenaline is diminished by the injections, colorimetrically the adrenaline content is unchanged. G. H. S.

Toxicology of some chlorine derivatives of methane and ethane. G. A. MALOFF. Univ. Berlin. *Arch. expil. Path. Pharmacol.* 134, 168-72(1928).—The effects were detd. upon the basis of the fat content of the liver, which was increased by CHCl_3 and by tetrachloromethane. Dichloromethane, ethylene dichloride, ethylidene chloride and hexachloroethane were without effect. G. H. S.

Effect of adrenaline upon the formation of sugar. E. GEIGER AND EUGEN SCHMIDT. Univ. Pécs. *Arch. expil. Path. Pharmacol.* 134, 173-84(1928).—In the dog with phlorhizin diabetes the administration of adrenaline causes but once an increase in carbohydrate, and this is referable to a mobilization of muscle glycogen. The fat content of the liver is unchanged. G. H. S.

Constipating effect of charcoal. HELLMUT BAUER. Univ. München. *Arch. expil. Path. Pharmacol.* 134, 185-90(1928).—The administration of charcoal doubles the period required for material to pass through the intestinal canal of rats. Charcoal likewise inhibits the increased peristalsis induced by castor oil. The choline of the feces is markedly increased by the administration of charcoal, and if both charcoal and castor oil are given the increase in choline is still greater. G. H. S.

Effects of continued saponin administration. Significance of the distribution of cholesterol and the possibility of a reversal of metabolism in the mammalian body. II. HANS HANDOVSKY. Univ. Göttingen. *Arch. expil. Path. Pharmacol.* 134, 191-202(1928).—The continued intravenous administration of saponin offers a method of effecting changes in the distribution of cholesterol within the body. Cholesterol detns. of the skeletal muscle and liver of rabbits which had received 0.6 mg. per kg. of saponin every other day were supplemented by detns. of the carbohydrate and lactic acid values for the muscle, and in some instances of blood sugar. Since earlier studies had indicated that the nature of the effects were to some degree related to the sex of the animal, the results herein reported are considered upon that basis. During the first 9 days of treatment male animals show a marked increase in muscle carbohydrate and no change in the lactic acid or cholesterol of the muscle or in cholesterol of the serum. During this same period female animals show rather a tendency toward a hypoglycemia; muscle carbohydrate diminishes as does lactic acid and cholesterol. As the saponin administration is continued up to the 18th day the situation as regards metabolism changes in that both males and females show much the same picture. In both, the muscle carbohydrate is reduced and lactic acid is increased. The cholesterol of muscle is reduced in females more than in males, and the water content of the muscle is reduced. Study of the liver shows that the glycogen content is high as is the cholesterol. Carbohydrate consumption, O_2 utilization and CO_2 production are higher in the saponin animals than is normal. Apparently the increases in metabolism due to saponin are referable to an increased permeability of the cells. In animals treated for more than 18 days the respiration of liver cells approaches normal, but there is an excess of lactic acid production. These later changes in the liver occur in both sexes, but the changes which

develops in muscle at this time differ with sex. Subsequent changes, i. e., those occurring after the 23rd day, likewise differ according to sex. Apparently the differential effects based upon sex are referable to the action of saponin upon the adrenals and the germinal glands, particularly the testes. G. H. S.

Explanation of the stimulating effect of saponins upon resorption. LUDWIG PETSCHACHER AND PAUL FELDER. Univ. Innsbruck. *Arch. expul. Path. Pharmacol.* 134, 212-7(1928).—Saponin increases secretion and diastatic action. G. H. S.

Theory of the identity of action of calcium and adrenaline. O. EHRLMANN. Univ. Berlin. *Arch. expul. Path. Pharmacol.* 134, 247-51(1928).—Upon the isolated intestine prepn. of rabbits, rats and cats Ca is sometimes stimulating and sometimes exerts a paralyzing action, while adrenaline is always inhibitory. Upon infantile uteri of rats and cats Ca is always stimulating, adrenaline always inhibitory, while with isolated uterus of rabbits Ca at times causes paralysis, adrenaline at times exerts a stimulation. All of these facts contradict the theory that assumes an identity of action for Ca and adrenaline. G. H. S.

Effect of section of the vagus and of morphine upon the respiratory gas exchange. HANS MELTZER AND M. STREUBER. Landwirtsch. Hochschule, Berlin. *Arch. expul. Path. Pharm.* 134, 259-73(1928).—Respiration in dogs is modified by section of the vagus, the effects being dependent upon whether both vagi or but one vagus is cut. With unilateral vagotomy the sole effect is a considerable reduction in respiratory rate, a change which is but transitory. When both vagi are sectioned respiration is permanently retarded. Death occurring in animals so treated is not due to a disturbance in pulmonary gas exchange. Morphine stimulates respiration but diminishes the abs. respiratory vol. and the O_2 utilization while the alveolar CO_2 tension is greatly increased. G. H. S.

Fate of inorganic iron in the body after the administration of simple inorganic ferro- and ferri-compounds. E. STARKENSTEIN AND H. WEDEN. Univ. Prag. *Arch. expul. Path. Pharm.* 134, 300-16(1928).—The living body behaves as regards simple inorg. Fe compds. just as do surviving organs. Pharmacol. active ferro salts, as the chloride, are oxidized to the ferri form and as such in soln. remain in the body fluids and plasma for a long time. Inorg. ferri compds. can be introduced into the body only in the colloidal form, such as Fe albuminate. They are reduced, but the compds. which form differ from the ferro chloride, since they are insol. in water and undergo little, if any, oxidation. Further, these compds. lack all pharmacol. action. Inactive ferri compds., such as sugar of Fe, are quickly removed from the blood by the spleen and liver. G. H. S.

Hormonal effect of glucose for insulin production. E. GEIGER. Univ. Pécs. *Arch. expul. Path. Pharm.* 134, 317-23(1928).—The effect of sugar upon insulin production is not a sp. action, as suggested by Grafe and Meythaler. Apparently the effect is due simply to a stimulation assocd. with hypertonicity. G. H. S.

Theory of insulin action. I. HANS HANDOVSKY. Univ. Göttingen. *Arch. expul. Path. Pharm.* 134, 324-38(1928).—Insulin administration caused a reduction in the carbohydrate and glycogen of muscle, a change which takes place very quickly. II. *Ibid* 339-46.—Apparently the prompt reduction in the sugar of the blood following the administration of insulin is assocd. with the presence of S in the substance. S likewise sensitizes the muscle to the action of insulin. G. H. S.

Behavior of plexus-containing and plexus-free preparations of intestinal muscle. L. W. VAN ESVELD. Univ. Utrecht. *Arch. expul. Path. Pharm.* 134, 347-86(1928).—Prepns., both with or without plexus, react to elec. stimulation with a refractory period, but this is less marked with plexus-free prepns. In any case the refractory state is but relative, for with either type of prepn. a sufficiently strong stimulus is effective. Both plexus-free and plexus-contg. prepns. react to atropine, pilocarpine, physostigmine, choline, acetylcholine, muscarine, histamine, adrenaline, nicotine, strophanthin and $BaCl_2$. To these agents, in suitable concns., some plexus-free prepns. react; others do not. This behavior is not connected with the presence or absence of scattered ganglion cells. Differences in action due to the presence or absence of plexus can, however, be detected, since of the two, plexus-free prepns. are from 100 to 1000 times less sensitive to pilocarpine, physostigmine, choline, acetylcholine, muscarine and histamine, from 10 to 50 times less susceptible to adrenaline and nicotine. To strophanthin both prepns. are almost equally sensitive; and to $BaCl_2$ they react in exactly the same manner. The presence of Auerbach's plexus is responsible for the increased activity of the plexus-contg. prepn. Poisons tend to favor rhythmic motion of the prepns. with plexus, but not of those which are plexus-free. For the latter atropine is never stimulating. G. H. S.

Etiology of oroxy fever. XIII. Chemotherapy in experimental Bartonella bacilliformis infection. HIRAYO NOGUCHI. Rockefeller Inst. Medical Research, New York. *J. Exptl. Med.* 48, 619-25(1928).—The therapeutic effect of several antiparasitic chemicals (Bi albuminate, tatar emetic, neoarsphenamine, tryparsamide, HgCl_2 , novasurol, merurochrome, neutroflavine, optochin, Na tetrocholate, PhOH , HCHO , and lugol's soln.) on exptl. *Verruca peruviana* is described. The drugs were administered by intravenous injection according as the nodules were already developed to an approx. max. or were still in the active period of growth. The effect of the drugs was different under the 2 circumstances of their administration. When they were given after maturity of the nodules they hastened the regressive process but when given during active growth of the lesions no action whatever was detected. *Bartonella bacilliformis* in culture is acted upon injuriously by a no. of the chemicals employed in the therapeutic tests, the most active being HCHO and neutraflavine. C. J. WEST

Effect of sodium chloride on the chemical changes in the blood of the dog after obstruction of the cardiac end of the stomach. RUSSELL L. HADEN AND THOMAS G. ORR. Univ. of Kansas. *J. Exptl. Med.* 48, 627-38(1928).—The effect of different treatments on the toxemia of cardiac obstruction is reported. The av. duration of life of untreated dogs is 3 days; 3 dogs treated with 1% NaCl soln. subcutaneously lived 32, 36 and 45 days, resp., without developing a toxemia; 2% glucose similarly given does not alter the course of the toxemia. Concd. salt soln. in small quantities given directly into the jejunum prevents the marked rise in non-protein N but does not materially prolong life. Release of the obstruction does not change the course of the toxemia in untreated animals. The subcutaneous injection of 1% NaCl soln. after release of the obstruction causes a rapid return of the blood to normal and allows the animal to recover. A similar amt. of fluid given as 2% glucose does not alter the course of the toxemia after release of the obstruction. C. J. WEST

Blood chlorides in proteose intoxication. RUSSELL L. HADEN AND THOMAS G. ORR. Univ. Kansas. *J. Exptl. Med.* 48, 639-45(1928).—Dogs injected with proteose recovered from the intestinal contents of animals with obstruction at different levels show no significant changes in the blood chlorides even with a fatal intoxication. After the intravenous injection of lethal and sublethal doses of Witte's peptone there is little change in the chlorides. Autolyzing liver in the abdominal cavity produces no change in the blood chlorides even with a very great increase in the urea and non-protein N. Proteose intoxication is probably not a factor in the characteristic fall in chlorides seen after intestinal and pyloric obstruction. C. J. WEST

The value of phosphorus and calcium in asthma, hay fever and allied diseases. ALEXANDER STERLING. *J. Lab. Clin. Med.* 13, 997-1005(1928).—Ca and P were of great benefit in the treatment of allergic diseases. This mineral deficiency in asthmatics, hay fever, and allied diseases, whether sensitivity can be proved or not, may be the missing link which makes the allergic differ from the normal. The addn. of Ca, P, and other minerals, e. g., Fe, Na and K salts, is possibly responsible for the favorable results in this series of cases. ETHEL W. WICKWIRE

A synthetic substitute for ephedrine. The chemistry, pharmacology and clinical application of phenylethanolamine sulfate (MILLER, PINESS) 17. The minimum lethal dose in pharmacy (SIMON) 17. Organic Bi derivatives (FABRYKANT) 10. Chaulmoogric oils. The oil of Gorli (ANDRÉ, JOUATTE) 10.

I—ZOOLOGY

R. A. GORTNER

Erythrocytaphagic capacity of the hepatic peritoneum in the splenectomized horned toad, *Phrynosoma solare*. H. E. JORDAN AND C. C. SPEIDEL. Univ. of Virginia. *Proc. Soc. Exptl. Biol. Med.* 25, 491-4(1928).—Examn. of the tissues of a splenectomized horned toad, 74 days after operation, revealed no splenic regeneration or compensatory myeloid metaplasia in any of the tissues examd. A striking change in the liver capsule had occurred, both serosal cells and subserous fibroblasts assuming intense phagocytic properties. The method by which the fragmenting erythrocytes are handled by the cells of the hepatic peritoneum is described. C. V. B.

The energy metabolism of *Paramecium caudatum*. A study of the function of the contractile vacuoles. WILHELM LUDWIG. Leipzig Univ. *Arch. Protistenk.* 62, 12-40(1928).—The metabolism of *Paramecium* is a function of the cell size. Figures for *Paramecium* of different sizes are given. FRANCES KRASNOW

Soil. A regulating factor of the medium for the cultivation of *Paramecium aurelia*. E. ANDREYEV. Pasteur Institute, Leningrad. *Arch. Protistenk.* 63, 94-104(1928).—

Soil, as well as other absorbants, adsorbs substances injurious to *Paramecium*. The soil that is added should be of a p_H comparable with the needs of the organism.

FRANCES KRASNOW

The occurrence of arsenic in fish. ERIK SADOLIN. *Dansk. Tids. Farm.* II, No. 7, 186-95(1928).—The method of Bang (*C. A.* 20, 1041) was used for quant. estn. of As. In codfish 2 analyses gave 0.4 and 0.8 mg. As per kg., muscular tissue; but 0.7 and 3.2 mg. As per kg. liver, in cod liver oil between 3.0 and 4.5 mg. As per kg. Olive oil and fat did not yield As. These results indicated that the As content of the liver is largely in the oil. Attempts were made to conc. the oil-sol. As compds. Oil was extd. with cold abs. alc. The ext. was shaken for 24 hrs. with a cold Na_2CO_3 soln. and the fatty acids obtained were partially crystd. by cooling. The liquid fatty acids were steam distd. under reduced pressure and the residue was extd. with alc. From 700 cc. cod-liver oil contg. 26 mg. As there was obtained 2 cc. contg. 2.0 mg. As. The oil-contg. muscular tissue from the cel was extd. with ether, whereby all As was removed from tissue, while in the oil 0.6 mg. As per kg. was found. Expts. with herring showed a content of 2.0 mg. As per kg. muscular tissue and 9.0 mg. As per kg. oil. When these results are compared with the expts. which have been carried out to det. the As compds. present in poisoned mammals (*Arch. intern. pharmacodynamic* 15, 399 (1905)), the conclusion must be that the compds. are different in the 2 cases. O. A. NELSON

Comparative pharmacological and physiological studies with muscle of marine animals. OTTO RIESSER AND ANNELIESE HANSEN. *Zoöl. Sta. Neapel. Arch. expil. Path. Pharm.* 134, 1-16(1928).—Analyses of the muscles of some invertebrate marine forms for phosphoric and lactic acids showed that the values characteristic for different species cover a wide range. Thus as regards phosphoric acid decapods gave values varying between 0.7795 and 0.912%, while octopods gave percentages between 0.456 and 0.5694. In the different species these values show far more constancy than did the lactic acid percentages. The latter ranged between 0.0205 and 0.1597% in decapods and between 0.0767 and 0.267% in octopods. Percentages for *Sipunculus* and muscles were: *Sipunculus*, phosphoric acid 0.425-0.4799, lactic 0.416; *Pinna*, phosphoric 0.171-0.3115, lactic 0.066-0.112; *Psammobia*, phosphoric 0.359; *Pecten*, phosphoric 0.4066, lactic 0.0491. Detns. of phosphoric acid in the foot-muscle of different species of snail showed that the amt. could be correlated with their phylogenetic arrangement; thus *Helix* gave 0.308%, *Trochus* 0.280%, *Natica* 0.256%, *Murex* 0.232%, *Helix* 0.193% and *Bulla* 0.144%. The lactic acid values showed no such regularity, nor did it prove to be more reliable in fish as differentiating different species of teleosts and elasmobranchs. Phosphoric acid, on the contrary, was more consistent. The muscles of various species of snail and mussel exhibited rather distinctive reactions to contracting agents, particularly to HCl. Teleost and elasmobranch muscles could be contrasted upon the basis of their behavior to acetylcholine and HCl. All fish muscles reacted in much the same fashion to veratrine and ammonia. G. H. S.

12—FOODS

F. C. BLANCK AND H. A. LEPPER

Report on (the determination of) coloring matters in foods: (quantitative separation of amaranth from tartrazine). C. F. JABLONSKI. U. S. Food, Drug and Insecticide Administration, New York. *J. Assoc. Official Agr. Chem.* 11, 434 8(1928); cf. *C. A.* 22, 121.—Attempts to sep. amaranth (I) from tartrazine (II) by a no. of different immiscible solvents and acid solns. proved unsuccessful. A no. of salts of org. bases ppt. I but have no effect on II, pseudocumidine sulfate being apparently the most effective; but complete pptn. of I could not be obtained, and moreover no pptn. could be obtained with concns. lower than 50 mg. of I in 20 cc. of soln. Attempts to split I into its components (naphthionic acid and "R" salt) by reducing with $SnCl_2$, and then isolating the less sol. component and weighing, showed that it is essential to have at least 50 mg. of I present, and the quant. yield was by no means satisfactory. Encouraging results were obtained by reducing with $SnCl_2$ (I gives naphthionic acid and "R" salt; II gives sulfanilic acid and phenylhydrazinesulfonic acid, which in turn is converted into sulfanilic acid by activated reducing agents, as well as into other org. compds. which do not enter into a subsequent dye combination), and then diazotizing and coupling the reduced product with a component that forms dyes of a soly. ratio different from those of I and II. On coupling with β -naphthol, naphthionic acid gives Fast Red A (S. & J. No. 102, Chem. Index No. 176), and sulfanilic acid gives Orange

II (S. & J. No. 86, Chem. Index No. 151), which can readily be sepd. by extg. their AmOH soln. with $1/512\text{ }N$ HCl. The exptl. procedure followed with a no. of different mixts. of I and II is described. When only small quantities of I are present, the Fast Red A produced should be detd. colorimetrically, and larger amts. can be titrated with $TiCl_3$.

A. PAPINEAU-COUTURE

A new procedure for determining tryptophan and tyrosine in proteins through the xanthoprotein reaction and its application to the most important proteins of our foodstuffs. J. TILLMANS, P. HIRSCH AND F. STOPPEL. Universitätsinstitut für Nahrungsmittel chemie Frankfurt a. M. *Biochem. Z.* 198, 379-401(1928).—This colorimetric detn. of tyrosine and tryptophan depends upon the xanthoproteic reaction specific for these amino acids. The reaction can be carried out even when these amino acids are components of the protein mol. without any preliminary hydrolysis. The color at 2 definite pH values is matched against that of a standard soln. contg. 50 mg. of *m*-nitrophenol (m. 96°) in 500 cc. $0.1\text{ }N$ NaOH. The color produced by 1 mg. *m*-nitrophenol in alk. media is taken as the unit of color intensity. The albumin + globulin of milk (human, cow, goat) show no differences but human milk contains more tryptophan and less tyrosine than the proteins of the other milks. Myosins from various meat sources show no appreciable difference in their tyrosine-tryptophan content. The proteins of wheat flour which are sol. in salt soln. have a high tryptophan content, while zein is lacking in tryptophan, thus confirming results obtained by earlier investigators. The tryptophan and tyrosine content of rye flour is so very different from that of the wheat flour that the two must not be regarded as similar. The tryptophan-tyrosine content of globulins from beans, peas and lentils varies between 1 and 2%. The water-sol. proteins (albumins) of important foodstuffs, with the exception of egg and blood albumins, have all a low tyrosine content (0.7-2.0%). Egg and blood albumin contain 4-5% tyrosine. The proteins of both animal and vegetable origin sol. in salt solns. have a low tyrosine content (0.7-2.0%). The important seed proteins (gliadins and glutenins) have a high tyrosine content (5-8%). S. MORGULIS

Studies in the proteins of Indian foodstuffs. II. The proteins of ragi (*Eleusine coracana*): Eleusinin, the alcohol-soluble protein. NUGGEHALI NARAYANA AND ROLAND V. NORRIS. Dept. Biochemistry, Indian Inst. Sci., Bangalore. *J. Indian Inst. Sci.* 11A, pt. 8, 91-5(1928).—Ragi is the staple cereal crop of the Mysore State and forms the greater part of the diet of the lower classes. Its food value is supposed to be approx. equal to that of wheat. The compn. is approx. ash 2.7, ether ext. 1.7, crude protein 8.4, crude fiber 3.4 and carbohydrates by difference 83.8%. The protein consists largely of a *prolamine* or EtOH-sol. protein named *eleusinin*. Eleusinin is sepd. by concn. of the EtOH ext. under reduced pressure until the first signs of pptn. are observed, filtered and poured with const. stirring into 10 times its vol. of distd. H_2O . An electrolyte such as NaCl ppts. the protein in flakes, sol. in 70% EtOH. Repeated soln. and repptn. are used to purify the protein. The dried, purified powder was defatted by the Soxhlet method. A light gray powder contg. about 15.9% N results. Eleusinin is insol. in dil. EtOH, gives pos. reactions for tyrosine and tryptophan, and neg. tests for P. Cystine is probably absent. The mean of 4 combustions gave C 53.29, H 7.35, N 15.91 and O 23.34. By using Plimmer's modification of the Van Slyke method for detg. N distribution in eleusinin, an av. of 3 detns. gave insol. humin 0.87, sol. humin 0.28, amide 20.52, basic (total) 5.93, arginine 2.60, histidine 2.69, lysine 0.64, total non-basic 71.16, amino 69.03 and non-amino 2.13. The totals make 98.76% of the N accounted for. The essential difference in N distribution between eleusinin and other prolamines is the lower content of basic N including the possible absence of cystine and a correspondingly high % of amino N. The work is being extended. C. R. FELLERS

Report on (the determination of) food preservatives. WYATT W. RANDALL. State of Maryland, Department of Health, Baltimore, Md. *J. Assoc. Official Agr. Chem.* 11, 429-33(1928); cf. C. A. 22, 121.—Results are given of a collaborative comparison of the present official A. O. A. C. method for Na benzoate in tomato ketchup, orange-juice concentrate, cider and crab-apple jelly, and of the proposed method previously described, which was modified by extg. with Et_2O instead of $CHCl_3$. A higher crude ext. was obtained with Et_2O than with $CHCl_3$, but this does not militate against the use of Et_2O if thorough drying and sublimation are used for purification. With the modified method (and probably also with the official method) the crude ext. contains material other than benzoic acid, sometimes in relatively large amt. When pains are taken to dry this residue thoroughly, the loss of wt. resulting from sublimation and the direct wt. of the sublimate itself will each serve as a detn. of benzoic acid, showing that sublimation serves an excellent purpose. Titration of a properly dried

and sublimed product should be the most accurate method for detg. benzoic acid. The official method usually yields results that appear better than they actually are, because acids other than benzoic are extd. by CHCl_3 , while the benzoic acid is not extd. completely, and when the quantity of such other acids is small the 2 errors may counter-balance each other.

A. PAPINEAU-COUTURE

Report on metals in foods: (determination of arsenic). W. F. CLARKE. U. S. Food, Drug and Insecticide Administration, Washington, D. C. *J. Assoc. Official Agr. Chem.* 11, 438-42(1928); cf. *C. A.* 22, 121.—Collaborative study of 4 modifications of the Gutzeit method, though it gave very good results in some instances, showed that not one of the various modifications of the Gutzeit method can be used by the av. analyst with the assurance or even probability that his results will be accurate, unless he attains considerable experience in its use. A volumetric method capable of detecting small quantities of As, subject to better control and simpler than the Gutzeit method, is highly desirable.

A. PAPINEAU-COUTURE

Report on (the determination of) glutenin in flour. M. J. BLISH. Agr. Expt. Station, Lincoln, Nebr. *J. Assoc. Official Agr. Chem.* 11, 475-8(1928); cf. *C. A.* 22, 122.—A collaborative comparison of the Blish-Sandstedt (*C. A.* 19, 1914), $\text{Ba}(\text{OH})_2$ (Blish, *C. A.* 22, 122) and Sharp-Gortner (*C. A.* 18, 3655) methods, directed by Coleman (*C. A.* 21, 3092), showed that the results are not as concordant as might be desired, which was partially due to a surprising variation in the figures for total protein. No preference is indicated for either method from the standpoint of probable accuracy, but the $\text{Ba}(\text{OH})_2$ is preferable from the standpoint of simplicity. A collaborative study of the $\text{Ba}(\text{OH})_2$ method, conducted by B., gave somewhat widely varying results (3.79-5.03, av. 4.31%), which may be partly due to the use of MeOH from different sources, as, if an appreciable quantity of ketones or aldehydes is present in the MeOH, they might react with certain chem. groups in proteins in such a manner as to alter their solubilities. In view of the findings of Csonka and Jones (*C. A.* 21, 2718) on the constituents of glutenin, the possibility of the variation of the relative proportions of α - and β -glutelins in glutenins should be investigated.

A. PAPINEAU-COUTURE

Report on (the determination of the) diastatic value of flour. F. L. TAGUE. Kansas State Agr. College, Manhattan, Kansas. *J. Assoc. Official Agr. Chem.* 11, 483-4 (1928).—Considerable work was done (details not given) on the detpn. of a uniform product from wheat starch which could be used as a substrate in detg. diastatic value, but the resultant products showed no improvement over the raw starch. Only 2 starches from other sources (not mentioned) showed improvement in uniformity of quality. Seven substances other than starches were investigated for substrates, and details are being worked out for 3 of these that give special promise.

A. P.-C.

Chemical enzymic studies of wheat flours. NELLY NEUENSCHWANDER. Biochem. Lab. Univ. Stockholm. *Biochem. Z.* 199, 445-50(1928).—In expts. with the methylene blue method it was found that flour by itself produces only slight decoloration. If either cozymase, *i. e.*, the activator of the mutase, or zymophosphate, *i. e.*, the H_2 donator, alone is added there is little change but if the 2 are added together the enzyme activity is greatly increased. The enzyme is apparently in the cells and is poorly dialyzable. The degree of decoloration or the amt. of oxido reduction enzyme present in flour depends upon the degree of milling. Likewise the enzyme activity differs in various flour samples, the Manitoba wheat flour having the greatest and the Swedish the least activity, while the other species of wheat show variable amts. in the order: Rosa Fé > Northern Spring > Australian. Respiration expts. with the same wheat flours do not yield results as regular as the methylene blue method and the variations by the 2 methods do not agree.

S. MORGULIS

Report on (the analysis of) cereal foods. F. C. BLANCK. Bur. of Chemistry and Soils, Washington, D. C. *J. Assoc. Official Agr. Chem.* 11, 458-64(1928); cf. *C. A.* 22, 122.—Discussion of the reports of the associate referees (see following abstrs.), with a selected bibliography of 31 references to articles published in 1926 and 1927.

A. PAPINEAU-COUTURE

Report on the sampling of flour. H. RUNKEL. U. S. Food, Drug and Insecticide Administration, Chicago, Ill. *J. Assoc. Official Agr. Chem.* 11, 464-70(1928); cf. *C. A.* 22, 122.—The method previously proposed was studied collaboratively by making H_2O detns. on samples taken by the same operator in different sacks in the same pile and taken by different operators in the same sacks. In sampling a single sack of flour, the method gave av. variations from the probable true moisture content approx. only 1.5 times the av. analytical variations, and in the majority of instances the sampling variations and analytical variations were practically the same. When sampling a

pile of sacks, the method gives reasonably close checks on 2 samples from the same pile taken by different operators.

A. PAPINEAU-COUTURE

Report on (the determination of) ash in flour. D. A. COLEMAN. Bur. of Agr. Economics, Washington, D. C. *J. Assoc. Official Agr. Chem.* 11, 470-5(1928); cf. *C. A.* 22, 122.—The use of alundum should be eliminated as a factor in the rapid ashing of flour because of the difficulty of obtaining const. wt. after ignition. Addn. of glycerol-alc. to flour to hasten ashing and prevent the formation of a hard carbonaceous mass with certain classes and grades of flour should be permitted. The use of 5% H_2O_2 , as proposed by Sullivan and Near (*C. A.* 21, 969) as an aid to rapid and satisfactory ashing, has no advantage over glycerol-alc., and the temp. (615°) to be used with this method is too high as it causes the ash to fuse. An av. difference of 0.072% was found in the ash content of straight-grade flour when ashed by the official A. O. A. C. method and the Dutch Govt. method (adding H_2SO_4 before ashing and multiplying the sulfated ash by 8/9).

A. PAPINEAU-COUTURE

Report on (the determination of) hydrogen-ion concentration of flour. C. H. BAILEY. Agr. Expt. Station, St. Paul, Minn. *J. Assoc. Official Agr. Chem.* 11, 478-81(1928); cf. *C. A.* 22, 123.—Collaborative study of the method using a H electrode gave more concordant results than the previous study, the coeff. of variation being 1.63%, as compared with 5.00% previously observed. Varying results were reported with heavily buffered solns., and B. considers that errors that arise in the detn. of the p_H value of flour are not attributable to difficulties inherent in the prepn. of the ext., but arise subsequently in the manipulation of the electrodes and the potentiometer. Fair agreement was obtained by 4 collaborators using the quinhydrone electrode; but in an extensive study using different types of electrodes B. and J. A. Dunn found substantially greater differences in duplicate detns. with the quinhydrone electrode than with the H electrode.

A. PAPINEAU-COUTURE

Report on (the determination of) gluten in flour. RAYMOND HERTWIG. Hecker H-O Co., Inc., Buffalo, N. Y. *J. Assoc. Official Agr. Chem.* 11, 481-3(1928); cf. Dill and Alsberg, *C. A.* 18, 3655; Coleman, *et al.*, *C. A.* 21, 2036.—Inquiries among competent cereal chemists and reference to the literature indicated that: (1) the gluten method is still used, but not as extensively as formerly; (2) it may give an idea of gluten quality, judged by an experienced and observing operator; (3) the quantities of the gluten ascertained by washing cannot be expressed in definite mathematical terms; (4) the quant. results are only approx. The general consensus of opinion seems to be that the chem. protein detn. is the best single test for gluten quality. A. P.-C.

Report on (the determination of) starch in flour. J. C. PALMER. U. S. Food, Drug and Insecticide Administration, Seattle, Wash. *J. Assoc. Official Agr. Chem.* 11, 484-7(1928); cf. Rask, *C. A.* 22, 123.—In the Rask method (*C. A.* 21, 1425), preliminary peptic digestion, as suggested by Hartmann and Hillig (*C. A.* 21, 287), considerably slowed up filtration and is liable to cause loss of starch since peptic activity and diastatic activity take place under the same conditions. Starch residues from whole wheat flours contained 0.102% N, equiv. to 0.58% protein. The drying time of 1.5 hrs. at 130° is ample to remove all H_2O . Because of the extreme hygroscopicity of the starch, the crucible contg. it should be well covered immediately on removal from the oven and kept covered while in the desiccator and during weighing. Contrary to common belief, the diastatic activity of flour is not destroyed by the preliminary washings with Et_2O and 70% $EtOH$, and delay during the H_2O washing may cause loss of starch through diastatic inversion. No appreciable hydrolysis occurs when the washed sample is allowed to stand 4 hrs. in contact with a few drops of 20.5% HCl ; and should it be necessary to introduce any delay during the operation, it should preferably be done at this point.

A. PAPINEAU-COUTURE

Report on (the determination of) fats, lipoids and lipid phosphoric acid (P_2O_5), water-soluble protein-nitrogen precipitable by 40% alcohol, and unsaponifiable matter in alimentary pastes, and unsaponifiable matter in flour. SAMUEL ALFEND. U. S. Food, Drug and Insecticide Administration, St. Louis, Mo. *J. Assoc. Official Agr. Chem.* 11, 490-7(1928); cf. *C. A.* 22, 123.—Results obtained by and comments on different methods for these several detns. as reported by collaborators are given. The acid hydrolysis method for fat again gave consistently higher results than direct extn.; the technic might advantageously be modified to allow weighing the sample directly into the extn. tube. Though the agreement between different collaborators with the present tentative A. O. A. C. method for lipoids and lipid P_2O_5 was not as close as might be desired, the method is believed to be the best available, and is recommended for adoption as official. In the official method for detn. of H_2O -sol. protein-N precipitable by 40% alc., filtration and washing of the pptd. protein are difficult and time-

consuming; this can be eliminated by detg. the precipitable N indirectly as the difference between total H_2O -sol. and non-precipitable H_2O -sol. N. In spite of the double chance of error introduced by making 2 N detns., practically the same results were obtained by the direct and indirect methods. 1.2% NaCl soln. is a better protein solvent than H_2O and exts. considerably more alc-insol. protein than the former; but since all authentic data bearing on the differentiation of egg yolk products from whole egg products (for which such methods were devised) are based on H_2O -sol. N, the NaCl soln. may be used for flour, but not for alimentary pastes. Comparison of the modified Kerr-Sorber and F. A. C. methods for unsaponifiable showed that the latter gave slightly higher results on the whole, the variation between different collaborators being about the same in both cases and too great to be satisfactory. A. P.-C.

Report on (the determination of) flour-bleaching chemicals. G. C. SPENCER. Bur. of Chemistry and Soils, Washington, D. C. *J. Assoc. Official Agr. Chem.* 11, 487-8(1928).—In the Seidenberg method (C. A. 20, 74) for the detn. of Cl in flour direct titration in presence of K_2CrO_4 indicator was not as satisfactory as the Volhard method. In the latter: (1) the pptd. AgCl was removed more satisfactorily by boiling and filtering than by using Et_2O for its coagulation; (2) better results were obtained with KCNS than with NH_4CNS ; (3) the HNO_3 used was rendered free from N oxides by adding $1/4$ its vol. of H_2O and boiling until colorless, which condition was preserved when the acid was kept in the dark; (4) 3 cc. of 1% $Fe_2(SO_4)_3 \cdot 9H_2O$ is most satisfactory as indicator. Ashing the extd. fat can be carried out in a porcelain crucible as well as in Pt dishes. The Rask method generally gives results about 20% lower than the Seidenberg method. In detg. total Cl in flour, ashing is best carried out by mixing with a mixt. of CaO, MgO and $Mg(NO_3)_2$, as in the Eschka method for S, but difficulty may be experienced in procuring CaO and MgO that are sufficiently free from Cl

A. PAPINEAU-COUTURE

Report on experimental baking tests (of flour). M. J. BLISH. Agr. Expt. Sta., Lincoln, Nebr. *J. Assoc. Official Agr. Chem.* 11, 488-90(1928); cf. C. A. 22, 2007. A brief and general account of the present status of the project. A. P.-C.

Studies on butter salts. O. F. HUNZIKER, W. A. CORDES AND B. H. NISSEN. *J. Dairy Sci.* 11, 333-51(1928).—Results of chem. and bacteriol. analysis of 10 leading butter salts are given, as well as the methods used. The usual small quantity of impurities found in high-grade salt had no effect on the quality of butter used. Even the addn. of relatively large amts. of impurities, such as 2% $CaSO_4$, 3% KCl, 1% $CaCl_2$, and 1% $MgCl_2$, failed to have any noticeable effect on the flavor of the butter.

J. C. JURRJENS

The approximate determination of butter and coconut fat in fat mixtures. THURE SUNDBERG. Lab. Stockholm Bd. Health. *Z. Untersuch. Lebensm.* 55, 397-404(1928). In Sweden not only pure margarine is sold but also margarines contg. 10-20% butter fat. Lab. methods for detg. butter fat in such products are presented. Tables and charts based on Reichert-Meissl and Polenske numbers made on exptl. mixts. of butter and coconut fat enable S. correctly to det. the % of these ingredients present in any given sample with very slight error. Cf. C. A. 22, 3793. C. R. FELLERS

The fatty acids of Egyptian butter fats. H. ATKINSON. *Analyst* 53, 520-30(1928).—The usual analytical methods involving the iodine no., Reichert-Meissl, Polenske, sapon., and refractive index values are not sufficient for the characterization of the purity of a sample of butter when it is not known whether the fat was obtained from the gamoos, cow, sheep or goat. Analyses based on the soly. of the water-insol. acids or of the nonvolatile acids also give results which leave much to be desired. It has been found, however, that when 1 g. of sapond fat is distd. with 210 cc. of water, the titration value of the non-volatile acids obtained by subtracting that of the volatile acids, expressed in mg. of KOH, from the sapon. no. is in general lower in butter fats of the sheep and goat than in those of the cow and gamoos. If the sum of the 2 values, oleic acid and acids insol. in 62% aq. alc., is subtracted from the non-volatile acids, a no. is obtained representing the *residual acids*, which is fairly const. for the butter fat of all these animals. Addn. of coconut oil or palm kernel oil has little effect on the non-volatile acids but decreases the sum of the 2 values referred to in this last sentence to an extent practically in proportion to the amt. added and the *residual acids* are increased by about 12 units for every 10% of added oil. Addn. of beef fat decreases the *residual acids* by about 2 units for every 10% of added fat but as this effect is comparatively small, the increase due to the presence of coconut or palm kernel oil is perceptible in a mixt. of the 2 with butter fat. The purity of the fat being established in this manner, the origin can be deduced from the Polenski and Reichert-Meissl ratio or the insol. Ag value.

W. T. H.

The detection of margarine in butter. H. P. STÄDLER. Public Research Board, Pforzheim. *Z. Untersuch. Lebensm.* 55, 404-5(1928).—The use of a *Litterscheid polarization microscope* is advocated as a rapid approx. method for the detection of starch and foreign fats. C. R. FELLERS

The Duclaux method* for the estimation of volatile fatty acids and its application to the estimation of butter fat in margarine. A. KNETEMANN. *Rec. trav. chim.* 47, 950-70 (1928).—The object of this investigation was to study the theoretical basis of Duclaux' method, and its applications in analytical work. It was found that the distn. curves of Duclaux are fully detd. by a special const., which has been called the "distn. value," C. A. formula was deduced theoretically in which the "distn. value" is expressed as a function of the quantity of acid obtained in a distn. fraction and the vol. of this fraction. Distn. values of formic, acetic, propionic, and valeric acids were calcd. from Duclaux' results, while those of pure butyric, caproic, caprylic, benzoic, and salicylic acids were experimentally detd. Figures given by Duclaux, Boekhout and de Vries for butyric acid are incorrect, as they used impure acid. A method was worked out for the estn. of butter fat in margarine based on the principle of Duclaux. On account of practical considerations it is to be preferred to make use of the empirical distn. figures found for butter fat and coconut oil instead of the distn. curves for pure butyric and caproic acids. Particulars in regard to practical operation are given in detail. It is shown that during sapon. at high temp. (180°), acids are formed which cause too high results: for this reason another sapon. method at lower temp. is suggested. The results of this method of analysis are more exact than those obtained by van der Laan's method, especially if abnormal coconut oils are used in manuf. J. C. JURRIJENS

Margarine indicators. G. PILAUDEAU, Société des Experts-Chimistes de France, AND E. VITOUX, Laboratoire Central du Ministère de l'Agriculture. *Ann. fals.* 21, 416-24(1928).—As a result of a competition, 2 suggestions were considered: addn. of 0.02% furfural and addn. of 0.05% of Fe or Ni stearate. It was found, however, that in both cases the addn. gave a disagreeable taste to the margarine. The Swedish Govt. having obtained satisfactory results with 0.2% starch, a study was made of the most suitable starch, its incorporation with the margarine, and its detn. so as to detect with certainty the addn. of 5% margarine in butter. Potato, maize and rice starches are equally suitable for the purpose. The starch is best added to the oil used in the margarine, the oil being stirred just before use to distribute the starch evenly. For the detn. of the starch, remove the fat by means of petr. ether, invert the starch with 2.5% H₂SO₄ by heating 3 hrs. on the water bath or 30 mins. at 110°, defecate, det. reducing sugars by Fehling's soln., and correct for the lactose present by detg. the latter separately. The technic is described in detail. To identify the starch, melt 50 g. at as low a temp. as possible on the water bath, remove the fat by repeated decantation with petroleic ether, centrifuge the aq. liquid strongly to throw down the starch and casein, decant, dehydrate with 5 cc. alc., remove the last traces of fat with Et₂O, dissolve the casein with warm 1% NH₃ and exam. the residue under the microscope. Addn. to butter of 1% of margarine contg. 0.2% starch can be detected with certainty. A. PAPINEAU-COUTURE

The simplified molecular constant (S. M. C.) and the freezing point of ewe's milk. R. MARTIN. Station Agronomique de Rodez. *Ann. fals.* 21, 390-7(1928).—The d., total solids, fat, non-fat solids, ash, casein, lactose, acidity, chlorides, S. M. C. and f. p. of the morning and evening milk of 48 individual ewes are tabulated. The results confirm those of Sajous (C. A. 19, 1300) and Andouard (Pharm. Thesis, Toulouse, 1922). The S. M. C. found (73-84.6, av. 80.5) is appreciably higher than that of cow's milk (70-9, av. 73-4). Since, except under pathological conditions, the milk serum and blood serum of a given individual animal are isotonic, the f. p. of ewe's milk (-0.58 to -0.63°, av. -0.61°) is lower than that of cow's milk (-0.55 to -0.56°) as expected. The original acidity is higher than that of cow's milk, as was to be expected from the higher casein content (cf. Bordas and Touplain, C. A. 5, 2873). A. P.-C.

Milks of the department of Orne (region of Sées): true and apparent simplified molecular constant (S. M. C.) L. BLEUQ. *Ann. fals.* 21, 398-410(1928).—The d., acidity, total solids, lactose, fat, casein, ash, chlorides and true and apparent S. M. C. of 169 milks are tabulated and show that the compn. of the milks of this region is normal. A. PAPINEAU-COUTURE

Methylene blue for the milk reductase test. D. W. STEWART. *Analyst* 53, 532(1928).—One Blauenfeldt and Tvede methylene blue tablet dissolved in 200 cc. of water gives a soln. such that 1 cc. is suitable for 40 cc. of milk. Slight differences in the strength of the dye soln. do not have much effect on the test. W. T. H.

The influence of the *p*_H of agar media upon the bacterial counts of raw and pas-

teurized milk. JACK FABER. *J. Dairy Sci.* **11**, 401-3(1928).—Expts. were conducted on 100 samples each of raw and pasteurized milk, and 5 of each plated in dilns. of 1:100, 1:1000, and 1:10,000 each week. Agar of p_H values of 6.2, 6.4, 6.6, 6.8 and 7.0 were prepd. every 2 weeks for plating. The results obtained by plating 99 samples of raw milk showed but little variation in counts. The medium having a H-ion concn. of 6.8 gave the highest av. bacterial count. The other media ranged as follows: 6.6, 6.4, 6.2 and 7.0. The results obtained by comparing the results of 100 samples of pasteurized milk plated on beef ext. agar showed but little variation. The medium having a H-ion concn. of 6.4 gave the highest av. bacterial count; the others ranged in the following order: 6.6, 6.8, 7.0 and 6.2. Conclusion: If the bacterial counts of raw and pasteurized milk, plated on beef ext. agar, are significantly affected by the H-ion concn. of the media, when ranging between 6.2 and 7.0, the 100 samples are not sufficient to show this significance. J. C. JUURJENS

Preservative tablets and preserved milk samples. L. M. LAMPERT. *Monthly Bull. Dept. Agr. California* **17**, 449-53(1928).—Analyses of 11 tablets representing the product of 4 manufacturers showed $HgCl_2$ to be the effective preserving agent in each case. Milk samples were not always completely sterilized by these tablets. Milk preserved with $HCHO$ in the diln. used showed much greater bacterial growth than milk preserved with $HgCl_2$ tablets. A finely divided ppt. or curd was present in all of the samples which had been preserved with $HgCl_2$. This appeared to be of consequence in one case only, in which citric acid was a constituent of the tablet. There was a slight decrease in the percentage of fat when detd. on preserved samples, from that found when detd. on fresh samples. This decrease was greater when $HgCl_2$ was used as the preservative. L. W. RIGGS

Some observations on the consistency of cream and ice cream mixtures. GEORGE M. BATEMAN AND PAUL F. SHARP. *J. Dairy Sci.* **11**, 380-96(1928). The yield value and consistency of cream increased with fat content, aging and homogenization, while it decreased by heating. Ice cream mixts. of av. compn. vary considerably in yield value and consistency. Some of the difficulties are shown, which may arise if plastic substances are treated as viscous. Attention is called to some of the difficulties in relating the "viscosity" of ice cream mixt. to their freezing properties. J. C. J.

Report on (the analysis of) eggs and egg products. J. C. PALMER. U. S. Food Drug and Insecticide Administration, Seattle, Wash. *J. Assoc. Official Agr. Chem.* **11**, 421-3(1928); cf. *C. A.* **22**, 282; Lepper, *C. A.* **22**, 121. Detn. of H_2O in dried eggs by heating in vacuum at 100° gives consistently higher results than by heating in vacuum at 55° . Comparative detns. of N and lipoids in the product after drying at 55° and at 100° showed that little, if any, loss of N or lipoids occurs at the higher temp. As the xylene-distn. method gives results quite comparable to those obtained by the 100° vacuum method, it would seem that drying in vacuum at 55° fails to remove all the H_2O present. A. PAPINEAU-COUTURE

Report on (the determination of) water-soluble protein, unsaponifiable matter and ash in eggs. SAMUEL ALFEND. U. S. Food, Drug and Insecticide Administration, St. Louis, Mo. *J. Assocn. Official Agr. Chem.* **11**, 424-7(1928). Work was done only on the development of a satisfactory method for the detn. of ash, and the following conclusions were reached: (1) Ashing of solid or liquid eggs without any previous treatment is impracticable and yields low results. (2) Addn. of 60-mesh alundum reduces the ashing time by 75%. (3) Addn. of $Mg(OAc)_2$ soln. gives higher ash, indicating that in the absence of an excess of basic material some inorg. matter is lost by volatilization. (4) Addn. of $Mg(OAc)_2$ soln. prevents the creeping of the material up the sides of the ashing dish during the charring. (5) SiO_2 dishes are markedly corroded by MgO , and particularly by granulated Al_2O_3 , during ashing. (6) Pt dishes do not appear to be attacked by egg ash in presence of Al_2O_3 and an excess of MgO . (7) Porcelain crucibles are not attacked by MgO or Al_2O_3 on ignition at low red heat. A. PAPINEAU-COUTURE

Report on the detection of decomposition in eggs. H. I. MACOMBER. U. S. Food, Drug and Insecticide Administration, New York. *J. Assocn. Official Agr. Chem.* **11**, 427-8(1928); cf. *C. A.* **22**, 121.—Further collaborative results on the detn. of acidity in the fat of dried eggs gave excellent results. A. PAPINEAU-COUTURE

Comparative acidimetric investigations on seven meat extracts, seasonings and similar products. PAUL HIRSCH AND JOSEPH KIESGEN. Food Chem. Inst., Frankfurt-on-Main. *Z. Untersuch. Lebensm.* **5**, 415-23(1928).—The p_H , acidity and formol titration curves were detd. on various samples of meat and soup exts. and also peptone. In soup flavorings the protein was greatly broken down by deep-seated hydrolysis. Between p_H 7 and 11.6, there were 11 atoms of N to each 7 acid groups. Though

there is a general similarity in the titration curves for the several products examd., those for peptone and ext. were much smoother and more uniform than those developed from the soup-flavoring substances.

C. R. FELLERS

Report on (the determination of protein in) meats and meat products. R. H. KERR. Bur. of Animal Industry, Washington, D. C. *J. Assocn. Official Agr. Chem.* 11, 507-13(1928); cf. *C. A.* 22, 125.—Results of numerous tests show that digestion of 2-4 hrs. with an elec. heater (Gilmer), and to a less extent with a Bunsen burner, frequently gives rise to a considerable loss of N. With the elec. heater, highest results were obtained when an asbestos guard was used to prevent contact of the flask with the curved inner surface of the bowl-like depression in the upper brick of the heater and leave the flask about 1 in. above the coils.

A. PAPINEAU-COUTURE

Report on (the determination of) crude fiber in cacao products. MARIE L. OFFUTT. U. S. Food, Drug and Insecticide Administration, New York. *J. Assocn. Official Agr. Chem.* 11, 514-6(1928).—The present A. O. A. C. method for crude fiber in cacao products is somewhat defective because the quantity of sample used varies according to the amt. of sugar and other substances added during manuf. It has been modified by operating on a 2-g. sample consisting of the Et_2O -, H_2O - and alc.-insol. material, and the technic of the modified method is given in detail. The results obtained by the modified method seem to show greater variations for shell material and nib material than those obtained by the usual method. The modified method is applicable to cocoa, bitter liquors and sweet liquors; but in its present form it is not applicable to milk chocolates.

A. PAPINEAU-COUTURE

Report on (the detection of adulteration of) cacao butter (and milk chocolate). WALTER F. BAUGHMAN. Bur. of Chemistry and Soils, Washington, D. C. *J. Assocn. Official Agr. Chem.* 11, 517-20(1928); cf. *C. A.* 20, 118.—The test previously described for the detection of coconut oil and palm kernel oil in cacao butter is not suitable in the presence of milk fat, as the latter contains caproic, caprylic and capric acid glycerides. A collaborative study showed that the test can be made satisfactory for milk chocolate fat by using as a blank a mixt. of cacao butter and milk fat in the proportions in which they occur in the fat sepd. from the milk chocolate product under examn., the milk fat content being calcd. approx. either from the lactose or casein contents.

Report on (the analysis of) fruits and fruit products. H. J. WICHMANN. U. S. Food, Drug and Insecticide Administration, San Francisco, Calif. *J. Assocn. Official Agr. Chem.* 11, 442-4(1928); cf. *C. A.* 22, 121.—A brief discussion of the work done by members of the Assocn. during 1927 (cf. next abst.; also Hartmann and Hillig, *C. A.* 21, 2451).

A. PAPINEAU-COUTURE

Report on (the determination of) ash (constituents) in fruit products. DORIS H. TILDEN. U. S. Food, Drug and Insecticide Administration, San Francisco, Calif. *J. Assocn. Official Agr. Chem.* 11, 445-8(1928); cf. *C. A.* 22, 122.—In the scheme of analysis previously suggested, the MnO_2 pptd. by AcONa-Br in the detn. of CaO and MgO can be used for the detn. of Mn, both the gravimetric and the colorimetric periodate methods giving satisfactory results for such small quantities as are usually found in the ash of plant material. The present official A. O. A. C. procedure in the Lindo-Gladding method of washing K_2PtCl_6 with 80% alc. causes a slight error (which may be quite appreciable with the small quantities of K_2O that may be encountered in plant material) due to the soly. of the ppt.; but this error is eliminated by using exclusively a 90% alc. wash soln.

A. PAPINEAU-COUTURE

The available carbohydrate content of some fruits and vegetables. MARION BELL, M. LOUISA LONG AND ELSIE HILL. Potter Metabolic Clinic, Santa Barbara. *J. Metabolic Research* 7-8, 195-7(1925-6).—The percentage of available carbohydrate in canned vegetables was as follows: asparagus 1.8, lima beans 7.5, string beans 0.57, stringless beans 0.67, corn 9.7-14.8, peas 5.4, pumpkin 3.0-5.0, rhubarb 1.3, spinach 2.4, and tomatoes 2.6-3.0. In canned fruits the following values were obtained: apricots 5.5-7.0, blackberries 4.2-5.5, raspberries and strawberries 5.0, cherries 4.8-5.5, grapefruit 6.1, peaches 4.0-5.8, pears 4.1-5.1, pineapple 8.0-10.7 (20.0% in one variety); and quince 4.3. In the edible portion of fresh fruits and vegetables the available carbohydrate was: artichokes 4.1, avocado 1.5, barle-de-capucin 0.6, cassaba melon 8.3, cauliflower stalk 3.0, chard 1.0, chenopodium 0.2, chiote 1.9, cucumber 1.7, grapefruit 5.3, guavas 6.4, kale 2.0, loquats 5.6, honeydew melon 7.0, mustard greens 0.0, dark red osach 0.2, patience 0.6, phytin 0.6, purslane 0.3, *Scolymus Hispanicus* 0.3, banana squash 6.2, yellow squash 2.2, winter squash 2.5, summer squash 8.0, zucchini 2.1, and witloof, 0.5. Unwashed bran contained 27.3% available carbohydrates, cacao

13.9, cacao shells 0.14, coffee (dry) 11.0, ginger ale 10.0, Roman meal 41.9 and rye meal 56.3.

H. J. DEUEL, JR.

Changes in composition during ripening and storage of melons. J. T. ROSA. University of California. *Hilgardia* 3, 421-43(1928).—The late stages of development and the ripening process in cantaloupes, Honey Dews, Casabas, and watermelons are characterized by the following changes when the fruits remain attached to the plant: progressive increase in per cent of total solids, in total sugar content, in sol. solids, and in sp. gr. of the juice. Reducing sugars, which consist of approx. equal proportions of levulose and dextrose, decrease in amt. during ripening, being partly used in respiration, and partly changed to sucrose. Sucrose increases more rapidly than reducing sugars decrease, showing that sugars are moving into the fruit until the full-ripe stage is reached. The total amt. of pectic substances remains about the same, but the amt. of protopectin, high in unripe melons, decreases rapidly during ripening, with a corresponding increase of pectic substances in sol. form, suggesting that partial disintegration of cell walls is an important part of the ripening process. The flesh becomes progressively sweeter and softer, and the rind turns from green to yellow. Fruits which are picked from the plants in the immature condition show the following changes during the storage at ordinary temps. (70°-75°): little or no increase in sugar content, in the early part of the storage period, and generally a small decrease in sugars, during the latter part of storage, due to the losses occasioned by respiration. Honey Dews and Casabas during storage show the same change in form of sugars as do fruits attached to the plant, *i. e.*, decrease in reducing sugar and increase in sucrose. The total content of pectic substances decreases slightly, and protopectin is changed to pectin, just as in fruit attached to the plant. The flesh becomes softer, but does not gain appreciably in sweetness; hence melons picked very immature, while the sugar content is low, upon artificial ripening become soft and to some extent juicy, but do not attain good flavor because of the lack of sugar. Fruits of Honey Dew and Casaba picked slightly unripe and exposed to ethylene at the rate of 1 pt. to 2000 of air, or 1 pt. to 4000 of air, for 2 to 5 days, show no increase in sugar content, but do show a marked acceleration in the rate of softening, in change from green to yellow color of the rind, and in conversion of reducing sugars to sucrose, compared to similar fruit stored without ethylene treatment. The effects of ethylene upon the ripening process are believed to be due to activation of enzymic reactions, and bring about changes in a short time that would ordinarily require a longer period.

J. J. SKINNER

The iodine content of Cape Cod cranberries. FRED. W. MORSE. Mass. Agr. Expt. Sta., Amherst Univ. *J. Biol. Chem.* 79, 409-11(1928). The I content of cranberries from crates, Sandy Neck and Nantucket were 26, 35 and 27 parts per billion, resp.

ARTHUR GROLLMAN

Artichokes. FRANK T. SHUTT. Dept. Agr. Canada, *Rept. Dominion Chemist.* Year Ending March 31, 1927, 53-4(1928).—Analyses of the combined stalks and leaves and of the tubers of artichokes (*Helianthus tuberosus*) gave H₂O 74.26, 73.23; crude protein 2.61, 2.33; crude fat 0.65, 0.13; carbohydrates 13.19, 21.46; fiber 5.70, 1.23; and ash 3.59, 1.62%, resp. The compn. of the stalks and leaves is very similar to that of the sunflower plant cut at an early stage of growth. The nutritive value of the artichoke as a stock food has not been definitely detd.

K. D. JACOB

The iodine number of Spanish paprika oil. LLOYD C. MITCHELL AND SAMUEL ALFEND. U. S. Food, Drug and Insecticide Administration, St. Louis, Mo. *J. Assocn. Official Agr. Chem.* 11, 523-7(1928); cf. *C. A.* 21, 289. —The I no. of 11 authentic samples of Spanish paprika grown in various districts in Spain in 1927, detd. by the previously described method, varied from 133.0 to 139.7, the lowest I nos. being obtained in the samples with the largest proportion of seeds, and therefore of oil. The I no. range (125-36) for paprika oil specified in the U. S. food standards is therefore not applicable when the CHCl₃-extn. method is used.

A. PAPINEAU-COUTURE

Examination of three caffeine-reduced (so-called decaffeinated) coffees. P. N. LEECH. Am. Med. Assoc. Lab. *J. Am. Med. Assocn.* 91, 880-3(1928).—The amt. of caffeine removal in com. samples of Kaffee Hag and Sanka was well over 90% if it is assumed that 1.2% of caffeine by wt. was originally present. The statement that 90 or 97% of the caffeine has been removed is meaningless unless the amt. originally present is declared. Routine checking of each batch of material is necessary and has been adopted by the Kaffee Hag and Sanka corporations. Blanke's Refined Health Coffee contains a relatively large amt. of caffeine notwithstanding the claim that 90% of the caffeine has been removed.

L. W. RIGGS

Report on (the analysis of) flavors and non-alcoholic beverages. J. W. SALE. U. S. Food, Drug and Insecticide Administration, Washington, D. C. *J. Assocn. Official*

Agr. Chem. 11, 503-7(1928); cf. *C. A.* 22, 124.—The steam distn. method gave acceptable results with oils of orange, lemon and limes dissolved in corn and cottonseed oils; with nutmeg and peppermint oils the errors were -3% to $+3\%$, and -7 to $+4\%$, resp. Collaborative results obtained in the colorimetric and gravimetric detn. of methyl-anthranilate showed rather wide deviations from the av., which may be due to the fact that with both methods experience is required to obtain acceptable results. S. considers the results reported sufficiently satisfactory to warrant adoption of both methods as official. The precautions required in the colorimetric method are briefly given.

A. PAPINEAU-COUTURE

Effects of atmospheric germs on household beverages. (Miss) R. DUFLOS. *Chimie et industrie Special No.*, 834-41(April, 1928).—A brief general discussion of the good and bad effects of atm. germs on water, milk, wine, cider and beer. A. P.-C.

The question of alcohol. JULES AMAR. *Compt. rend.* 187, 511-2(1928).—The alc. of wine or beer in very moderate doses is a thermogenic food which may constitute a certain fraction of the diet in winter. Alc. furnishes no muscular or nervous energy.

L. W. RIGGS

Industrial applications of p_H : cure for the blackening of canned Crustaceae. R. LEGENDRE. Office National des Recherches et Inventions. *Chimie et industrie Special No.*, 842(April, 1928); cf. *C. A.* 20, 3199.—Blackening can be prevented, and at the same time the flavor preserved or improved, by adjusting the p_H of the finished product to approx. 6, e. g., by addn. of AcOH, CO_2 , citric, lactic or tartaric acids, or acid condiments.

A. PAPINEAU-COUTURE

Curious case of antimony poisoning. J. T. DUNN. *Analyst* 53, 532-3(1928).—A lemonade powder contg. sugar, tartaric acid and $NaHCO_3$ was dild. with water and kept overnight in enameled buckets. Next day some 50-60 people who drank the lemonade were made sick. The enamel contained 2.88% of Sb_2O_3 , 19.6% Na_2O , 20.43% B_2O_3 and 39.48% SiO_2 . Other Sb_2O_3 enamels were not attacked by the same lemonade.

W. T. H.

The iron and manganese content of feeding stuffs. J. T. SKINNER AND W. H. PETERSON. Univ. of Wisconsin. *J. Biol. Chem.* 79, 679-87(1928).—The Fe and Mn contents of a no. of feeding stuffs were detd. The Mn content ranged from 5.4 mg. per kg. (yellow corn) to 712.4 mg. (field sugar beet tops). The Fe content ranged from 8.9 (polished rice) to 750 mg. per kg. (coconut oil meal).

ARTHUR GROLLMAN

The sunflower. C. D. TIMSON. Rhodesian Ministry of Agr. & Lands. *Rhodesia Agr. J.* 25, 281-96(1928).—Ash of sunflower heads, stems and leaves contained P_2O_5 0.98, K_2O 28.90 and CaO 12.00%. Air-dried leaves gave the following analysis: H_2O 14.87, fat 2.82, protein 16.50, carbohydrates 42.15, crude fiber 7.87, and ash 15.79%. The nutritive ratio is 1:2.9. Sunflower heads without seeds and sunflower meal made from heads contg. about 8% ripe seeds contained H_2O 11.73, 14.00; ether ext. 3.18, 5.86; protein 8.86, 8.84; carbohydrates 46.42, 29.70; crude fiber 18.19, 31.70; and ash 11.62 and 9.90%, resp. The nutritive ratios are 1:6.04 and 1:8.5, resp. Silage made from sunflowers was richer in protein and fat but poorer in carbohydrates than maize silage. The starch equiv. is lower and it is less palatable than corn silage.

A. L. MEHRING

Wild sunflower. FRANK T. SHUTT. Dept. Agr. Canada, *Rept. Dominion Chemist*, Year Ending March 31, 1927, p. 53(1928).—Two samples of wild sunflower from Saskatchewan contained H_2O 81.30, 81.30; crude protein 2.92, 2.88; crude fat 0.77, 0.75; carbohydrates 9.09, 8.83; fiber 3.47, 3.85; and ash 2.45, 2.39%. The samples were taken as the seeds were just beginning to form. The protein content is higher and the fiber content lower than in the cultivated sunflower. If this plant is found to be satisfactory from the standpoint of palatability and yield it may develop into a useful forage crop in semi-arid areas.

K. D. JACOB

The curing of hay with salt. FRANK T. SHUTT. Dept. Agr. Canada, *Rept. Dominion Chemist*, Year Ending March 31, 1927, p. 55(1928).—Expts. were carried out on the curing of hay with salt from the deposits at Malagash, N. S., to det. whether the preservative action of the salt would permit of damp hay being stored without molding and whether the presence of the salt would prevent spontaneous combustion of the hay. Analyses of the salted hays did not reveal any outstanding chem. characteristics but the salted hay had a better color and aroma, and a higher % of attached leaves and was less dusty than the unsalted material. Addn. of as much as 20 lb. salt per ton of hay had no bad effect on the health of the cattle, but 30 lb. per ton had a slight purgative action. The expts. are being continued.

K. D. JACOB

The "Sugar Jack" process. FRANK T. SHUTT. Dept. Agr. Canada, *Rept. Dominion Chemist*, Year Ending March 31, 1927, pp. 51-2(1928).—By use of a "con-

verter" it is claimed that an excellent silage may be prepd. from such roughages as stalks, vines, straw, clover threshings, etc. Expts. showed that, although by means of this process a hard, coarse roughage may be presented to the animal in a moist, soft and warm condition, with its palatability enhanced by a slight saltiness, the food value of the original material is not improved by the treatment. An analysis of the "converter" used in the process gave NaCl 75, hydrated dolomitic lime 23 and vegetable matter 2%. K. D. JACOB

Occurrence of As in fish (SADOLIN) 11I. Farm or field roots [nutritive value of mangels] (SHUTT) 28. The general occurrence of Au in foodstuffs (BERG) 11A. Treatment of organic wastes (WEAVER) 14. Apparatus for drying or cooling flour (U. S. pat. 1,690,013) 1. Phosphate in small spherical particles [for use in baking powder] (U. S. pat. 1,689,697) 18. Specific gravity registers for milk flowing through dispensing apparatus (U. S. pat. 1,689,658-9) 1. Cellulose from straw, cornstalks, etc. (Brit. pat. 286,211) 23. Glass-coated pipe coil suitable for heat exchange between foods, etc., and heating agents (U. S. pat. 1,689,435) 1.

Food product. IRVING S. MERRELL (to Merrell-Soule Co.). U. S. 1,689,357, Oct. 30. The manuf. of self-sustaining pieces or blocks of compressed baked milk powder is described.

Bleaching foods. WM. B. STODDARD and VAMAN R. KOKATNUR (to Pilot Laboratory, Inc.). U. S. 1,687,803, Oct. 16. Food materials such as flour are bleached with peroxidized products of acids such as occur in natural fats and oils, e. g., fatty acid peroxides made from coconut oil. U. S. 1,687,804 specifies treating flour or other material to be bleached with an org. peroxide compd. such as acetyl, fumaryl and succinyl peroxides and with fatty acid peroxides or other suitable activating per-compd. which increases the effectiveness of the bleaching agent. U. S. 1,687,805 specifies treating flour or other material to be bleached with a peroxidized compd. of a fatty acid or ester or other peroxidized compd. constitutionally similar to the vehicle of the coloring matter in the material to be bleached.

Preserving foods. G. VAN DER VEEN and G. J. P. H. A. DEBEUS. Brit. 286,006, March 14, 1927. Fruit, meat, vegetables or other foods are preserved by coating with a mixt. of paraffin and colophony in such proportions as to have a m. p. of about 25-30°. Powd. charcoal or other suitable form of C may be added, as may also MgO, MgCO₃, MgCl₂ and soda. The articles of food may be treated with an acid permanganate soln. before being coated.

Dried milk and other preparations. CARL KNOCH and FRITZ GROSS. Fr. 638,341, July 28, 1927. See Brit. 285,313 (C. A. 22, 4670).

Chocolate milk composition. WILBERT A. HEYMAN. U. S. 1,689,028, Oct. 23. Cocoa powder of low fat content is mixed with water and the mixt. is heated to a temp. sufficiently high to break up the starch cells of the cocoa, homogenized, mixed with NaHCO₃ and milk and the mixt. is sterilized or pasteurized and dehydrated to obtain a powd. product. U. S. 1,689,029 also relates to similar products.

Apparatus for extracting juice and pulp from fruit and vegetables. SOLER ET SAUNIER. Fr. 637,954, Nov. 25, 1926.

Albuminous compounds from waste liquors obtained in meat treatment. LABORATORIUM TASCH A.-G. Brit. 286,208, Feb. 28, 1927. Albuminous compds. are obtained from the waste liquors produced in salting processes for preserving meat, by adding guaiacolsulfonic acid or other suitable org. sulfonic acid or H₂SO₄ as long as a ppt. is formed.

Invertase preparation from yeast. LEONARD WICKENDEN (to John J. Naugle). U. S. 1,689,607, Oct. 30. Yeast is heated with a sugar sirup having a pH of about 4 to about 5 at a temp. of about 55-65° to obtain a prepn. which is suitable for use in making edible products.

Treating grain, seeds, fruits, nuts, etc. NAAMLÖÖZE VENNOOTSCHAP INTERNATIONALE OXYGENIUM MAATSCHAPPIJ NOVADÉL. Brit. 285,850, Feb. 23, 1927. Acid solns. of SO₂ or its derivs. such as sulfites are used and subsequently neutralized or oxidized.

Animal food. TOWARZYSTWO HANDLOWO-PRZEMYSŁOWE "ALBUMINA." Fr. 638,187, July 25, 1927. Lupine seeds are crushed and treated to remove their bitterness, mixed with molasses and dried at 35-45°. The product is suitable for feeding animals.

Preserving fodder. M. FLUBACHER. Brit. 285,939, Oct. 22, 1926. A 3% soln. of a mixt. formed of NaCl 50, CaCl₂ 10, Na phosphate 10 and ferrous lactate 30 parts

is used for spraying materials such as clover, vetches or maize when fresh cut and before packing down in an air-tight container. The material may be packed in successive layers.

13—GENERAL INDUSTRIAL CHEMISTRY

Scientific organization in chemical manufacturing plants. CHRISTO CASACOF. *Chimie et industrie* Special No., 924-5 (April, 1928).—A brief discussion of economic, technical and commercial organization of the prepn., manuf. and sales organization of chem. plants. A. PAPINEAU-COUTURE

Heat economy processes in the technical chemical industry. HANS BRANDT. *Kautschuk* 4, 149-51 (1928).—A review and discussion. C. C. DAVIS

Economic aspects of industrial research and development. L. V. REDMAN. Bakelite Corporation, Bloomfield, N. J. *Ind. Eng. Chem.* 20, 1242-4 (1928).—By 2 series of graphs the probable course of earnings on a conservative investment (5% per annum), from a competitive industry ($12\frac{1}{8}\%$ per annum), and from a noncompetitive industry ($33\frac{1}{8}\%$ per annum), all on a (a) simple interest or without-reinvestment basis, and a (b) annual reinvestment of income or earnings basis, is shown. Similarly the probable liquidation bases of the projects are shown, and the optimum conditions for success and failure discussed. W. C. EBAUGH

Certain aspects of occupational arsenicism in the chemical industry. E. AGASSE-LAFONT, A. FEIL AND F. HEIM DE BALSAC. *Chimie et industrie* Special No., 945-6 (April, 1928).—A brief summary of the results of an as yet unpublished investigation into occupational arsenicism. In the manuf. of As_2O_3 by oxidation of As_2O_3 by HNO_3 , there is little or no infection, or at most only slight manifestations. The handling of Na_3AsO_4 in its recovery from the manuf. of anilarsinic acid, however, was found to be much more dangerous. The clinical symptoms of the intoxication are described. The difference in hazard between these 2 mfg. processes is attributed to the fact that the liquors handled in the recovery of Na_3AsO_4 are alk. and easily penetrate through the fats protecting the teguments, while the acid liquors of the oxidation of As_2O_3 are repelled by these fats. A. PAPINEAU-COUTURE

Factors in modern methods of pulverizing. HARLOW HARDINGE. *Ceramic Industry* 11, 166-9 (1928).—Comments are made on the advantages and disadvantages of various types of mills. Mill capacity and economy can be greatly increased if operated so as to allow about 25% of the unfinished product to be discharged with the finished product. A new type of pebble mill is described in which the finished product is continuously removed together with a small quantity of unfinished product by means of air circulating in a closed system. The oversize product is automatically sepd. and returned to the mill. By proper control of the air current the degree of fineness may be controlled. Another advantage claimed is the removal of moisture by the air, thus preventing packing. Operating data are given. W. H. RISING

Wetting agents and emulsifiers. A. NOLL TILSIT. *Chem. Techn. Fabrikant* 25, 95-7, 99-100 (1928).—A discussion of the properties and constitution of 22 trade prepsns. P. ESCHER

Factory floors. F. HERON ROGERS. *Chemistry and Industry* 47, 1011-21 (1928). E. H.

Gaging; a neglected chemical hazard. J. H. SHAPLEIGH. *Chem. Markets* 23, 359-62 (1928).—Instead of being merely a routine operation in chem. plants, gaging calls for care and thought, not only for the sake of accuracy but also to prevent accidents to property and persons. Proper equipment, procedure, personnel, thorough schooling in the operations involved, etc., are necessary. Illustrations of hazards and methods for guarding against them are given. W. C. EBAUGH

Automatic control through temperature or pressure. C. J. SWAN. Am. Radiator Co., 40 West 40th St., New York, N. Y. *Ind. Eng. Chem.* 20, 1152-5 (1928).—The "Mercoïd Control" is described. Its essential element is the design of an elec. switch which makes and breaks contacts, depending upon changes in temp., vacuum or pressure.

It consists of a glass tube in which are sealed leads of a special material. The circuit is made or broken by a small quantity of Hg when the tube is tilted. Arcing is instantly stifled or dampened by inert gases which are sealed hermetically within the tube. Operation with safety is thus possible, where there are fumes or other hazardous conditions. Since there is no corrosion or oxidation the contact is instantaneous in operation, and the contact points remain clean. The control will carry 110 or 220 v. with sufficient amperage in most cases to operate elec. motors up to a capacity of 1 h. p. By proper connection with suitable standard devices temps. and pressures can be controlled at will. Many illustrations of applications to chem. industries are cited.

W. C. EBAUGH

Washing by decantation. G. EVERETT MARSH. *Ind. Eng. Chem.* 20, 1241(1928)
—A chart is presented from which can be detd. the no. of decantations necessary to reduce the impurities in a ppt. to a given amt., the no. of washings required, the quantity of wash-water needed, etc. It is based upon the relation $C_n = (V_1/V_0)^n C_0$, where C_0 = the initial concn. of the impurity, C_n = its concn. after the n th washing, V_0 = vol. of vessel in which the washing is carried out, and V_1 = vol. of the settled ppt.

W. C. EBAUGH

Isotherms and isobars for air separation studies. BARNETT F. DODGE. Dept. Chem. Eng., Yale Univ., New Haven, Conn. *Chem. Met. Eng.* 35, 622(1928). Studies of processes for air sepn. by liquefaction methods must be based upon pressure-temp.-compn. data for solns. of O and N. From Dodge's paper (cf. *C. A.* 21, 1732) certain data have been compiled in order that greater use may be made of them in engineering calcns. Table I gives vapor compn. and pressure as a function of liquid compn. at various const. temps., and Table II gives the vapor compn. and temp. as a function of liquid compn. at various const. pressures.

W. C. EBAUGH

The work of the exceptionally gifted student in chemical engineering (OLSEN) 2. Micro-determination of lead (diagnosis of Pb poisoning) (SEISER, *et al.*) 11B. Plastic moldable composition containing rubber [suitable for electric insulation] (U. S. pat. 1,658,500) 30. Separation of gases by liquefaction [H from coke oven gas or lighting gas] (Fr. pat. 638,382) 13.

PAUER, W.: **Energiespeicherung.** Dresden and Leipzig: Th. Steinkopff 176 pp. M. 12 (paper), M. 13.50 (bound). Reviewed in *Chimie et industrie* 20, 599 (1928).

Exothermic reactions. I. G. FARBENINDUSTRIE AKTIENGESELLSCHAFT. Fr. 636,338, May 13, 1927. To prevent excessive heating in exothermic reactions an indifferent solid substance is added to the reagents. The size of the granules of the added substance is sufficiently different from that of the reaction product to allow of sepn. by sifting.

Colloidal solutions. M. POLANYI and S. VON BOGDANDY. Brit. 286,316, March 4, 1927. Finely distributed substances insol. in one another are obtained by vaporizing one substance and condensing it *in vacuo* on the surface of a liquid body of the other substance. An app. is described.

Emulsions. F. BRÄUNLICH. Brit. 285,880, Feb. 24, 1927. Mono- or di glycerides of the higher fatty acids or their mixts. with tri-glycerides or compds. of polyglycerides with fatty acids are stated to be suitable for prepg. aq. emulsions and may be used with fats, fatty alcs., higher ketones, wool grease resins, ethereal oils, satd. or unsatd. hydrocarbons or naphthenes. Glycerol and milk may also be used in the emulsions. Several examples are given.

Air or gas purification. ELEONORE RUDIL (NÉE MEIXNER). Fr. 638,313, July 27, 1927. An air or gas filter working on the turbo principle has flanges turned back to different angles to form eddies which help the deposition of dust in the angles and on the striking surfaces. The dust which is not caught in the angles tends to fall out of the filtering zone.

Purifying gases. I. G. FARBENIND. A.-G. Brit. 285,900, Nov. 26, 1926. H_2S and NH_3 are absorbed from industrial gases by washing with an aq. NH_4 sulfite-bisulfite mixt. having a ratio of SO_2 to NH_3 of 1:1.2-1.75. Washing liquors having an NH_3 content near the lower limit absorb H_2S most readily but evolve small quantities of SO_2 which must be removed from the gas by a further washing with water contg. more NH_3 . More than 2 stages may be used and the first stage may be conducted above or below the dew point. The NH_4 thiosulfate liquor produced during the process may

be converted into NH_4 sulfate and S and the S may be burned to produce SO_2 for further use in the process.

Purification of gases. SOCIÉTÉ D'ELECTROCHIMIE, D'ELECTROMÉTALLURGIE ET DES ACIÈRES ÉLECTRIQUES D'UGINE. Fr. 638,520, Dec. 6, 1926. Gases, particularly N and H for the production of NH_3 , are purified by passing them through molten Na or a molten mixt. of Na and NK.

Purification of gases. SOCIÉTÉ ANON. DES ENGRAIS ET NOIR ANIMAL. Fr. 636,162, Oct. 12, 1926. The absorbent material such as active C is placed in movable containers, e. g., on springs, which indicate by their position when the material is satd. Several containers are used in series.

Separation of gases by liquefaction. L'AIR LIQUIDE (SOC. ANON. POUR L'ÉTUDE ET L'EXPLOITATION DES PROCÉDÉS GEORGES CLAUDE). Fr. 638,382, Dec. 4, 1926. In the sepn. of gases such as H from coke oven gas or lighting gas or O and N from air by liquefaction, the gases are heated to a high temp. to decomp. any O compds. of N, or their occurrence in the gases is prevented.

Purifying liquids. CONSTRUCTION FRANÇAISE D'APPAREILS DE LAITERIE. Fr. 638,298, July 27, 1927. Liquids are passed through 2 concentric centrifuges, the inner of which travels at a much higher speed and is adapted to sep. only the larger particles, the smaller particles being sepd. in the outer one.

Clarifying liquids. ROBERT JOSEPH MARX. Fr. 636,252, June 20, 1927. The sepn. of solid particles from liquid is promoted by causing the liquid to fall in a thin film on to a hard surface to detach air bubbles prior to entry into the settling tank. The process has general application.

Extracting a liquid from easily fusible products. THE NAUGATUCK CHEMICAL COMPANY. Fr. 636,435, June 22, 1927. A liquid is extd. from easily fusible products, e. g., water is extd. from the condensation product of AcH and aniline prepd. in acid soln. by making the products fusible, e. g., with a fatty acid such as stearic acid, and heating and agitating the mixt.

Separation of solids or semi-solids from liquids. JAMES ARTHUR REAVELL. Fr. 638,255, July 26, 1927. Liquids are sprayed radially into a current of gas having a downward helical motion to sep. solids therefrom, the gas being filtered afterwards.

Separation of salts from sugar and other liquids. TROFILO GASPARY ARNAL. Fr. 636,112, June 17, 1927. The salts preventing crystn. of sugar from sugar liquids are removed by adding sol. ferrocyanides which will form insol. double ferrocyanides with the salts. Thus KCl is removed by adding $\text{Ca}_2\text{Fe}(\text{CN})_6$ or by adding CaCl_2 and $\text{Na}_4\text{Fe}(\text{CN})_6$. The invention may also be applied to other industries where it is desired to remove or modify the contents of a salt in a liquid. Thus CaCl_2 may be removed by adding $\text{K}_4\text{Fe}(\text{CN})_6$.

Clarifying turbid brines or similar liquids. ARTHUR W. ALLEN. U. S. 1,687,703, Oct. 16. A sufficiency of small crystals of a water-sol. compd. such as NaCl which is insol. in the liquor under the conditions of temp. and concn. prevailing is added to or formed in solns. or brines such as concd. natural brines to act as a mech. filter aid and the liquid is then filtered.

Refrigerating system of the absorption type. BALTZAR C. VON PLATEN and CARL G. MUNTHERS (to Electrolux Servel Corp.). U. S. 1,687,957, Oct. 16.

Refrigerating system of the absorption type. D. G. SMELLIE (to Hoover, Ltd.). Brit. 285,817, Feb. 21, 1927. An app. is described in which NH_3 or other refrigerant may be used.

Refrigerating system of the absorption type. W. B. NORMELLI. Brit. 285,798, Feb. 18, 1927. An app. working on the reversing system is described.

Evaporator for absorption refrigerating apparatus. LAWRENCE BRUEHL (to Gas Refrigeration Corp.). U. S. 1,688,377, Oct. 23.

Refrigerating apparatus of the compression type. AKT.-GES. BROWN, BOVERI ET CO. Brit. 286,229, Feb. 28, 1927.

Apparatus for vulcanizing insulation on wire with heat and pressure. LESLIE J. LAMPLUGH (to Western Electric Co.). U. S. 1,689,206, Oct. 30.

Insulators. ANDRÉ ALBERT SAMUEL. Fr. 638,525, Dec. 7, 1926. An insulating material with feeble dielec. losses at high frequency is made by the addn. to the insulating material such as "Thiolite" described in Fr. 549,811, of powd. quartz, SiO_2 , glass, mica or ebonite.

Insulated wire. EDMUND B. WHEELER (to Western Electric Co.). U. S. 1,689,311, Oct. 30. Cellulose acetate and finely divided Se are used together as a "flame-proofing" coating.

Insulating electric conductors such as wire with a single continuous layer of pre-

vulcanized hard rubber. ROBERT R. WILLIAMS (to Western Electric Co.). U. S. 1,689,312, Oct. 30. An app. is described, for hot extrusion.

Heat insulating material for safes. DAVID H. BELLAMORE and CARL P. BARTELS (to Mosler Safe Co.). U. S. 1,688,849, Oct. 23. A core of material such as diatomaceous earth embedded in heat insulating material contains moisture and is provided with a surface coating of material such as a cement compn. serving to prevent loss of moisture at ordinary temps.

Insulating plates. JOSEF WEISS. Fr. 638,422, July 29, 1927. Insulating plates are made by soaking wood fiber, straw, etc., in a lye of K_2SiO mixed with hydrous Mg silicate.

Electric insulation. A. JOFFE. Brit. 286,320, Sept. 8, 1926. A multi-layer insulating material comprises alternating layers of greater and less dielec. strength such as paper, wood, fabric or metal treated with linseed oil, resin varnishes, enamel or other suitable materials. The thickness of the better insulating layers is less than 0.01 mm. and preferably about 0.001 mm.

Flameproof electric insulation. EARL G. STURDEVANT (to Western Electric Co.). U. S. 1,687,525, Oct. 16. Insulation suitable for use on elec. conductors in strand form comprises rubber 20, chlorinated naphthalene 25, a vulcanizing agent such as S 2, a vulcanization accelerator such as PbO 10 and powdered silica, 33 parts.

Insulated electrical conductor. EDMUND B. WHEELER (to Western Electric Co.). U. S. 1,687,912, Oct. 16. A conductor such as wire is provided with a thin inner coating of baked enamel and a thin outer coating of vulcanized rubber; the enamel alone is too thin to serve as an insulation but serves to protect the conductor from the deleterious action of the ingredients of the rubber, and the rubber coating is too thin to serve alone as sufficient protection against moisture, but the 2 coatings together are highly flexible and efficient for both purposes.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Latest development in water purification. GEORGE W. FULLER. *Proc. 9th Texas Water Wks. School* 182-6(1927); *Public Health Eng. Abstracts* E-518C, 44(1928).

The newer developments in water purification have not been along the line of new processes but in the modification of the previous methods. Superchlorination and dechlorination, split chlorination and prechlorination, double coagulation, double filtration, water softening, effluent aeration, mechanically cleaned settling basin, new methods of water coagulation, boiler-feed water, new purification plants and exptl studies on filter loading are briefly discussed. Little new data are presented.

C. R. FELLERS

Water supply problems of a desert region. W. E. RUDOLPH. *Proc. Am. Soc. Civil Eng.* 54, 2287-2302(1928).—The water supply problems of the Atacama Desert of North Chile are described. Hydrological data are given for the Rio Loa and its tributaries, with descriptions of the variations in flow, evapn., seepage, salt absorption, pipe line corrosion and potability. Some cities derive their supply from melted snow while another, Tocopilla, obtains its supply by distn. of ocean water at a cost of \$0.00 per ton. Use of the waters for irrigation and hydroelec. power are discussed.

W. D. H.

Hamburg water supply. Ground water supply from Curslack. W. HOLTHUSEN. *Gas u. Wasserfach* 71, 913-24(1928).—The methods adopted for avoiding ground water contamination by seepage into wells and other details of the plant are described and illustrated.

R. W. RYAN

Water supply of Los Angeles. WM. MULHOLLAND. *J. Am. Water Works Assoc.* 20, 463-6(1928).—The Owens Valley supply not being sufficient in view of the rapid growth of the city, plans are now under way to go to the Colorado River and only await approval of the Boulder Dam project.

D. K. FRENCH

Investigation of the impurities in the water of the Kiel Inlet. KARL KISSKALT. *Arch. Hyg.* 99, 99-110(1928).—Analyses are given of water taken from various parts of the harbor.

P. Y. JACKSON

Results of the investigation of the impurities in the water of Kiel Inlet in the years 1926-27. W. LIESE. *Arch. Hyg.* 99, 111-7(1928).—Cf. preceding abstr. P. Y. J.

Manganese in the water supplies of the Rhine province. KARL KISSKALT. *Arch. Hyg.* 99, 96-8(1928).—In 2 regions of the lower Rhine province Mn has been found in appreciable quantities in drinking water.

P. Y. JACKSON

Eliminating tastes and odors by algae in water. CHESTER COHEN. *The American City* 38, No. 4, 129-30(1928); *Public Health Eng. Abstracts* E-518C, 42(1928).—Algae in southern states where climatic conditions are favorable to their growth are partly responsible for discoloring the water, for imparting tastes and odors to the water and for clogging filter beds and filling the pores of the filter material. Their presence is also quite common in swimming pools. Living algae produce oils which give the water a fishy, oily or grassy taste. When the food supply becomes exhausted or if destroyed by chem. treatment, decompn. occurs, producing a strong medicinal taste when Cl is used for purification. Algae may be controlled by covering the reservoir to cut off sunlight or by treatment of the water with CuSO_4 or Cl. The dosage of either required must be detd. according to the type of algae growth. Water weeds in large reservoirs are usually destroyed by cutting the tops below the water line or by pulling the weeds.

C. R. FELLERS

Chlorophenol tastes from creosoted wood stave pipe. DANA E. KEPNER. *J. Am. Water Works Asscn.* 20, 473-8(1928).—Several cases are cited to show that the characteristic chlorophenol taste is developed when chlorinated water comes in contact with relatively new creosoted wood pipe.

D. K. FRENCH

Water hardness, its effects and its removal. RUDOLPH E. THOMPSON. *J. Am. Water Works Asscn.* 20, 479-80(1928); cf. *C. A.* 22, 1639.—A summary of various methods of water softening.

D. K. FRENCH

The chlorine number and chlorine requirement of water. The estimation of ability to combine with chlorine. HANS WETTE. *Arch. Hyg.* 99, 143-57(1928).—Since some decompn. products of proteins are not oxidized by the usual method of Kubel-Tiemann, the values so detd. may fail to show some impurities of hygienic importance. The Cl no. is of value in such cases. Since some Cl is taken up by org. material and can then no longer exert its bactericidal properties the amt. so removed by combination must apparently be detd. in order that just sufficient excess may be present to sterilize the water. However, when a single drop of Cl water (contg. 0.01 mg. Cl_2) was added to distd. water, cond. water, or to urea solns. of varying concn., no test for Cl could be obtained with the benzidine test after 5 min. A second drop of Cl water gave a pos. test for all solns. This test is not sufficient to det. the amt. of extra Cl required by the urea in the soln. NaHCO_3 in soln. unites with Cl, and the amt. so taken up is not affected by the presence of dissolved urea.

P. Y. JACKSON

Chlorinated copperas—a new coagulant. L. L. HEDGPETH, N. C. OLSEN AND WM. C. OLSEN. *J. Am. Water Works Asscn.* 20, 467-72(1928).— FeSO_4 was found unsatisfactory as a coagulant. When oxidized with Cl water, 1 pt. Cl to 7.8 pts. FeSO_4 , it was most effective. It is followed by alum and lime or Na aluminate. Two applications are essential, the first between pH 4.2 and 4.7, the second between pH 5.5 and 6.5.

D. K. FRENCH

Electrolytic corrosion prevention of condenser tube corrosives. F. G. PHILO. *J. Am. Water Works Asscn.* 20, 505-34(1928).—Conditions at the Long Beach plant of the Southern California Edison Co. are described. The electrolytic protective system consists of 16 cast-iron anodes properly placed and insulated. The article is very complete and detailed. The cost is low and the results are considered satisfactory.

D. K. FRENCH

Succinchlorimide for the treatment of small quantities of potable water. CYRUS B. WOOD. *J. Am. Water Works Asscn.* 20, 535-49; *Military Surgeon* 63, 493-506(1928).—This compd. can be prepd. in many ways, which are described. It is very sol. and stable. It imparts a slight saline taste to water. In water it liberates HOCl . It is considered satisfactory in sterilizing small quantities of water down to the capacity of the soldier's canteen.

D. K. FRENCH

British and American practice in rapid sand filtration. S. W. FARRINGTON. *Munic. Eng. Sanit. Record* 81, 546-7(1928); cf. *C. A.* 22, 4683.—T. discusses the different practices in automatic control of chem. feeding in accordance with water flow, the times of reaction and flocculation, and the washing of filters. In Cork there is no quiescent subsidence period. The influent to the filters therefore contains no floc but a finely divided ppt. There are no troughs used for washing the sand filters, but instead a low weir at the end of the bed a few in. above the sand is used. Consequently the vertical velocity is at a min.: 6.25 gal. per sq. ft. per min.

C. H. BADGER

Ground water carriers of the lower Elbe region. E. KOCH. *Mineral. Geol. Staat. inst. Hamburg. Gas u. Wasserfach* 71, 889-95(1928).—The geological structure of the water-bearing strata of the Hamburg region is illustrated and discussed.

R. W. RYAN

River pollution. C. C. DUNCAN. *Munic. Eng. Sanit. Record* 81, 501-2(1928).—

The river Severn is on the whole not seriously polluted. It is often turbid which necessitates frequent cleaning of the filters. After purification, it supplies the towns of Worcester and Tewkesbury. The river Stour, contaminated by a sugar factory, and the Salwarpe, a small stream too salty because of springs, are not used for water supplies.

C. H. BADGER

The sewage disposal works of Decatur, Illinois. S. A. GREERLEY AND W. D. HATFIELD. *Proc. Am. Soc. Civil Eng.* **54**, 2237-86(1928).—Since 1917 the Sanitary District of Decatur, Ill., has completed intercepting sewers, pumping station and sewage treatment works including grit chambers, Imhoff tanks, digestion gas collectors, odor burning oven, sludge drying beds, preaeration units, sprinkling filters and secondary settling tanks at a total construction cost of \$1,700,000. The treatment of the sewage has been complicated by wastes from a large corn products factory which have had a population equiv. to 300,000, but which have been reduced to 225,000 and are expected to be reduced to less than 100,000 in the near future. Two testing stations have been operated in connection with the design and construction of the plant. The engineering and chem. data on design, construction, operation and aeration testing station are quite complete.

W. D. H.

The oxidation of sulfur in suspensions of activated sludge and its influence on the solubilization of mineral phosphates. C. V. RAMASWAMI AYYAR, T. S. S. PERUMAL AND ROLAND V. NORRIS. Dept. Biochem. Indian Inst. Sci., Bangalore. *J. Indian Inst. Sci.* **11A**, pt. 8, 85-90(1928).—In an attempt economically to utilize the large natural deposits of rock phosphate in India by treatment with activated sludge suspensions, preliminary lab. and field expts. were carried out. The rock used contained 44 and 26% of insol. P_2O_5 , resp. With the rapid oxidation of elemental S there was an accumulation of H_2O -sol. sulfate. Generally the amt. of S oxidized in relation to the H_2O -sol. phosphate produced was in the ratio of 4 of S to 1 of mineral phosphate. The introduction of catalysts reduced the ratio to 1:1. In the S series without a neutralization agent the pH fell to 1.6 and there was a rapid production of titratable acidity. When phosphate was added, although there was a greater production of acid, this was utilized for the production of sol. phosphate, the pH remaining at about 4.6. In the absence of catalysts ($MnSO_4$, $Al_2(SO_4)_3$ or $FeSO_4$), even though there was increased S oxidation as indicated by the sulfate figures, there was not a corresponding increase in the production of H_2O -sol. phosphate; but with $MnSO_4$ or $Al_2(SO_4)_3$, the soly. rapidly increased.

C. R. FRILLERS

The Worcester (England) activated sludge plant. THOMAS CAINK. *Munic. Eng. Sanit. Record* **81**, 502(1928).—C. ests. £15,000 as the cost of covering 2 acres of land to air-dry sludge from an activated sludge plant, a small part of £750,000 estd. as cost of sewage works for 50,000 population.

C. H. BADGER

Municipal administration at Thornaby-on-Tees (England). G. H. CONNOR. *Munic. Eng. Sanit. Record* **81**, 490(1928).—C. gives brief statements regarding high ways, sewerage and sewage disposal, public lighting and refuse disposal. Sewage gravitates to the tidal waters of the river Tees without any treatment.

C. H. B.

Some municipal works at Totnes (England). JOHN L. DAVIES. *Munic. Eng. Sanit. Record* **81**, 517(1928).—Brief statements are made regarding highways, sewerage system, disposal of house refuse, water supply and public lighting.

C. H. B.

Health in industry. C. L. FERGUSON. *J. Am. Med. Assoc.* **91**, 868-70(1928).—A general survey.

L. W. RIGGS

Recent municipal work in Stafford (England). W. PLANT. *Munic. Eng. Sanit. Record* **81**, 462-3(1928).—The water supply is pumped from a well and bore hole. An inadequate storage reservoir of 577,000 gal. will be replaced by a million gal. concrete storage reservoir (2-day normal supply). Every house is provided with duplicate drains. The surface water finally discharges into stream courses. The sewage gravitates to a reception tank, passes through mech. coarse screens, is pumped to the disposal works, where it is treated by chemicals and settled in a pptn. tank. The tank effluent is distributed over 50 acres of land, underdrained at 6 ft. depth, the subsoil being sand and gravel. Since a stable effluent cannot always be obtained because of the small land area, 6 activated sludge units will be built. A unit, now completed, has produced a stable effluent with spent liquor from a $(NH_4)_2SO_4$ plant of a gas works. Sewage with abnormal Cl content, due to salt works, is amenable to this treatment. House refuse is burnt to provide steam at the sewage disposal plant. A description of the roads and baths is also given.

C. H. BADGER

Cleansing activities in Blackburn (England). J. RECLESTON. *Munic. Eng. Sanit. Record* **81**, 470-1(1928).—House refuse is chiefly collected by light wt. carts. It is now screened by a $1/2$ in. mesh rotary screen. Dust averages 35% of the refuse.

and is hauled away. The screenings are sorted for saleable articles and the remainder together with cinders burnt for steam purposes. Formerly burning the unscreened refuse caused troublesome dust emission in the thickly populated neighborhood.

C. H. BADGER

The treatment of organic wastes. W. WEAVER. *Surveyor* 74, 83(1928).—Slaughter house, fish market and vegetable wastes are treated by the Iwel dry-rendering process. Dried vegetable matter on analysis gave NH_3 3, phosphates 4, K_2SO_4 2.6, org. matter 60 and mineral matter 13%. Combined vegetable and foreign matter averaged on analysis: NH_3 1.5, phosphates 2.5, K_2SO_4 1.8 and org. matter 75%. The use of these materials as fertilizers was considered.

A. L. ELDER

Fumigation with cyanogen products. C. V. AKIN AND G. C. SHERRARD. U. S. Public Health Service. *Public Health Reports* 43, 2847-70(1928).—This paper is a report of expts. conducted with cyanogen products used in the fumigation of vessels for quarantine purposes at the New York Quarantine Station. The products carried were (1) liquid HCN 96 to 98%, (2) a mixt. of 80% liquid HCN and 20% CNCl , (3) HCN generated from mixts. of NaCN , NaClO_3 and HCl or NaCN , H_2SO_4 66 Bé. and H_2O , (4) Zyklon-B, a product of German manuf. contg. liquid HCN and 4 to 10% of chloropicrin, (5) $\text{Ca}(\text{CN})_2 \cdot 2\text{HCN}$ in the form of a fine dust which evolved HCN in the presence of even traces of moisture. Two adjoining rooms of equal size in a vacant building were prepd. by covering the floors, ceilings and sides with cement mortar, and were painted to prevent leakage. The partition wall between the rooms carried a no. of 2-in. holes at different heights to test gas circulation. These holes could be opened or stoppered gas-tight at will. Two or more adult white rats were used in all of the more delicate tests. The following are some of the results: (1) Within a single nearly air-tight room and in the absence of air currents HCN or $\text{HCN} + \text{tear gas}$ tend to rise. Rats in cages near the ceiling were killed before those on the floor when the 2 lots of animals were equally distant from the source of gas generation. With one room contg. 2 oz. of HCN per 1000 cu. ft. and 2 or 3 2-in. holes open in the partition wall, the HCN showed little tendency to pass to the other room regardless of temp. changes or the operation of an elec. fan in either room. In ridding ships of rats by means of HCN , the complete opening up or elimination of dead spaces is of equal importance to gas dosage, exposure time or fumigant used. (2) HCN was found in dangerous concn. in the residues after fumigation by the $\text{NaCN} + \text{acid}$ and the $\text{Ca}(\text{CN})_2 \cdot 2\text{HCN} + \text{H}_2\text{O}$ reactions, and in much smaller quantities in the residues of Zyklon-B. (3) Residues of $\text{Ca}(\text{CN})_2$ absorb lethal amts. of HCN ; those from Zyklon-B absorb much less. (4) Brief exposures to HCN of high concn. is more uniformly fatal than prolonged exposure to doses approaching the threshold concn. (5) Moisture, even that in materials dry to touch, will take up lethal quantities of HCN and hold it longer than perfectly dry materials. (6) Bedding, clothing and floor coverings should be removed from rooms during fumigation. This is particularly necessary in the crew's quarters. Rats were protected from the standard dose of HCN by 80 layers of dry gunny sacks, 40 layers of wet gunny sacks or 16 to 20 layers of blankets. (7) Mixts. of HCN and tear gas are used with the idea that the absence of tear gas after fumigation indicates the absence of HCN . This test is unsafe. The presence or absence of HCN should be detd. by test animals. In comparative applicability, usefulness, public safety and cost, Zyklon-B is superior to the other methods of producing HCN for fumigating purposes. It is practical for use in small units as well as large.

L. W. RIGGS

H-ion control of boiler feed waters (ANON.) 28. The purification and disposal of waste waters (ROSS, DE FROBERVILLE) 28.

Filter for water, etc. BENJAMIN J. PIERSON (to D. H. P. Mfg. Co.). U. S. 1,688,152, Oct. 16.

Sterilizing water. O. ADLER and R. ADLER. Brit. 286,338, Nov. 4, 1926. Water which has been sterilized by treatment with free Cl , hypochlorite or "chloride of lime" is passed through or over coarse pieces of carbonaceous material, to convert the excess Cl into HCl or chloride. To secure more effective sterilization, the water, before contact with the carbon, may be passed through clay, sand, quartz powder, glass powder, asbestos, spun glass, kieselguhr or other porous material unaffected by Cl or Cl compds. HCl in the treated water may be neutralized with limestone.

Meter and flow-control device for proportionate feeding of chlorine to water, etc. PAUL LANHAM. U. S. 1,689,491, Oct. 30.

Softening water. PAUL E. LEISS. U. S. 1,689,036, Oct. 23. BaCO_3 and Ca(OH)_2 are preliminarily mixed with water and the mixt. is added to water to be softened.

Apparatus for softening water. J. MILLS & Co. (ENGINEERS), LTD. AND W. H. PORTER. Brit. 285,629, Jan. 20, 1927. Water to be softened passes through an injector device which draws NaOH soln. from a boiler and the water then passes through a specially constructed settling and filtering app. Cf. C. A. 22, 3941.

Apparatus for softening water by treatment with zeolites. JOSEPH J. TOMKINSON. U. S. 1,688,366, Oct. 23.

Softening and purifying water. A. ROSENHEIM. Brit. 286,307, March 4, 1927. In order to soften it and remove Fe and Mn, water is treated with a gel of an acid or amphoteric substance such as silicic acid, titanin acid, alumina, chromic oxide or ferrous or ferric oxide, in the presence of basic substances such as alkalis, alkali carbonates, lime, baryta or strontia or alk. reacting salts such as borates, phosphates, cyanides, silicates, aluminates, stannates, titanates or the like. AlCl_3 or FeCl_3 may be added to the sol and a mixed gel pptd. with alkali.

Apparatus for softening water with base-exchange material. JOHN ASTROM (one-half to Deister Machine Co.). U. S. 1,688,915, Oct. 23.

Tank and connections, etc., for use in softening water with zeolites. CHARLES A. STICKNEY (to Stickney Hydraulic Co.). U. S. 1,689,308, Oct. 30.

Apparatus for treating sea water with reagent solutions to precipitate salts. R. J. WOOD. Brit. 285,954, Nov. 19, 1926.

Two-stage activated-sludge process of treating sewage. ACTIVATED SEWAGE, LTD. AND J. A. COOMBS. Brit. 285,944, Oct. 27, 1926. Each of 2 stages of treatment comprises addn. of sludge and aeration and the sludge used for the different stages is separately revived. The first stage leads to the sepn. of carbonaceous material and the second to the conversion of the NH_3 compds. present into nitrites and nitrates by the action of bacteria cultivated in sludge which has not been in contact with sewage contg. large quantities of carbonaceous material. An app. and numerous details of procedure are described.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Soil surveys. F. S. EARLE. *Facts about Sugar* 23, 978(1928).—E. questions Arrhenius' and Willcox's apparent rejection of the idea of "soil type" and believes that the term may be defined so as to be of great agricultural value if based upon "natural" characteristics. A single character such as particle size (as in Bennett and Allison's work (C. A. 22, 2804)) or soil reaction (as in Arrhenius' work, (C. A. 21, 1830, 2569, 3411)) is inadequate as a basis of classification. The geological origin and natural vegetation are factors of prime importance. In Cuba at least, permeability is also important because permeable soils respond to treatment with chem. fertilizers and impermeable ones do not. Lines representing soil reaction and nitrifying power will not be found crossing indiscriminately the areas of definite soil types in Cuba. The degree of acidity is not a dependable index of the need of phosphates; the older "red lands" of Cuba are notably deficient in phosphates and only slightly acid. The question of cane varieties cannot be ignored in pH surveys. Comparing the sugar yields of different varieties grown on acid soils with the yields of the same varieties grown on alk. soils, Alfaro finds that *Uba* gives consistently lower yields on acid soils, while *Cristalina* usually gives as good or better yields on moderately acid soils. E. has observed that *Co. 213* and other *Saccharum barberi* hybrids endure strongly alk. soils better than *Cristalina* and much better than *Badila*. Reply. O. W. WILLCOX. *Ibid* 978-9.—W. disclaims any doubt that soil types are real, but he believes that lines representing soil reaction will be found to cross them. Not enough work has been done in Cuba to prove that Arrhenius' method is not as applicable there as elsewhere. A.'s work in Europe and Java has been carried out on a scale wholly without precedent and yields have been correlated with soil reaction in vast numbers of fields. This is the distinctive feature of A.'s method. E.'s suggestion that cane varieties differ in their preferences as to soil reaction is important.

M. J. PROFFITT

New colorimetric determination of the phosphoric acid requirement of soils. ANTONÍN NĚMEC. Staatlichen Versuchsanstalten für Pflanzenproduktion, Prag *Biochem. Z.* 198, 112-27(1928); cf. C. A. 22, 2427.—It appears probable, on the basis of further exact field investigations, to set up definite limits of the silicic acid content of soils, which det. beforehand the plausible phosphoric acid action of the fertilizer for

different plants, on the basis of a quick colorimetric silicic acid-phosphoric acid detn. in soil exts. The mutual relationship of the phosphoric acid and silicic acid compds. of soil in plant nutrition deserve therefore a further exhaustive study, especially from the physiol. standpoint. The investigations show in general, that also the hitherto neglected, useful elements fulfill their important role in plant biochemistry, at least in combination with the nutritive substances which today are regarded as the principal ones.

E. F. SNYDER

Measuring the acidity (p_H) of soils by the inversion of sucrose. V. VINCENT. Station Agronomique du Finistère. *Chimie et industrie* Special No., 843-8 (April, 1928); cf. *C. A.* 21, 1580.—The results are given in detail of an investigation on the possibility of detg. the p_H value of soils by sucrose inversion, from which, contrary to Parker and Bryan (*C. A.* 17, 3068), V. concludes that the method is incapable of giving reliable results. It was found that soils having practically the same initial p_H value but different chem. compn. inverted sugar differently and that soils that were almost neutral had an appreciable inverting action; moreover the p_H value calcd. from sucrose inversion is lower than that obtained by direct detn., and is lower at high than at low temp., irrespective of whether the soil is acid, neutral or alk. Study of the action of heat on various buffers indicated that the results obtained with soils are due to the phosphate buffers which they contain, the degree of hydrolysis being increased on raising the temp. and reduced on lowering it, but not always to its original value.

A. PAPINEAU-COUTURE

Asbestos waste: An inquiry as to its value for the correction of soil acidity. FRANK T. SHUTT. *Dept. Agr. Canada, Rept. Dominion Chemist, Year Ending March 31, 1927, 1928*, 13-6.—Asbestos waste is essentially hydrated Mg silicate from which the fibrous asbestos has been removed as far as possible by milling processes. Expts. with this material, ground to a fairly fine powder, showed that it has no value for reducing the lime requirement and the p_H of acid soils.

K. D. JACOB

The lime requirements of acid soils. CH. BRIOUX. Station agronomique de la Seine-Inférieure. *Chimie et industrie* Special No., 899-903 (April, 1928); cf. *C. A.* 22, 1004.—A comparison of the p_H value and CaO requirements of a no. of soils detd. by both the Hutchinson-MacLennan method (shaking 15 g. of soil with 300 cc. 0.02 N $\text{CaH}_2(\text{CO}_3)_2$ and detg. CaO in the soln. before and after) and the electrometric method (plotting p_H values against increasing amts. of lime water) showed that the 2 methods give results of the same order (generally within 0.01-0.02%) except with soils having a high humus content, in which case the Hutchinson-McLennan method gives results up to 50% lower than the electrometric. The initial p_H value of itself gives no indication of the CaO requirements. B. suggests expressing the CaO requirements by means of the "saln. no." of the soil, which he defines as the no. of mg. of CaO required per kg. of soil to increase the p_H by 0.1. It is generally considered that in practice the amt. of CaO found by lab. tests should be increased by about 50%. B. found that even on adding up to thrice the theoretical CaO requirement the p_H of the soil gradually decreased to slightly less than 7.0 in a few months; while if exactly the theoretical amt. was added the p_H might even fall below its original value. Nitric N detns. showed that in no case could nitrification account for the neutralization of the whole of the CaO. The mechanism of the re-acidification has not been elucidated, but B. suggests it may be due to the presence of certain unneutralized silicates having an extremely low soly., the acid radicals of which do not act appreciably at the original p_H values of the soils, but which are very slowly neutralized by the added CaO. There may also be formed org. acid compds. by oxidation of the humus.

A. P.-C.

The purchase of agricultural lime. LENGLEN AND DURIER. *Chimie et industrie* Special No., 880-3 (April, 1928).—A plea for the sale of agricultural lime on the basis of available CaO content, showing the serious disadvantages of the present system of sale without control of the CaO content.

A. PAPINEAU-COUTURE

The chemical effect of gypsum, sulfur, iron sulfate, and alum on alkali soil. W. P. KELLY AND ALEXANDER ARANY. Univ. of Calif. *Hilgardia* 3, 393-420 (1928).—The application of gypsum, S, FeSO_4 , and alum produced important chem. changes in black-alkali soil near Fresno, California. With each of these materials the chem. reactions involved the sol. carbonate and the exchange complex of the soil. Gypsum pptd. the sol. carbonate as CaCO_3 while the other materials either decompd. carbonate or else converted it into bicarbonate. Simultaneously with the effect on sol. carbonate, the exchange complex has been acted upon. The effect of gypsum is dependent on its sol. Ca, while S, FeSO_4 , and alum are effective because of the H ions that are formed. The acid formed by the oxidation of S, or the hydrolysis of FeSO_4 and alum, dissolves CaCO_3 , and possibly other minerals, and thus brings Ca into soln. As a result the Na

content of the exchange complex is decreased and the Ca content is increased. Resulting from these chem. transformations the phys. conditions of the soil have been markedly improved and the growth of crops was stimulated. The theoretical and practical aspects of the black-alkali soil problem is discussed. J. J. SKINNER

The microorganisms of cultivated and bush soils in Victoria. DOROTHY DIXON. Melbourne Univ. *Australian J. Exptl. Biol. Med. Sci.* **5**, [3], 223-32(1928).—When the mean nos. of fungi and actinomycetes are plotted from month to month the curves follow the rainfall more or less closely. The temp. exerts a slight influence in the coldest month by hindering growth and reproduction. The max. counts in the majority of cases occurred in the early autumn and early spring months. The difference between the curves for the organisms present in orchard soil as compared with bush soil can be ascribed to the soil structural differences. The balance between the types of organisms in the soils appears to change from month to month. The genera isolated appear to be the same as those found in northern regions. Types such as the *Mucors* seem to show fluctuations in their nos. during the year. L. W. RIGGS

Technical control of small farms. JACQUES DE VILMORIN. *Chimie et industrie Special No.*, 912-3(April, 1928).—A brief discussion of the advantages of carrying out simple control tests on small farms. A. PAPINEAU-COUTURE

Mixed and complete fertilizers. A. MITTASCH. *Z. angew. Chem.* **41**, 902-16(1928).—A discussion of the chem., technical and agricultural side of mixed and complete fertilizers. E. F. SNYDER

The manufacture of fertilizers and its relation to the agriculture of Hawaii. C. G. OWEN. *Facts about Sugar* **23**, 975-6(1928).—Fertilizers should be selected with respect to their ability to stimulate plant growth, their cost, their mech. suitability and the adequacy of their supply. The newer types of fertilizer are more coned. than the old. A table of typical analyses is given. M. J. PROFFITT

Determination of nitrogen in artificial fertilizers. E. THOREL. *Chimie et industrie Special No.*, 887-9(April, 1928).—See C. A. **22**, 3947. A. PAPINEAU-COUTURE

The present status of the nitrogen problem. J. GALLAND. *Chimie et industrie Special No.*, 872-8(April, 1928).—A review of the status of the effects of N from an agronomic standpoint. A. PAPINEAU-COUTURE

A new aspect of the agricultural nitrogen problem. E. BURBAN. *Chimie et industrie Special No.*, 898(April, 1928).—A plea for the utilization of weak HNO_3 (30° Bé.) directly as it comes from the absorption towers of synthetic HNO_3 plants for the production of fertilizers such as nitrophosphates (obtained by action of HNO_3 on natural phosphates) which could be carried out directly in the field. A. PAPINEAU-COUTURE

Influence of certain fertilizers and chemical agents on the weight of the crop and the alkaloidal content in the culture of the lupine legume. ALBERT GUILLAUME. *Bull. sci. pharmacol.* **35**, 347-53, 495-9(1928).—The plant, *Lupinus mutabilis* var. Cruiskanks, was grown in poor soil as control, also in the same soil to which was added fertilizers as follows: (a) complete fertilizer consisting of $(\text{NH}_4)_2\text{HPO}_4$, K_2SO_4 , FeSO_4 , MnSO_4 , MgCO_3 and colloidal MgSiO_3 ; (b) this complete fertilizer without the MgCO_3 ; (c) each constituent of the complete fertilizer singly, also KCl , NH_4NO_3 and $(\text{NH}_4)_2\text{SO}_4$ singly. In every case there was an increased yield of entire plant over the control. MgCO_3 at the rate of 20 g. per sq. m. produced the largest yield of plant tissue of any fertilizer taken singly, but caused no increase in the alkaloidal content. Both KCl and K_2SO_4 caused abs. and relative decreases in the alkaloidal content. The largest increase in alkaloidal content followed the use of a complete fertilizer. Under the action of CO_2 , addnl. to that of the atm., there was an increase in the yield of plant tissue but not in the alkaloidal content. L. W. RIGGS

Fertilization of the soils of the Landes of Gascony. RENÉ MARCARD. *Chimie et industrie Special No.*, 868-71(April, 1928).—These soils have a very poor phys. and chem. constitution, consisting of about 93-4% SiO_2 and having very poor H_2O -retaining properties. Large applications of fertilizers are of very little value, as they are rapidly washed away; but satisfactory results can be obtained to some extent by repeated application of small quantities of fertilizers at the times when they are most needed by the plants. A. PAPINEAU-COUTURE

Results obtained from collective field experiments with fertilizers in Tula district. A. V. KAZAKOV. *Trans. Sci. Inst. Fertilizers (Moscow)* No. **35**, 9-42(1928).—K. summarizes the results of fertilizer expts. carried out in the district of Tula on the podzolized loams, sandy loam, gray forest soils, dark forest soils, degraded and leached chernozem for the period of 1903 to 1925. With rye, the podzolized loams responded to the treatment of phosphates from Thomas slag, superphosphate and bone meal equally well. These soils also responded to K treatment. The gray forest soils re-

sponded to the fertilizer treatment in the same way as the podzolized soils. Stable manure has proven to be more effective than phosphates on the soils mentioned. The dark forest soils responded primarily to phosphates, this element thus being the minimum factor in this soil. Rock phosphate was just as effective as Thomas slag or bone meal. On degraded chernozem, phosphates and manure gave the best results. There was no response to N and K. The same was true for leached chernozem. The oats did not respond as well as the rye to phosphate applications on either of the soils. On the other hand, oats responded better than rye to N fertilization. With potatoes the data were meager, but there is indication that N and K are the limiting factors on the soils mentioned. The results of expts. on spring wheat, fodder beets, winter wheat, barley and flax did not warrant any definite conclusions. Clover responded to superphosphate and K. The other hay grasses did not show any striking differences due to fertilizers. The hay fields which became flooded responded to phosphate and K fertilizers.

J. S. JOFFE

Fertilizer experiments in the Tver district. A. V. KAZAKOV AND S. L. SHAPIRO. *Trans. Sci. Inst. Fertilizers* (Moscow) No. 37, 61-91(1926).—The sandy and loam soils respond primarily to P; without it N and K have no effect. For grain Thomas slag was just as good as acid phosphate; clover responded best to acid phosphate. Additions of iron sulfate gave a very slight increase. The experiments were conducted with rye, wheat, barley, potatoes, clover, meadow hay and flax.

J. S. JOFFE

Fertilizer experiments in the Vladimir district. L. L. BALASHEV. *Trans. Sci. Inst. Fertilizers* (Moscow) No. 37, 5-60(1926).—Loam soils respond best to P while light soils respond to N and N-K fertilizers. A complete fertilizer is effective on rye and oats in sandy soils and on flax in loam soil. Barnyard manure (1000-1500 poods per desiatin) on light soils was more effective than com. fertilizers. Phosphates are very effective on crops following grasses or sod. K_2SO_4 was more effective on clover than any other K salt; the reverse was true for potatoes and flax. Addns. of Mn in the form of the oxides gave neg. results. The starch content of potatoes was lowered because of the K fertilizers, especially with the KCl; no such diminution was caused by the P fertilizers.

J. S. JOFFE

Experiments with fertilizers in Moscow district. L. L. BALASHEV. *Trans. Sci. Inst. Fertilizers* (Moscow) No. 35, 83-153(1926).—The numerous expts. conducted with the effect of fertilizers on various crops are summarized as follows: grain crops respond to the 3 important fertilizer ingredients in the following order: $N > P > K$. Whenever a grain crop is introduced in the rotation P comes as the first minimum. With potatoes, flax and clover the order of the effects of the fertilizer ingredients is: $K > P > N$. Meadow hay responds primarily to K. Liming of soils increased the yield of clover and grain crop. NaCl was effective on flax.

J. S. JOFFE

Summary of fertilizer experiments by the agricultural experiment stations of Tula district. A. V. KAZAKOV. *Trans. Sci. Inst. Fertilizers* (Moscow) No. 35, 43-83 (1926).—On the northern degraded chernozem P is in the first minimum. Ground rock phosphate, bone meal, Thomas slag and superphosphate were equally effective on rye, although the ratio of quantities applied had to be: 6:4:4:3 for the resp. sources of P. N and K had no effect. Winter wheat responded even better than rye to P applications, irrespective of the source of the P. No response was obtained with N or K. Oats behaved in the same way as rye and wheat, although the effect of the P was less marked. Hemp and flax were very sensitive to P applications. The legumes responded to P and showed decreased yields (especially lupines) with N fertilizers. Similar results on the effects of soil phosphates were obtained on the gray podzolized and slightly podzolized loams.

J. S. JOFFE

Measuring the assimilability of various phosphates by means of their action on the bacterial fixation of nitrogen. GEORGES TRUFFAUT. *Chimie et industrie Special No.*, 890-4(April, 1928); cf. C. A. 21, 943.—The method of Stoklas and Waksman (C. A. 19, 3342) has been improved as follows: (1) the glucose medium is inoculated not only with *Azotobacter*, but with 4 different N-fixing bacteria, *Clostridium pastorianum*, *B. triffauti*, *A. chroococcum* and *A. agile*; (2) the culture medium contains no source of P other than that in the sample examd., and to this end H_2O redistd. over $KMnO_4$ is used in its prepn.; (3) a uniform phosphoric acid content of 0.4 g. per l. is used; (4) addn. of 2 mg. N per l. (in the form of egg albumin) practically eliminates differences which might take place in the rate at which development of the cultures sets in with the different phosphates. The technic of the method is described. The expts. on the effects of the presence of F on the assimilability of various phosphates are described (cf. C. A. 21, 2953). In the presence of excess $CaCO_3$, Gafsa phosphate and phosphated chalk cause very slight fixation of N, neutral phosphate (natural phosphate

treated with the theoretical amt. of H_2SO_4 to decomp. fluophosphates and combine with Al_2O_3 and Fe_2O_3) was the most efficient, closely followed by superphosphate, and basic slag showed the same activity as $CaHPO_4$ and $Ca_3(PO_4)_2$. Optimum N fixation is obtained only with the combination of the 4 organisms and cannot be obtained with *Azotobacter* alone. The presence of 2 mg. N per l. very greatly increases the N fixation. The p_H value greatly influences N fixation: in absence of $CaCO_3$, superphosphate (p_H 1.4) causes no fixation of N, and neutral phosphate (p_H 3.1) very little, while Moroccan phosphate (which contains $CaCO_3$) causes some fixation; subsequent addn. of $CaCO_3$ increases N fixation, but not to the same pt. as when the medium originally contained $CaCO_3$. A. PAPINEAU-COUTURE

The pretended acidity of superphosphates. M. DURIER AND M. LENGLEN. *Chimie et industrie Special No.*, 879 (April, 1928).—Examn. of 21 samples of com. superphosphates made in different plants and contg. 13–7% of citrate-sol. P_2O_5 showed that 7 contained not even a trace of H_2SO_4 and the others all contained less than 0.024%. The free H_3PO_4 content was 1–5.56%. A. PAPINEAU-COUTURE

Phosphoric acid and lime (in agriculture). E. BURBAN. *Chimie et industrie Special No.*, 897 (April, 1928).—In the soil, the acidity of superphosphate is neutralized: in the presence of $CaCO_3$ it forms insol. $Ca_3(PO_4)_2$ in a fine state of subdivision, which can be rapidly assimilated by the plants; in the absence of $CaCO_3$ it gives insol. Fe and Al phosphates which can also be assimilated, but only much more slowly. When added to soils which are poor, but not entirely deficient, in $CaCO_3$, CaO by combining with superphosphate helps to prevent further decalcification and indirect acidification. A. PAPINEAU-COUTURE

Importance of adsorption phenomena in agronomy. G. BARBIER. *Chimie et industrie Special No.*, 895–6 (April, 1928).—A brief discussion of the practical consequences of the law of adsorption $y = kx^{1/p}$. A. PAPINEAU-COUTURE

The toxicity of certain fertilizing materials and their utilization in agriculture. A. BRUNO. *Chimie et industrie Special No.*, 909–11 (April, 1928).—A brief discussion of the possibility of utilizing products such as crude ammonia, cyanamide, borax-contg. potash, etc., in such a manner as to utilize their toxic properties for cleaning the ground and their fertilizing properties for increasing the crops. A. PAPINEAU-COUTURE

Three years' experience on the fertilization of wheat lands. LENGLEN. *Chimie et industrie Special No.*, 884–6 (April, 1928).—Results of field tests carried out in 1922–26 showed that with increase in the amt. of fertilizer the yield of grain and straw increases to a max., which is reached with 55–70 kg. of N per ha., whereas it was heretofore considered that the max. amt. used should be about 35 kg. The fertilizer is utilized to the best advantage in fertile and well-cultivated soils. A. PAPINEAU-COUTURE

Field problems on an unirrigated plantation. A. T. SPALDING. *Facts about Sugar* 23, 1025 (1928).—The cost of material and labor for fertilization and the cost of weeding and cultivation, which is almost wholly labor expense, are the principal costs of growing cane in Hawaii. On 5 plantations in the Hilo district, the av. cost of weeding and cultivation was 36.78% of the total cost of bringing the crop of cane to maturity. An investment in research on the problem would seem to be amply justified. M. J. PROFFITT

Loss of valuable plant foods through the ground water. M. GERLACH. *Z. Ver deut. Zuckerind.* No. 863, 175–86 (1928).—A description of the lysimeters at the Kaiser-Wilhelm-Inst. is given. The quantity of ground water is influenced by (1) The porosity of the soil; its fertilization. Fertilized fields lost 15–137% of the precipitation; unfertilized 24–41%. (2) The till of the soil, fallow fields losing more ground water than planted fields. (3) The type of precipitation. (4) Temp. A discussion of the residual effect of various manures is given. The plant food balance for 11 years of the lysimeter expts. is given, showing large losses of N and K and a small loss of $CaCO_3$ in spite of fertilization and liming. Phosphate losses were overcome by fertilizing. E. A. FINGER

Calcium carbonate as a factor in the distribution of plants in Finland. V. A. PESOLA. *Ann. Soc. Zoolog.-Bot. Fenn. Vanamo* 9, No. 1, 2466 pp. (1928).—Finnish with English summary. About 900 plant assocns. in both high and low lime areas were studied, the presence of $CaCO_3$ in the rocks being detd. by HCl or by using certain lime-loving mosses as indicators. The plants prove divisible into: obligate calciphiles, always on high-lime soils; calciphiles, often on high, sometimes on low; subcalciphiles, often on low, sometimes high; indifferents, growing on all soils; subcalciphobes, usually avoiding lime; and calciphobes always avoiding lime. Most rock plants proved to belong to the first 3 classes, those in dry forests to the last 3. Moist forests and other wet places supported, however, more calciphilous plants, and in general the influence

of lime in the underlying rock increases with the soil moisture. In addn., plants near the borders of their ranges prove more dependent on lime than near the centers. Many species have a different relation to lime in different habitats, and in general a plant growing under relatively unfavorable environmental conditions shows a more positive response toward lime than when growing under normal conditions. At the same time indifferent species which under optimal conditions prefer poorer habitats may become more negative toward lime in less favorable places. Analytical data as to the CaO and pH values of soils from several of the localities studied are given, and from comparison with the results of other investigators it is concluded that calciphilous as applied to a plant is to be regarded as a geographical term, and alk.-soil-preferring as an ecological one.

E. T. WHERRY

Studies on the carbon nourishment of the forest. II. D. FEHÉR AND G. SOMMER. *Botan. Inst., kgl. ungar. Hochschule Bergund Forstingenieur.* *Biochem. Z.* 199, 253-71(1928); cf. *C. A.* 22, 3946.—The CO_2 production of the forest soil affects the forest air directly. This CO_2 production of the soil which is so essential for the assimilation by the trees is due to the activity of microorganisms, bacteria, protozoa and molds, which inhabit it. The CO_2 production of the soil becomes greater when the aerobic forms of bacteria predominate, and therefore care must be taken to insure good aeration of the soil. During the fall and winter, when the temp. of the soil is subjected to large variations, the effect of temp. on the CO_2 production becomes important, and when the soil temp. falls to 0° or below the respiration and the activity of the microcosmos comes to a standstill. The diminished CO_2 production is chiefly due to a rapid diminution in the no. of bacteria, the min. no. occurring in December and January. In the summer because of the greatly enhanced assimilative processes the CO_2 content of the forest air, in spite of the max. soil production, is relatively lower than in the fall, while in the winter when soil respiration is at a standstill the CO_2 content is the same as that of the ocean air. The importance of these physiol. observations is discussed in relation to the economic problem of reforestation. The N content of the forest soil depends chiefly upon the no. of nitrifying and N-fixing bacteria. The pH of the soil becomes of importance only when it falls below 5.0, as it then limits the growth of bacteria and their activity.

S. MORGULIS

Insecticidal pyrethrum: its cultivation and future possibilities. CH. CORNU. *Chimie et industrie Special No.*, 849-58(April, 1928).—A general discussion of the merits of pyrethrum as an insecticide, of the factors which militate in its favor and against it, with a description of the results obtained by C. in the course of an attempt to produce it on a com. scale in France.

A. PAPINEAU-COUTURE

Codling moth control. Experiments at Harcourt. G. T. LEVICK. *J. Dept. Agr. Victoria* 26, 459-62(1928).—Continuous use of Pb arsenate as a spray for the control of codling moth in apples seems to have led to the evolution of a moth which is partially immune to arsenical poisoning. This, together with the question of As poisoning from apples sprayed with Pb arsenate, has resulted in concn. of attention on sprays other than the arsenicals. A series of expts. was carried out to det. the effect of combined sprays of Pb arsenate and ovicidal materials, such as nicotine sulfate, lime-S and spraying oils, for codling moth control. Combined sprays of Pb arsenate with nicotine sulfate and with lime S were no more effective than Pb arsenate alone. Very good control was obtained with 2 sprayings of Pb arsenate, 5 lb. in 80 gallons H_2O , followed by 3 sprayings with a proprietary spraying oil, 1 part in 32 parts H_2O . Increasing the strength of straight Pb arsenate sprays from 4 lb. to 8 lb. in 80 gallons H_2O did not give better control. Analyses of fruit from trees receiving the different sprays indicated that spraying with oil after initial spraying with Pb arsenate tends to prevent the Pb arsenate from washing off and results in the fruit having an undesirably high As content.

K. D. JACOB

Bunt or stinking smut. The evolution of efficient control methods. D. H. ROBINSON. *Fertilizer, Feeding Stuffs and Farm Supplies J.* 13, 599-600(1928).—This is an interesting account of early attempts to control stinking smut of wheat by chem. treatments.

K. D. JACOB

Report on meetings of technical advisers in the Java sugar industry, Feb. 21 to 23, 1928 (ANON.) 28. Limestones of Nova Scotia and New Brunswick (GANDGE) 8. Limestones of the Gaspe Peninsula (Goudge) 8. S in highly dispersed form [for fungicides] (U. S. pat. 1,688,357) 18. Antiseptic, antifouling, germicidal waterproof coating composition (U. S. pat. 1,689,008) 18.

atm. of usual lead chambers from nozzles attached to the roof or side walls or below the surface of the acid which collects at the base, in such proportion that the acid collecting at the base still contains nitrous products and the acid in the last chambers contains more than that in the first chambers. An acid circulating system is described.

Sulfuric acid. CHARLES WM. FIELDING. Fr. 638,143, July 22, 1927. H_2SO_4 is produced from SO_2 gas and nitrous vitriol by introducing a mixt. of SO_2 and free O with or without oxides of N and water vapor into the bottom of a tube or series of tubes provided with mixing devices, where it comes in contact with nitrous vitriol, or H_2SO_4 strong enough to absorb oxides of N to form nitrous vitriol, which is circulated and cooled so that oxidation proceeds in the liquid phase, the nitrous vitriol acting as a true surface catalyst. Fr. 638,144 describes an app. for the production of H_2SO_4 by which SO_2 gas is forced into a vessel contg. nitrous vitriol so as to raise the vitriol in intimate contact therewith as in an air lift and continuing this intimate mixt. partly as a foam and partly as spray.

Apparatus for catalytic ammonia synthesis. FORREST C. REED. U. S. 1,689,684, Oct. 30. A pressure-sustaining vessel has connected to its cover a plurality of concentric members forming a catalytic chamber and an annular heating chamber located above the catalytic chamber. A heat exchanger is positioned in the upper portion of the heating chamber with a heater in its lower portion. Incoming gases are admitted into the heating chamber and are conducted into the catalytic chamber at points midway of the wall of the chamber and an annular baffle is positioned within the catalytic chamber for directing the flow of gases in an axial direction. Gases from the center of the catalytic chamber are conducted to the heat exchanger, and a circulating line is attached to the app. through its cover which includes a condenser and a conduit connected with the bottom of the app.

Salts of alkaline earth metals. I. G. FARBENINDUSTRIE AKTIENGESellschaft. Fr. 636,331, May 6, 1927. Salts of alk. earth metals are prep'd. from their sulfides by grinding with corresponding ammoniacal salts, preferably with the addn. of a small quantity of H_2O and final heating. Examples are given of the prepn. of $\text{Ba}(\text{NO}_3)_2$, SrCl_2 and $\text{Ca}(\text{NO}_3)_2$.

Continuous calcining of alkaline earth carbonates. REED W. HYDE (to Dwight & Lloyd Metallurgical Co.). U. S. 1,688,422, Oct. 23. Material such as lime rock, dolomite or magnesite is arranged on a traveling grate with coarser particles of the material superposed on the finer particles and heated gases are continuously passed downwardly through the material. An app. is described. Cf. C. A. 22, 2246, 4737.

Mixtures containing alkali metal hypochlorite. ALFRED OPPE. U. S. 1,689,748, Oct. 30. In order to prep. a solid mixt. of alkali metal hypochlorite and chloride, Cl is caused to react upon a suspension of alkali metal hydroxide in a neutral liquid such as CCl_4 in which neither alkali metal hypochlorite nor alkali metal chloride is materially sol.

Chlorides and bromides of silicon and titanium. I. G. FARBENIND. A.-G. Fr. 638,051, July 20, 1927. The reactions are carried out in vessels of Fe of the usual form surrounded by a casing through which water flows.

Bromides. J. H. VAN DER MEULEN. Brit. 285,015, Feb. 25, 1927. Bromides free from hypobromites are made by reacting metallic oxides, hydroxides, carbonates or bicarbonates with Br in the presence of water and of reducing agents, the decompn. of which produces only water and gases. Reducing agents suitable for this purpose are: urea, cyanamide, NH_3 , NH_4 , carbonate or bicarbonate, formamide, $(\text{CH}_2)_6\text{N}_4$, carbonates, NH_4CN , and easily decompd. org. acids such as formic or oxalic acid or their NH_4 or metal compds. or Ca nitride. Examples are given of the production of NaBr and CaBr_2 .

Anhydrous metallic chlorides. I. G. FARBENINDUSTRIE AKTIENGESellschaft. Fr. 636,339, Apr. 13, 1927. Anhyd. chlorides such as BaCl_2 , AlCl_3 , FeCl_3 , TiCl_4 are made from oxides of these metals mixed with peat or sawdust or the like, by heating and passing Cl through in the manner described in Fr. 615,772 for the production of MgCl_2 . Cf. C. A. 22, 2244.

Nitrates. ERNEST EUGÈNE NAEF. Fr. 638,551, Dec. 9, 1926. Alkali, alk. earth nitrates, NH_4NO_3 and MgNO_3 are prep'd. by the action of fuming HNO_3 with or without MnO_2 or H_2SO_4 at temps. of $50-80^\circ$ on the corresponding chlorides.

Phosphate in small spherical particles. ERNEST W. THORNTON (to R. B. Davis Co.). U. S. 1,689,697, Oct. 30. A phosphate such as a Ca or Na phosphate suitable for use in baking powder is obtained in the form of small spherical particles by spray desiccation of a soln. or suspension. Starch may be added.

Anhydrous aluminum halides. CLAUDE G. MINER. U. S. 1,688,504, Oct. 23

An acid halide gas such as HCl is passed over Al nitride and carbonaceous material at an elevated temp. (suitably about 1300°).

Ammonium sulfate. SOCIÉTÉ DE FOURN. À COKE ET D'ENTREPRISES INDUSTRIELLES. Fr. 687,977, Nov. 29, 1926. To obtain large crystals of $(\text{NH}_4)_2\text{SO}_4$ when synthetic NH_3 is passed into H_2SO_4 , any Cu or As impurities in the H_2SO_4 are pptd. and any ferric salts are reduced to the ferrous state.

Solidification of calcium nitrate. APPAREILS ET ÉVAPORATEURS KESTNER. Fr. 636,402, Jun. 21, 1927. To diminish the adherence of the layer of $\text{Ca}(\text{NO}_3)_2$ solidified by cooling on the surface of interiorly cooled rotating drums, a layer of supersatd. soln. free from crystals is interposed between the surface of the cylinder and the layer of nitrate partially crystd.

Tribarium aluminate. GEORGE W. MOREY. U. S. 1,688,054, Oct. 16. A product adapted for *pptn. of saccharates from molasses* and which comprises chiefly tri-Ba aluminate with a small proportion of BaO is obtained by heating BaCO_3 and alumina at 1150–1400° or higher.

Ferric oxide. I. G. FARBERIND. A.-G. Fr. 638,200, July 25, 1927. A finely divided Fe_2O_3 is prepd. by heating hydroxides of Fe to high temps. in the presence of water or aq. solns. of alkali salts or hydroxides.

Ferrous hydroxide. EMIL M. LOFLAND. U. S. 1,689,951, Oct. 30. Wetted Fe fragments are subjected to the action of O for a time sufficient to permit formation of $\text{Fe}(\text{OH})_2$ coatings on the fragments and these coatings are removed and recovered before they become oxidized to ferric form. An app. is described. The $\text{Fe}(\text{OH})_2$ may be preserved by an acid soln. contg. also a sol. salt of Fe.

Pure lead hydroxide. RENE DALOZE. Fr. 636,163, Oct. 12, 1926. PbSO_4 obtained, e. g., from lead chamber mud is treated with more than one equiv. of alk. earth acetate, e. g., Ca acetate. The CaSO_4 is removed and $\text{Ca}(\text{OH})_2$ added whereby $\text{Pb}(\text{OH})_2$ is formed and also Ca acetate, which is used again.

Phosphorus chloride. CLAUDE G. MINER. U. S. 1,688,503, Oct. 23. Phosphate rock is caused to react (suitably at a temp. of about 1100–1400°) with NaCl or other suitable halogen salt of an alkali metal in the presence of SiO_2 .

Potassium carbonate from chloride. J. H. BREGAT. Brit. 286,172, Sept. 22, 1927. KCl is converted into K silicate with liberation of HCl by heating with silica; the silicate is dissolved in water and treated with CO_2 to produce K carbonate and ppt. silica, which is used again. The carbonate may be used to form other salts, e. g., to form KNO_3 by reaction with $\text{Ca}(\text{NO}_3)_2$.

Sodium carbonate-sulfate. ALFRED W. GAUGER and HENRY H. STORCH (to Burnham Chemical Co.). U. S. 1,689,526, Oct. 30. Brines such as found at Searles Lake, Calif., are heated out of contact with the atm. and above a temp. (suitably about 30° or higher) beyond which the salt to be produced has a decreasing soly., in order to effect crystn. of Na carbonate-sulfate.

Trisodium phosphate. JOHN N. CAROTHERS (to Federal Phosphorus Co.). U. S. 1,689,547, Oct. 30. Na_2CO_3 is subjected to the action of H_3PO_4 of over 50% strength to form di-Na phosphate and sufficient NaOH is then added to produce Na_3PO_4 .

"Calculated iodine." WALLACE L. CHANDLER. U. S. 1,689,775, Oct. 30. A stable aq. soln. of "calculated iodine" contg. an excess of I and capable of yielding, under the action of a strong acid such as H_2SO_4 , a cryst. form of I, is prepd. by agitating an excess of I with a satd. aq. $\text{Ca}(\text{OH})_2$ soln.

Alkylating lead. CHARLES A. KRAUS and CONRAD C. CALLIS (to Standard Oil Development Co.). U. S. 1,690,075, Oct. 30. PbCl_2 is subjected to the action of Mg and EtCl in ether, without preliminary formation of ethyl Mg chloride; the temp. is maintained at about 40°, and the PbEt_2 produced is finally removed by steam.

Preventing decomposition of bicarbonates in solution. JOSEPH A. SHAW (to Koppers Co.). U. S. 1,689,059, Oct. 23. The soln. is covered with mineral oil or other suitable substantially immiscible liquid of low vapor pressure.

Hydrogen peroxide. PAUL ASKENASY. Fr. 638,090, July 21, 1927. In the formation of H_2O_2 by the action of CO_2 under pressure on BaO_2 , to the reaction mixt. are added acids, the Ba salts of which are converted into BaCO_3 by heat, or Ba salts which are converted into BaO and which are easily sol. An example is given in which 1% of AcOH or HCl is added.

Liberation of oxygen from persalts. GEORG LESCHIK. Fr. 636,106, June 17, 1927. All the O contained in persalts, such as perborate, used for washing, bleaching, etc., is liberated by adding catalysts such as MnSO_4 , K_2SO_4 , Mn lactate or tyrosinase.

Liquefying and transporting oxygen, nitrogen, etc. STUDIEN-GES. FÜR GAS-INDUSTRIE. Brit. 285,881, Feb. 24, 1927. O, N or other industrial gases of low b. p.

obtained from electrolytic or other chem. processes are liquefied and then transported in tanks to the place of use where they are gasified.

Carbon formed from hydrocarbons. A. L. MILLER (to Ault & Wiborg Co.). Brit. 286,207, Feb. 28, 1927. C is produced by the incomplete combustion of a liquid or gaseous hydrocarbon, the C-laden gases are rapidly removed from the combustion zone (suitably at a velocity of 500–6000 ft. per min.) and after cooling somewhat are treated while still traveling at high velocity to effect sepn. of the C particles, *e. g.*, by collection in an ink vehicle such as a heavy petroleum oil. An app. is described and numerous details of the process are given.

Regeneration of absorbent carbon and the like. SOCIÉTÉ ANON. DES ENGRAIS ET NOIR ANIMAL. Fr. 636,165, Oct. 12, 1926. An app. is described for the economic use of steam for regenerating C, etc., used for absorbing benzene, gasoline, etc. The boiler simply furnished the heat necessary for heating the mass and for evapg. the absorbed substance, the heat for evapg. the condensed steam being furnished by a super-heater.

Hydrogen. ARTHUR W. BURWELL (to Alox Chemical Corp.). U. S. 1,680,858, Oct. 30. In order to produce H of high purity, hydrocarbon material such as natural gas or other hydrocarbon gas is decompd. by heat, elemental C is sepd. from the mixt. of decompn. products and aromatic hydrocarbons present also are sepd. simultaneously by treatment of the mixt. with water and the methane-type hydrocarbons are converted into CO by subjecting the mixt. to a thermal decompn. at 1230–1280°, the resulting mixt. is dried, mixed with O in some excess over that theoretically required to convert the CO to CO₂ and brought into contact with a MnO₂ catalyst at a temp. below 100°, unchanged O is removed by action of glowing Cu and CO₂ is removed with NaOH soln.

Hydrogen. MARIA CASALE (née SACCHI). Fr. 638,323, July 27, 1927. H is prepd. catalytically from CO and water at such a temp. and pressure that the water remains in the liquid state, *e. g.*, at a temp. of 250° a pressure above 40.5 kg. per sq. cm. is used.

Hydrogen. COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUFACTURES' DE PRODUITS CHIMIQUES DU NORD RÉUNIS (ÉTABLISSEMENTS KUHLMANN). Brit. 286,291, March 3, 1927. Coke-oven gas or other suitable hydrocarbon-contg. gas is heated at a temp. above 1200° for a sufficient time to decomp. the hydrocarbons substantially completely with production of H. The decompn. is preferably effected in the presence of coke or refractory material which may be rendered more active by impregnation with suitable substances. An app. and various details and modifications are described.

Phosphorus. COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUFACTURES' DE PRODUITS CHIMIQUES DU NORD RÉUNIS (ÉTABLISSEMENTS KUHLMANN.) Brit. 286,290, March 3, 1927. White P is obtained by distg. in superheated steam the condensate obtained by heating phosphates, silica and coal in an elec. or other suitable furnace, or the P vapor may be reacted on to form H₃PO₄ and H.

Oxidation of phosphorus. COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUFACTURES' DE PRODUITS CHIMIQUES DU NORD RÉUNIS (ÉTABLISSEMENTS KUHLMANN). Fr. 635,432, June 2, 1927. P is oxidized by steam mixed or not with air, in the presence of binary, tertiary or quaternary metallic compds. of Si such as silicides of Cu, double silicides of Ni and Cu, or triple silicides of Fe, Cu and Ni. Cf. C. A. 22, 4738.

Sulfur. KENNETH M. BAUM. U. S. 1,689,545, Oct. 30. Ore or like material contg. elemental S is heated with an aq. soln. of ZnCl₂ of such strength that its sp. gr. is greater than the sp. gr. of molten S when at the same temp. and less than the sp. gr. of the main portion of the extraneous matter assocd. with the S, to a temp. above the m. p. of S and the floating S is sepd.

Sulfur in highly dispersed form. HANS SCHRADER and HAROLD SCHOELLER. U. S. 1,688,357, Oct. 23. S vapors are dispersed by NH₃ or NH₄ and N or other gas contg. NH₃ and the S is sepd. from the resulting fume, *e. g.*, by elec. deposition. The product is suitable for prepg. fungicides or rubber compds.

Lead product. J. D. McLACHLAN (S. J. Warren, inventor). Australia 7532, May 28, 1927. The solid materials in the flues of Pb treatment plants are treated with free O to obtain a Pb sulfate-like material.

Silica gel. MAX YABLICK. U. S. 1,687,919, Oct. 16. A soln. of a sol. silicate is treated with a sufficient quantity of an NH₄ salt such as (NH₄)₂CO₃ to form a colloidal soln. of free silicic acid and gelling in the presence of the alk. liquor resulting from the reaction is permitted and the gel is washed and dried.

"Finishing lime." VICTOR M. FREY. U. S. 1,689,237, Oct. 30. Impure dolomite is ground and decarbonated without admixture of other solid substances while agitated

at a temp. below that necessary to produce sintered or hardened particles, and the product thus obtained is hydrated.

Refining graphite and other minerals. HENRI GUYARD. Fr. 636,502, Apr. 13, 1927. Minerals are caused to travel through a conduit by means of an Archimedian screw, and jets of water-carrying air bubbles are directed through the mineral carrying the graphite particles to the top.

Plant for treating graphite and other ores. PAUL ALEXANDRE DÉSIRÉ THÉODORE. Fr. 638,088, July 21, 1927.

Active "carbomineral" absorptive material. EDOUARD URBAIN (to Urbain Corp.). U. S. 1,689,647, Oct. 30. Carbofizable vegetable material is mixed with mineral material comprising a sufficient quantity of tri-Ca phosphate to constitute at least 25% of the wt. of the finished product and H_3PO_4 , and the mixt. is agglomerated, dried and calcined at a temp. sufficiently high to eliminate most of the P other than that combined as a tri-basic phosphate. The product is suitable for absorbing gases.

Catalysts. M. LATSHAW and W. L. JUDEFIND (to Silica Gel Corp.). Brit. 286,309, March 3, 1927. Porous gels such as silica, stannic oxide, W oxide or Al_2O_3 are impregnated with a catalytic metal or compd. by charging the gel with a gaseous compd. having a reducing action (such as SO_2 , CO or H_2S) and then treating it with a soln. of a compd. of the catalytic metal such as a compd. of Pt, Ag, Ni, Cu, Pd or Fe. Further reduction may be effected with H in some cases.

Catalysts for hydrogenation and reduction, etc. I. G. FARBENIND. A.-G. Brit. 286,123, May 6, 1927. The process described in Brit. 281,218 (C. A. 22, 3500) in which catalysts are prepd. by sepg. the metal in finely subdivided form from aq. solns. of salts by action of a more electropositive metal is modified by effecting the sepn. in the presence of an org. base or an acid amide, e. g., urea or pyridine, which may be used with inert carriers on which the sepd. Ni or other catalytic metal is deposited.

Base-exchanging materials, catalysts, etc. A. O. JAEGER (to Selden Co.). Brit. 286,212, Feb. 28, 1927. Non-siliceous base exchange compds. are formed by reaction of at least one compd. such as a metallate, contg. a non-siliceous anion capable of forming the acidic portion of the nucleus of a non-siliceous base exchange compd., with at least one compd. such as a metal salt, contg. a metal element which is amphoteric in at least one stage of oxidation, to give a product alk. to litmus and preferably neutral or alk. to phenolphthalein (one at least of the reacting materials being catalytically active). An extremely large no. of examples, details and modifications are given among which are the following. Metallates derived from Al, Cr, Zn, V, Be, Sn, Pd, Ru, Rh, Os, Pt, Ti, Zr, Pb, U, Ta, Mo and W or complexes such as NH_3 or CH derivs. of these metals may be used with metal salts such as neutral or acid salts of Cu, Ag, Bi, Au, Be, Zn, Cd, the rare earths, Ti, Zr, Sn, Pb, Th, Cr, U, V, Mn, Fe, Ni, Co, Pt and Pd; borates may be used and alkali in the product may be replaced by base exchange, by NH_4 , Cu, Ag, Au, Be, Mg, Cs, Zn, Sr, Cd, Ba, Hg, Al, Tl, Ti, Zr, Sn, Sb, Th, V, Bi, Cr, Mo, U, Mn, Fe, Co, Ni, Pt or Pd and salt-like compds. may be formed by introducing anions into the product as by treatment with acids of the elements V, W, U, Cr, Mo, Mn, Ta, Cb, Sb, Se, Te, As, P, Ti, Bi, Al, Pb, Sn, Zn, S, Cl, Pt, B, Zr or Th or with complex ions such as ferro- or ferri-cyanogen, thiocyanogen or NH_3 complexes. The components may be fused together but the reaction is preferably effected between relatively dil. solns. of the components and preferably the relatively acid components are added to the relatively alk. components to maintain the reaction mixt. alk. throughout the reaction. Diluents which themselves have a catalytic action may be used and pptn. of the gels formed may be hastened by heat, pressure, agitation, or acidifying or salting-out such as with alkali or NH_4 salts, alc. or other org. compds. and the porosity of the products may be increased by addn. of substances which can subsequently be removed by leaching, combustion or volatilization. Details are given for prep. catalyst for a wide variety of specified purposes. Cf. C. A. 22, 2818.

Gaseous catalytic reactions. I. G. FARBENIND. A.-G. Fr. 638,109, July 22, 1927. In catalytic reactions such as the synthesis of NH_3 , the production of MeOH, and particularly the treatment of C by H for the production of hydrocarbons, an irregular whirling movement is given to the contact materials by a current of gas entering the contact chamber.

Condensation products of ketones and alkylated phenols. CHEMISCHE FABRIK AUF ACTIEN (VORM. E. SCHERING). Fr. 636,119, June 17, 1927. Ketones and alkylated phenols are condensed in the presence of a condensing agent such as HCl at temps. below 100° .

Condensation products of urea and formaldehyde. FRITZ SCHMIDT. Fr. 636,219, June 18, 1927. Urea or its deriva. is condensed with formaldehyde and dehydrated

in the presence of supports such as casein, cellulose or its derivs. mixed or not with softening agents, natural or artificial resins, or polymerized vinyl ethers, to obtain a spongy porous product free from bubbles.

Condensation products of formaldehyde and thiourea or thiourea and urea. SOCIÉTÉ ANON. POUR L'INDUSTRIE CHIMIQUE À BALE. Fr. 638,082, July 21, 1927. See Brit. 275,995 (C. A. 22, 2446).

Impregnating articles with phenol-aldehyde condensation products. MANUFACTURE DE MACHINES AUXILIAIRES POUR L'ELECTRICITE ET L'INDUSTRIE SOC. ANON. Brit. 286,305, March 3, 1927. The operations of drying and polymerization are effected in a heated receptacle, and impregnation and evapn. of solvents are effected in a receptacle through which a current of air or other suitable gas is passed which is supplied by a fan and heated or cooled as required. Various details of app. are described.

Sheet material comprising condensation products of urea with formaldehyde. SOC. ANON. POUR L'IND. CHIM. À BALE. Brit. 286,250, March 1, 1927. Sheets for wind shields of automobiles, flying machines, etc., are formed by uniting sheets of CH_2O -urea condensation product. Sheets of somewhat different character (details of the prepn. of which are given) may be united under the action of heat and pressure.

Artificial horn. I. G. FARBENIND. A.-G. Fr. 638,023, July 20, 1927. Artificial horn is made from casein contg. solid or liquid bases of the aliphatic, aromatic or aliphatic-aromatic series or their salts or derivs. Bases contg. OH groups such as cyclohexylethanolamine, or their homologs or acyl derivs. are particularly suitable. An example is given of a horn prepd. from casein and cyclohexylethanolamine. The aliphatic-hydroaromatic amines are prepd. by joining hydroaromatic radicals with aliphatic radicals, one or the other of which contains an OH group. Examples are given of the prepn. of cyclohexylethanolamine from cyclohexylamine and ethylene oxide, or from ethanolamine and cyclohexanone or from glycol chlorohydrin and cyclohexylamine.

Molded cork products. WM. F. GRUPE (to Boucher Cork Co.). U. S. 1,689,584, Oct. 30. In forming molded articles, granules of cork are subjected to an elevated temp. (suitably about 175°) in a partial vacuum to render the cork and the resins present in it plastic and the material is molded *in vacuo* while plastic. An app. is described.

"Catgut substitute" (for use in tennis rackets, etc.). JOHNSON & JOHNSON (Gt BRITAIN), LTD. Brit. 285,752, Sept. 9, 1927. Silk strands deprived of sericin are impregnated with glue and a softening agent such as glycerol or a glycol and a lubricant such as lard or castor oil is added to counteract any deleterious action of the softening agent. The strands may be twisted and the impregnated cord may be water-proofed by exposure to vapors of CH_2O or by treatment with other tanning agent.

Vegetable glue. IRVING F. LAUCKS and GLENN DAVIDSON (to I. F. Laucks, Inc.) U. S. 1,689,732, Oct. 30. A glue is formed by reaction of a vegetable seed flour high in protein such as soy-bean flour and an alkali metal hydroxide in an aq. medium. NaOH and Ca(OH)_2 may be used together.

Molds for plastic materials. SOCIÉTÉ INDUSTRIELLE DE CAOUTCHOUC D'ARGENTEUIL. Fr. 638,010, June 30, 1927. Molds for rubber, celluloid, etc., are made of steel surrounded with a casting of Al for lightness and rapid absorption of heat.

Molds for plastic materials. "SICA" (SOCIÉTÉ INDUSTRIELLE DE CAOUTCHOUC D'ARGENTEUIL). Fr. 638,008, June 25, 1927. The interior of molds for rubber, celluloid, etc., has a coating of metallic regulus, e. g., an alloy of Sb and Pb.

Waterproofing and coating paper, leather, wood, fabrics, etc. A. JEREMIAS. Brit. 286,396, Dec. 20, 1926. An emulsion of rubber, collodion or other suitable material insol. in water is applied as a coating and the material in the coating is then converted into insol. form by a fixing agent, e. g., a metal salt such as alum, Al acetate or chrome alum. Numerous details, examples and modifications are described.

Protective coatings on wood, metal or other materials. PERRY W. TURNER. U. S. 1,689,567, Oct. 30. After applying a protective coating such as an adhesive varnish contg. kieselguhr, kaolin and ZnO or Ti oxide, a moist fabric is applied over the coating before the latter is dry, is allowed to dry and shrink on the article, and the fabric is impregnated with the coating compn.

Antiseptic, antifouling, germicidal, waterproof coating composition. ARTHUR BIDDLE (to United Products Corp. of America). U. S. 1,689,008, Oct. 23. A compn. suitable for use on plants or walls, etc., comprises a poisonous As compd. such as Ca arsenate 20, casein 3 and rubber latex 10 parts. This mixt. may be dild. with water up to 4000 parts for use as a spray.

Acoustic diaphragms of thin porous metal. NEWMAN H. HOLLAND (to Bell Telephone Laboratories). U. S. 1,689,030, Oct. 23.

Sound records. W. T. SMITH, W. A. SMITH and S. H. WOOD. Brit. 285,965, Nov.

23, 1926. In recording for the manuf. of records in tape form, the sound grooves are first made in wax in the usual way, Cu is then deposited on the wax to form a matrix and from this the record is impressed on a strip of celluloid or like material.

Use of radioactive material for making time records, etc., on sensitive strips of various recording apparatus. J. A. TIEDEMAN (to British Thomson-Houston Co., Ltd.). Brit. 286,299, March 3, 1927.

Polish for metal, leather, furniture, etc. GEORGE W. DARLINGTON. U. S. 1,689,864, Oct. 30. Gasoline 6, eucalyptus oil 1, an aq. soap soln. (contg. 1.25 lbs. soap per 3 gals. water) 1 and infusorial earth 1 part.

Stencil sheets. H. SIMON. Brit. 286,466, March 15, 1927. In making stencils comprising Yoshino paper coated with a compn. which includes oily softening agents, a protective coating impervious to the oily material (such as protein or resinous material or cellulose esters or ethers) is applied to the sheet to protect the typewriter platen, etc., from action of the oily substance. Examples are given of protective compns. formed of an alk. casein soln. with glycerol or sugar, an alc. soln. contg. varnish and Na oleate, and an alc. soln. of palmitic acid and Na oleate.

Decolorizing substances. SOCIÉTÉ ANON. DES ENGRAIS ET DE NOIR ANIMAL. Fr. 636,204, Oct. 15, 1926. Non- or slightly volatile acids, *e. g.*, H_2SO_4 or H_3PO_4 , are incorporated in active C such as animal black to prevent shrinking when the C is dried.

Activation of gases. ALEXANDRE FOLLIET. Fr. 637,891, July 19, 1927. Gases, such as CO and H, are heated to 500–1000° under a pressure of 5–100 kg. in a suitable app. having inert walls, and cooled if necessary before entering the catalyst chambers.

Emulsions. I. G. FARBENIND. A.-G. Brit. 286,252, March 1, 1927. Semi-solid or friable masses sol. in or emulsifiable with water are obtained by sulfonating wool fat (which may be mixed with wool fat fatty acids) in the presence of a phenol, and suitably in the presence also of solvents such as tetrachloroethane or other chlorohydrocarbon, a hydroaromatic compd. or CS_2 .

Detergent. STEPHEN D. FRANKO (one-half to Harry E. Dyer). U. S. 1,688,540, Oct. 23. A compn. suitable for cleaning hats or leather goods is formed from water 1 gal., S 4 oz., oxalic acid 3 oz., Pb acetate 2 oz., Na_2CO_3 4 oz., NaHCO_3 2 oz., Na_2SO_3 8 oz., rock alum 2 oz., H_2O_2 3 oz. and a perfume.

Detergents. BRITISH DVESTUFFS CORP., LTD., J. BADDILEY AND E. CHAPMAN. Brit. 286,197, Sept. 21, 1926. Compns. for cleaning and polishing walls, tiles, stone-ware, glass, metal and painted and polished surfaces are formed of the sulfonic acids described in Brit. 274,611 (C. A. 22, 2268) and Brit. 279,990 (C. A. 22, 3042) or their sol. salts in the form of aq. solns. or pastes which may be mixed with an org. solvent such as benzene, naphtha, petroleum spirit, chlorinated hydrocarbons, etc. Thickeners, coloring agents, abrasives or soap also may be added. Cf. C. A. 22, 4741.

Cleaning and degreasing metals. DR. ALEXANDER WACKER GES. FÜR ELEKTROCHEM. INDUSTRIE G. M. B. H. Fr. 636,405, June 21, 1927. An app. for cleaning metals by a liquid such as trichloroethylene or benzene comprises 2 closed vessels, one above the other and provided with an arrangement to establish a difference of pressure to bring the cleaning liquid from the lower to the upper vessel contg. the metals and to the lower again without coming in contact with circulating or closing parts.

Lining for metallic vessels. TAKANOSHIN DOMOTO. U. S. 1,688,857, Oct. 23. A compn. suitable for lining cans for holding soy or "miso" is formed of rubber 10, C_6H_6 100 and Al soap 5 parts.

Apparatus (with a rotating horizontal drum carrying an internal spiral) for oxidizing ground lead, etc. FREDERICK W. ECKFELDT (to John T. Lewis & Bros. Co.). U. S. 1,690,068, Oct. 30.

Composition for transferring designs. OLIVER L. DAVIS (to Joseph Walker Co.). U. S. 1,688,117, Oct. 16. Cumar gum, rosin, carnauba wax and stearic acid are used with a coloring matter comprising ultramarine blue and a special white ink contg. litho varnish and "Titanox" (contg. TiO_2 and pptd. BaSO_4).

"Antifreeze composition." JAMES R. PAUL. U. S. 1,689,153, Oct. 23. A compn. suitable for use in automobile radiator systems comprises substantially equal quantities of $\text{Na}_2\text{S}_2\text{O}_4$ and CaCl_2 , a smaller quantity of tartaric acid, and water.

Pigmented exfoliated shell. SIDNEY RAUSCHENBERG. U. S. 1,689,842, Oct. 30. Exfoliated natural shell in flaked form is immersed in a chem. soln. such as an aq. soln. of AgNO_3 and NH_3 and the mixt. is boiled and stirred, a precipitant such as $\text{K}_2\text{Cr}_2\text{O}_7$ soln. is added and the admixture is further boiled and stirred. The product is suitable for decorative purposes.

Improving frictional surfaces. BRITISH DVESTUFFS CORP., LTD., CECIL JOHN

TURRELL, CRONSHAW, JAMES BADDILEY AND ERNEST CHAPMAN. Fr. 637,850, July 18, 1927. See Brit. 278,495 (C. A. 22, 2645).

19- GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

The manufacture and properties of glass and their application in illuminating engineering. S. ENGLISH. *Glass* 5, 212-4, 262-9, 310 3(1928).—A review. Transparency and color are discussed together with methods of decolorizing. The various types of daylight glasses are described. Diffusing glasses are divided into 3 groups, (1) opal glasses, (2) etched or sand-blasted glasses and (3) glass with a prismatic or irregular surface. Efficiency of diffusion is equal to scattering power divided by absorption and in opal depends upon amt. of material sepd. from soln., size of particles and difference in n of the glass and the particles. The min. diam. of the particles should be that of the wave length of the light considered. Brittleness in opal glass is due to formation of dendritic crystals in the glass from working at too low a temp. Etched or frosted glass has a smaller absorption than opal and diffuses all wave lengths equally. Better transmission is obtained when the etched surface is faced toward the source of light. Thus inside frosted bulbs are more efficient than outside frosted. A detailed diagram and description of the bulb-frosting process are given. W. H. RISING

The relationship between the water-solubility and composition of glasses. JOHANN ENSZ. *Glastech. Ber.* 5, 449-76, 509-19(1928).—Exptl. glasses were crushed and graded between circular sieves to 1-5 mm. diam. The grains were washed with abs. alc. dried at 100-120°, and 18 g. quantities boiled with a salt soln. boiling at 107°, in a 500 cc flask with a reflux condenser for 7 hrs. After cooling the soln. was filtered through silk bolting cloth of 0.085 mm. mesh, the finely pptd. silica being allowed to pass through. The grains were washed with distd. water at 100° and the filtrate was evapd. and analyzed. A summary of various theories is given. When SiO_2 is replaced by MgO , CaO , ZnO , BaO , PbO , B_2O_3 , or Al_2O_3 in a glass having the compn. 82 SiO_2 , 18 Na_2O the most resisting glass is obtained with Al_2O_3 , the other oxides following in the order of ZnO , CaO , B_2O_3 , MgO , BaO , PbO . Contrary to previous beliefs MgO glasses contg. less than 5% MgO are less stable than the corresponding CaO glasses. The belief that B_2O_3 increases resistance up to about 12% and above this point causes a decrease in resistance is confirmed. The marked max. in the soly. curves which Peddle (C. A. 16, 3180) found for K_2O - Na_2O in lead and lime glasses was not verified in this series, only a very slight max. being noted. The absence of maxima in glasses in which the oxides of bivalent and trivalent alkali elements were present in varied proportions was definitely established. E. VALDEN

The Fourcault process of drawing sheet-glass. K. LOSSEN. *Glastech. Ber.* 6, 121-34(1928).—A complete description of the Fourcault process with details of the construction of the float and drawing tower. The relations between the thickness of the sheet and (1) the drawing speed, (2) the viscosity of the glass, (3) the depth of immersion of the float are discussed. The way in which devitrification limits the temp. range of the molten glass and its compn. is explained with reference to the phase diagrams of Morey and Bowen. Raising the temp. of the molten glass is beneficial for many reasons and gives a flatter surface but the temp. variation is limited to 25° because of the cooling conditions above the float. Different dispositions of 6 machines at the working end of a tank are illustrated and the dimensions for most efficient working are given. E. VALDEN

The coloring of glass by metallic sulfides. HERMAN HEINRICHS. *Glastech. Ber.* 6, 51-4(1928).—The sulfates of Fe, Cd, Ni and Mn were reduced to sulfides by heating with powd. Al, Zn, Mg and Fe. CdSO_4 is easily and quantitatively reduced to CdS by Mg. H. attempts to obtain glasses with dissolved sulfides by reducing the sulfates with powd. metals during melting. FeS was obtained in glasses contg. 67-77½ SiO_2 , 7½-10 CaO , 14½-19 Na_2O through reduction of FeSO_4 by Al, Mg and Fe. Zn gave no sulfide. Batches high in water content gave lighter colored glasses through loss of sulfide as H_2S . As much as 1% FeS could be dissolved in these glasses. The reduction of CdSO_4 in glasses was accomplished by Al but not with Zn or Mg. The glass was colored a light brown which changed to yellow on reheating. CdS is much less sol. than FeS in the glasses examd., though its soly. increases with increasing alk. of the glass. The soly. of CuS and NiS is less than that of CdS . E. VALDEN

Wollastonite crystals in devitrified glass. M. BELLIERE. *Glass* 5, 159-60(1928).—In tearing down a glass furnace glass was found to have penetrated the floor cracks and there devitrified. The uncrystd. liquid has flowed away, leaving a skeleton-like mass of crystals. These on measurement proved to be wollastonite. Measurements are given together with several drawings of the crystals. W. H. RISING

Measuring temperatures in the glass industry.* H. MIETHING. *Sprechsaal* 61, 526-8, 546-8(1928).—The necessity and advantages of keeping a close and accurate record of temps. in glass-melting tanks are stressed. The use of the thermocouple in tanks has decided disadvantages. The Ardometer, a radiation pyrometer, is especially adapted for recording continuous temp. for long periods; the optical pyrometer is suitable for intermittent temp. measurements. The Ardometer is a combined radiation pyrometer with the thermocouple principle. The methods of attaching the Ardometer, controls, and measuring and recording the temps. in a glass tank are described and illustrated. A discussion on the use of base metal thermocouples in annealing furnaces is included. R. A. HEINDL

Glass tank operation improved by use of preheated air. W. DYRSSEN. *Glass* 5, 10(1928).—A brief description of a continuous regenerative type air heater for a glass tank fired with natural gas. H. P. HOOD

Effect of combustion conditions in glass-furnace operation. D. J. MCSWINEY. *Glass* 5, 155-6(1928).—A brief discussion of the maintenance of balanced combustion conditions. The condition of the combustion atm. largely detcs. the degree of glass decolorization by Mn. A smoky flame is a common cause of low or dirty colored glass and may be a cause for seed. The use of a soft flame is said to give glass of better working properties, probably influenced by the amt. of salt cake, As or other reducible materials in the glass. H. P. HOOD

The electric heating of glass annealing furnaces. K. TAMELE. *Glastech. Ber.* 6, 225-42(1928).—A review of the various forms of glass elec. annealing furnaces used in the U. S. with descriptions of the various methods of temp. control and the construction of the heating units. E. VALDEN

Water cooling as applied to glass tanks and furnaces. F. F. CARTY. *Glass* 5, 54-9(1928).—A description of the development of a method of water cooling glass tank walls and throat. Buckstays are cooled to prevent bending. The effect of wall cooling becomes most noticeable when the wall thickness has been reduced to 4 in. It is possible to continue the operation of a furnace even after portions of the tank walls are gone. The coolers are made of rolled steel plates about $\frac{5}{16}$ " or $\frac{3}{8}$ " thick pressed into shape and the joints welded. Water flow is adjusted to maintain an outlet temp. about 180° F. Reduced costs and increased production are claimed upon larger refractory life, lower building, operative and maintenance costs, and continuous operation for much longer times. Lower fuel costs are based on the walls retaining their thickness for a longer period and thus maintaining the original furnace design and efficiency. H. P. HOOD

Electric firing and stained glass. B. M. PEARSON. *Ceramic Age* 11, 214-7(1928).—The old gas-fired type of furnace for firing stained glass has been replaced by elec. furnaces heated by nichrome elements. By this means better temp. control is claimed as well as better atm. conditions in the furnace, resulting in less spoiled ware. An historical account is given of the stained glass industry in England from medieval times. W. H. RISING

Short course on refractories for glass makers. K. ENDELL. *Glastech. Ber.* 5, 601-2(1928). E. VALDEN

Some measurements of the depolarization effect in colloidal colored and opal glasses. B. LANGE. *Glastech. Ber.* 5, 477-86(1928).—The degree of polarization of the light scattered at right angles to the incident beam depends on the size of the colloidal particles. By measuring this degree of polarization L. obtains an indication of the size of the particles present in the glass. For CdS glasses and for a glass colored by x-rays the values obtained were so low that L. concluded that the coloring is not of a colloidal nature. A comparison between gold sols and gold sapphire glass showed the method to be valid. E. VALDEN

Stresses and strains in glass. FRIEDRICH RINNE. *Glastech. Ber.* 6, 65-76(1928).—R. discusses the at. and mol. stresses in substances and then considers the internal stresses resulting from external forces. The stress ellipsoid with its slip-planes, stress diagrams with linear and curved coordinates, and isoclinic and isodynamic stress figures for glass are defined and explained. The method of realizing these experimentally by means of polarized light is mentioned and the case of a glass disk heated by a point source at the center worked out. R. discusses the stresses set up in glass under mech.

strain, the progress of a crack and the disappearance of the stresses in the glass, the optical phenomena resulting from a scratch on the surface with stress figures, and the conchoidal fracture of glass by the impact of a steel ball. E. VALDEN

Some results on the behavior of glass under concentrated loads. OTTO GRAF. *Glastech. Ber.* 6, 183-6(1928).—The cone-shaped fracture which occurs when a sphere is in contact with a glass surface and a load applied is investigated. It was found that the surface of the cone was smooth when the load was applied smoothly and that steps were formed when the load was increased by jerks. The angle of the cone varied with the time taken to apply the load, being greatest when the load was applied suddenly and decreasing to a const. value. E. VALDEN

The durability of sheet glass. G. KEPPELER AND F. HOFFMEISTER. *Glastech. Ber.* 6, 76-89(1928).—Two methods were used: (1) A trough made of 2 glass plates sepd. by a Para-rubber band and suitably clamped was filled with water and kept at 80° for 3 hrs. in a thermostat. Fifty cc. was withdrawn and titrated with 0.01 N H₂SO₄, methyl red being used as indicator. The surface of the water was covered with paraffin. (2) A powder method in which the glass was sifted between sieves 30 and 50 per cm., washed with alc., dried, placed in 100 cc. water at 100° for 5 hrs. The water was filtered and evapd. in a Pt dish and the residue obtained. The results of these methods were compared with the values obtained from the chem. compn. While the values obtained by the powder method and the values obtained from the ternary diagram generally agreed, the results obtained by the cell method varied. The first 2 methods put most of the glasses in class III. The cell method put them in classes II, III and IV according to the classification of Mylius. The glass surface seems to be affected by methods of manuf. and previous treatment. Polishing increases its susceptibility to attack, probably because of the removal of the surface layer. Old window glass had a very high resistance on account of the removal of the soda in the surface layer. For this glass the powder method gave a rating in class III, the cell method class I. Sheet glass manufactured by the Fourcault process was the worst from the point of view of weathering. Blown sheet glass and cast plate glass were of equal quality or on the boundary of classes II and III on the Mylius scale. E. VALDEN

Gases in glass. HERMANN SALMANG AND ALFRED BECKER. *Glastech. Ber.* 5, 520-37(1928); cf. C. A. 22, 1661.—The exptl. details in connection with the detn. of gases in glass are described. Glasses which have been degasified at a high temp. in an evacuated furnace gave no gases after having been held at somewhat lower temps. in various gases at atm. pressure. S. and B. believe the gases in glass to be held in chem. combination rather than in merely phys. soln. Glasses contg. Na₂SO₄ yield SO₂ and O₂ in the ratio of 2:1 as required by the decompn. of SO₃. Water was found in all the glasses tested, varying in the carbonate glasses from 0.02 to 0.053% by wt. H. P. H.

An improved hot-wire glass cutter. J. ALLEN BAKER AND HARRY H. HALDEMAN. *J. Chem. Education* 5, 1289-91(1928). E. H.

Chemical and thermal resistance of laboratory glassware. ARNALDO MAURI. *Le verre* 7, 143(1927).—A review of previous work. E. VALDEN

Chemical and thermal resistance of laboratory glassware. ARNALDO MAURI. *Le verre* 7, 151-4(1927).—The glasses examd. were Jena (green line), Jena 20, Murano 22, Murano 23, Pyrex Labo Boromica. Analyses of the glasses are given. The effects of 0.1 N solns. of H₂O, HCl, NH₄OH, NH₄Cl, (NH₄)₂CO₃, NaOH, Na₃PO₄, Na₂CO₃ and Na₂S on the glasses were detd. at 120° in the autoclave. The glass was ground to a mesh of 8 per cm. and the loss in wt. detd. A series of expts. was made by boiling the following solns. in flasks for 2 hrs.: HCl (N and 0.1 N), HNO₃ (0.1 N), H₂SO₄ (0.1 N), (COOH)₂ (0.1 N), H₂S (0.1 N), SO₂, NH₃ (0.1 N and N), NH₄Cl (N), (NH₄)₂CO₃ (N), NaOH (0.1 N), Na₃PO₄ (0.1 N), Na₂CO₃ (0.1 N), Na₂S (0.1 N), (NH₄)₂S (0.1 N). The loss in wt. was detd. The thermal resistance was measured by chilling lab. ware from 150° to 15°. E. VALDEN

Window glasses transmitting ultra-violet rays. S. ENGLISH. *Glass* 5, 338-40 (1928).—A description of exptl. glasses leading to the development of Holviglass. Spectrograms are given for alkali silicates; the best quality of Fontainbleau sand melted in unglazed porcelain crucibles is used. The admixt. of either soda, potash or boric oxide with silica seriously reduces its power of transmitting ultra-violet. Addns. of CaO, MgO, Al₂O₃, B₂O₃, ZrO₂, ZrO and BaO were tried. Na₂O, B₂O₃ and SiO₂ glass gave the highest transmission limit, 262 μ in 2 mm. thickness. No relationship between silica content and transparency was found. Fe oxide causes reduced transparency. Alkali added as the carbonate proved to be much better than either the sulfate or nitrate. Spectrograms and curves showing the effect of solarization by sunlight and the Hg arc on various ultra-violet transmitting glasses are included. H. P. H.

Physical and chemical properties in the five-component system sodium, potassium, calcium, aluminum, silicates. (The glassy state.) E. BERGER. *Glastech. Ber.* 5, 569, 597(1928).—The investigation of this five-component system was conducted by making kg. melts in sets of forty. The density, expansion, n , dispersion and water and alkali soly. were detd. The furnace was cooled down slowly after each run and the glass examd. under a magnification of 10 X to 20 X. The various melts were divided into 3 classes: (1) glassy, (2) partially crystd., (3) totally crystd. or infusible at 1500°. The various const. were plotted according to Zschimmer's system of projection. A few typical projections are given as well as the address from which a complete set may be obtained.

E. VALDEN

Silicate analysis. ALFRED THURMER. *Glastech. Ber.* 5, 537-8(1928).—T. presents notes on silicate analysis gathered from the literature. References are given.

J. A. GRANT

Manufacture of gray brick. L. P. COLLIN. Can. Dept. Mines, *Mines Branch* No. 690, 8(1928).—A description of the process of mfg. gray brick in Pennsylvania is given. About 26 lbs. of MnO_2 is added to the clays for 1000 bricks to give the color to the burned bricks. The burning temp. is from cone 8 to cone 10. By using a strong reducing atm. at the end of the burn, various shades of gray are obtained.

L. W. RIGGS

Efflorescence on brickwork. W. ANGUS MCINTYRE. Building Research Sta. *Brit. Clayworker* 37, 252-5(1928).—The Building Research Sta. at Watford has commenced an investigation into certain aspects of the problem of efflorescence. M. discusses the value of the work of previous investigators and states that all efflorescences consist of salts which are sol. in H_2O , although the degree of soly. may vary enormously. The fact that these substances are all sol. in H_2O indicates that the best way of removing them when they appear on brick walls is washing in plain water. Salts of Na, K, Mg and Ca are present in raw brick clays and are not fully decompd. in the kiln. Sulfates meet with little or no decompn. during the firing. $BaCO_3$ is at present used to overcome the bad effects of the sulfates. M. also discusses other sources of sol. salts and how these sources may be eliminated.

R. A. HEINDL

After diaspore—what? A. F. GREAVES-WALKER. *Ceram. Age* 12, 92-3(1928).—The present reserves of diaspore are about 1 million tons. Within a few years there will be a shortage. Possible substitutes are (1) cyanite, (2) bauxite, (3) Georgia kaolins. A practically inexhaustible deposit of cyanite is located in western N. Carolina. Since it occurs in a siliceous schist it would have to be washed and also calcined before using which would increase its cost over that of diaspore. Bauxite requires much higher burning than cyanite but has been used in refractories with success. Georgia kaolins are plentiful and have been used for a long time. They also require calcining if substituted for diaspore.

W. H. RISINO

Notes on production of cream-colored bodies. GEORGE H. BROWN. *Ceramic Age* 11, 77-9(1928).—Several series of clay mixts. of rutile and TiO_2 with clays contg. various Fe contents were prepd. and burned. With low Fe_2O_3 contents a light cream color was obtained but with increasing Fe_2O_3 the color ranged from tan to greenish gray. Conclusion: (1) Rutile is satisfactory for use in the development of cream-colored vitreous floor tile bodies. (2) Better colors are secured in bodies which are free from ball clay and low in Fe_2O_3 , as the color secured from TiO_2 or rutile is largely dependent upon the proportions of rutile and Fe_2O_3 . (3) The use of TiO_2 as a coloring agent in place of rutile has great possibilities, and satisfactory colors can be secured in vitreous bodies using ball clay if TiO_2 is utilized instead of rutile. TiO_2 is very hard to grind, has a tendency to crystallize on a clay body, and has an uncertain effect on the body. Rutile gives variable color effects owing entirely to variations and irregularities in the burning.

W. H. RISINO

Lignin extract. A dry body strengthener makes a cheap organic binder. ROBERT M. KING. *Ceram. Ind.* 11, 43-5(1928).—Lignin ext., obtained in either the liquid or powder form, was tried out on representative clay bodies as a dry body strengthener. In all types it produced a marked increase in dry strength with no increase in shrinkage. Advantages of this cheap binder are: (1) body strength may be increased without increase of plastic clay content; (2) excessive shrinkage may be reduced by substituting lignin ext. for some of the plastic clay, thus saving an expensive material as well as reducing shrinkage; (3) drying and aging processes are shortened, thus cutting expense on these operations. Curves are given.

W. H. RISINO

Notes on the English and German refractories industry. STUART M. PHELPS. *Am. Refractories Inst., Tech. Bull.*, No. 25, 4 pp.(1928).

E. H.

Kaolinic refractories and their properties. MARK J. TERMAN. *Heat Treating and Forging*, 14, 642-3(1928).—Processing a kaolinic material by a new method, a re-

crystd. refractory brick is obtained having a max. uniformity of quality and size. Its ratio of $\text{SiO}_2\text{-Al}_2\text{O}_3$ is the same as that of other clays; its m. p. is 3200°F. in an oxidizing and 3165°F. in a reducing atm.; up to 2900°F. it has no permanent vol. change and only a slight shrinkage up to 3000°F. ; its av. coeff. of expansion is 242×10^{-6} ; it shows unusual resistance to spalling, does not "grow" under continued exposure to heat, and has unusual load-bearing capacity. Some applications are outlined. J. BALOZIAN

Refractoriness of molding sand. J. F. McMAHON. *Can. Dept. Mines, Mines Branch No. 690*, 9-24(1928).—The procedures for detg. the softening point of the entire sand and the clay substance are described, also the draw-trial and Sagger tests.

L. W. RIGGS

X-rays in ceramics. T. N. McVAY. *Ceram. Ind.* 10, 629(1928).—Although x-rays have not been widely applied to ceramics there are some possible applications such as: examn. of at. structure to det. directional properties or fibering, study of the fine structure to det. mineralogical character, detn. of internal strain of porcelain insulators and detn. of difference in expansion between glaze and body. M. found kaolinite as the principal mineral in an English residual china clay and a Georgia secondary clay. Mullite appeared with both clays fired at 950° and the amt. of mullite increased with an increase of temp. An x-ray photograph of unannealed glass showed lines characteristic of materials having internal strain, while a sample of a spark plug did not give a strain diagram.

Some suggestions for enamellers on the control of opacity. A. I. ANDREWS. *Ceram. Industry* 11, 266-7(1928).—Ten enamel compns. were studied. No definite relation could be traced to any particular constituent nor to the total amt. of flux. Increase of SnO_2 up to 20% increases opacity, though the effect decreases for the larger % SnO . Over 10% adds but little to the opacity. If less than 10% is used, auxiliary opacifiers aid in opacity. SnO_2 used in the mill is of a good white with a slight tendency toward a blue.

Wall tiles from sheet steel. ANON. *Ceram. Age* 11, 117 8(1928). "Porcelain" is a new type of enameled sheet steel wall tile.

W. H. RISING

They purposely produced defective enamel ware to study defects and remedies. K. B. STRONG AND E. R. BRAUNER. *Ceram. Ind.* 11, 59 61(1928).—A series of expts. was made in which the mech. operations such as spraying and burning were varied to observe the effect and det. the cause of the many faults which occur in enamel ware. Conclusions: (1) An underfired ground coat causes fish scaling not only in the ground coat but in all cover coats. (2) An overfired ground coat develops another type of fish scale in the ground coat which is smaller than that of the first case and which, if it appears in the first cover coat, is only a small dark speck. (3) Prolonged grinding of the enamel tends to produce pimples. (4) Too long aging of the enamel slip tends to develop pimples. (5) An underfired cover produces pimples while pinholes appear in succeeding coats. (6) Hairlines are produced by uneven heating which is due to uneven spraying, uneven thickness and cold spots or shadows on the ware. (7) A decidedly overfired ground coat causes pimples and blisters in succeeding coats.

Imitating frosted or stained glass, etc. R. GOLDSCHIEDER and I. TUSCHINSKY. *Brit.* 286,012, Nov. 29, 1926. A wire gauze or other suitable fabric is impregnated with a lacquer (which may comprise a condensation product of urea and CH_2O) and granulated glass or the like is applied to the surfaces. Pattern effects may be produced on the surfaces if desired.

Apparatus for forming and cooling sheet glass. JOHN L. DRAKE (to Libby-Owens Sheet Glass Co.). U. S. 1,688,528-9-30, Oct. 23.

Apparatus for making tumblers, bulbs or other glass articles. THEODORE H. SLOAN (to Macbeth-Evans Glass Co.). U. S. 1,689,975, Oct. 30.

Apparatus for and method of handling sheet glass during annealing. FRANK W. PRESTON. U. S. 1,689,048, Oct. 23. Structural features.

Annealing kilns for plate glass. PITTSBURGH PLATE GLASS COMPANY. Fr. 636,342, May 25, 1927. Constructional features.

Uniting porcelain and glass. R. THILENIUS. Brit. 285,919, Feb. 25, 1927. In making Hg rectifiers, vacuum tubes, Röntgen ray tubes and similar app., porcelain and glass parts are united by melting, the glass being selected to have a coeff. of expansion of not more than 0.000005 and to have about the same m. p. as the porcelain. Gas or acetylene burners may be used for the fusion. Similarly, glass inspection surfaces may be fused into porcelain tubes.

Refractory material. HARTFORD-EMPIRE COMPANY. Fr. 636,308, Feb. 28, 1927. A refractory material contg. principally Al_2O_3 and SiO_2 is described. An example contains 4 parts of crude diaspore or equiv. aluminous earth, 4 parts calcined diaspore or equiv., 2 parts calcined Al_2O_3 , 3 parts siliceous plastic clay and 5 parts addnl. clay.

Apparatus for measuring the shrinkage of bricks, etc., during their drying or burning in kilns. FRANKLIN W. GUNTHER and GEORGE P. FISHER (to National Fire Proofing Co.). U. S. 1,688,330, Oct. 23.

Regenerative channel oven for burning bricks, heating steel billets, etc. HEINRICH KOPPERS (to Koppers Development Corp.). U. S. 1,687,774, Oct. 16. Structural features.

Tunnel for drying brick, etc. CLAUDE E. FULLER (to New York Brick Handling Corp.). U. S. 1,688,306, Oct. 16. Structural features.

Apparatus and air current system for drying ceramic ware. THOMAS H. RHOADS (to Proctor & Schwartz). U. S. 1,689,082, Oct. 23.

Muffle kiln for firing pottery, etc. T. SIMPSON. Brit. 285,935, Oct. 21, 1926. Structural features.

Porcelain. PORZELLANFABRIK PH. ROSENTHAL & Co., A. G. Fr. 638,438, July 29, 1927. The constituents for making hard porcelains, particularly for elec. insulators, are so chosen that the compds. of SiO_2 have the same form when the porcelain is baked as that of the clay used.

Enameling small bath room fixtures or other articles. PAUL F. TITCHENER (to E. H. Titchener & Co.). U. S. 1,689,062, Oct. 23. The articles are dipped in an enameling soln. and before drying are dipped in a thinning soln. of the enameling soln. and then dried while in motion. An app. is described.

Enameling oven suitable for treating wire. CHARLES L. HEISLER (to General Electric Co.). U. S. 1,688,710, Oct. 23. Structural features.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Improving the quality of cement. H. RICHARZ. *Pit and Quarry* 17, No. 2, 45-8 (1928).—A general discussion of the effects of incorporating puzzolanas and water-repellent materials into cement.

Fuel economy in burning portland cement clinker. ROBERT D. PIKE. *Ind. Eng. Chem.* 20, 1155-63 (1928).—The present-day rotary kiln has a thermal efficiency of about 25%. The theoretical requirements for increasing thermal efficiency are pointed out and improvement along those lines is suggested as preferable to the use of waste heat boilers.

Modern concrete construction. Piled foundations. J. W. STEWART. *Munic. Eng. Sanit. Record* 81, 530-1 (1928).—S. describes the Raymond piling system (tapered) and gives a formula for working loads.

Reinforced concrete roads. The lack of reliable data. P. G. N. WORKMAN. *Munic. Eng. Sanit. Record* 81, 485 (1928).—A discussion as to whether some reinforced concrete roads were suitable.

Road surfacing materials. W. J. A. BUTTERFIELD. *J. Soc. Chem. Ind.* 47, 293-9T (1928).—Road surfaces today must be studied principally with respect to driven heels, not hauled wheels. Rubber has a high coeff. of friction on polished or smooth surfaces, even on snow and ice, in the absence of a lubricant (water). The surface

must also give a good foothold to iron, leather, hoofs, etc. It must offer little resistance to the roll of wheels, must be durable, and be unaffected by deposits of leaves, horse-droppings, oil, etc. The water-bound macadam road disintegrated under motor traffic because the tires sucked out the dust binder. As a result various kinds of tar were tried. Finally refined or dehydrated coal tars were found to be the most satisfactory. Specifications in Britain for successive years 1911 to 1928 are given. The viscosity is important (modified Engler, modified Redwood). Results obtained with these 2 instruments are tabulated and compared. Tar when applied to a road surface undergoes more or less rapid changes because of the oxidation or polymerization of some of its compds., and these changes are responsible for the "drying" or "setting" of the coating. Tar carries, or should carry, in itself a natural vehicle functioning like the drying oils and turpentine in paint and, like paint, its effects and durability cannot be properly judged by observation of it while "wet." In this respect tar differs from asphaltic bitumen which has no constituents to bring about this drying or setting. The best tars should contain enough, but not too much, "free carbon" to function as a "filler" in asphalt; not enough phenolic substances to indicate any extent of water sol. constituents or constituents very readily subject to polymerization and oxidation; a sufficiency of high-boiling oils of a highly viscous character; enough naphthalene to indicate that a large proportion of its assoc. liquid hydrocarbons are of a chemically stable nature, but not enough to indicate attendant destruction of other valuable hydrocarbons; enough naphthalene to effect a sensible reduction in the consistency of the tar, and a consequent increase in consistency as the naphthalene evaps., but not so much that its rapid volatilization impairs the soundness of the coating. The rock and lake asphalts are usually restricted to urban roads and fall outside the scope of the paper. Their characteristics and analysis are, however, discussed. Asphaltic bitumens from petroleum, unlike tar, do not dry or set. They must, therefore, be heated till sufficiently fluid to flow over the road surface, or be squeegeed into it to form a coat of uniform thickness, and to penetrate sufficiently to form a good bond. A better plan is to mix the hot asphaltic bitumen with the proper proportion of suitable aggregate before laying. Portland cements should not be used for mixing with the asphaltic bitumen. Good results are often secured by mixing tar and asphaltic bitumen. The surface after laying must always be covered with grit to improve traction and to prevent tires from picking up the tar while still "wet." The effects of dirt and washings from tar- and asphalt-surfaced roads on vegetation and fish are discussed. All bituminous road surfacings involve a certain danger to fish life. Concrete surfaces are discussed briefly. There is a wide scope for the better grading of road tars, for modification to render tar more nearly asphaltic and for the application of greater quantities in the use of tar in order to secure the best results with it. The common defects of asphaltic bitumen surfacing may possibly be remedied by blending with tar. The causes of all kinds of slipperiness should be studied.

E. G. R. ARDAGH

Commercial crushed stone. R. H. PIERCE. *Can. Dept. Mines, Mines Branch* No. 690, 36-58(1928).—Crushed stone quarries and their products from 64 Ontario and 7 Quebec localities are described, and the results of the usual tests of these products for road building material are tabulated. This paper informs the road builders of the 2 provinces of the location of suitable material. **Stone and its use in road construction.** *Ibid* 59-66.—The qualities which a road stone should possess and the interpretation of lab. tests are discussed. Trap rock, granites, quartzite, limestone and sand are described with reference to their utilization for road building.

L. W. R.

Road tar and its uses in Great Britain. W. E. COLE. *Chemistry and Industry* 47, 1048-54(1928).—Statistics for tar production in Britain, expenditures on highways, motor vehicles in operation and for mileage of tar macadam and surface tarring of existing roads are given. Criticisms of the application of tar to roads are dealt with. The following methods of using tar on roads are described: (1) tar spraying (hot surface dressing); (2) tar-macadam (surfacing); (3) grouted macadam (surfacing by penetration method); (4) tar emulsions (cold surface dressing and patching). Failures have been invariably due to one or more of the following causes: (1) inadequacy of foundation; (2) imperfections in the aggregates and poor grading; (3) inferior tar; (4) faulty construction. The advantages of tar are: (1) low initial cost; (2) minimum maintenance charges; (3) ease of application; (4) durability; (5) resilience; (6) permanent non-skid surface; (7) dustless and waterproof. These advantages are elaborated. British Road Tar Association's Specifications and the existing specifications of the Roads Department of the Ministry of Transport are given under the following heads: (1) general; (2) sp. gr.; (3) distn.; (4) detn. of tar acids; (5) detn. of naphthalene; (6) detn. of free C; (7) detn. of viscosity.

E. G. R. ARDAGH

Notes on road construction in Cork City. S. W. FARRINGTON. *Munic. Eng. Sanit. Record* 81, 545-6(1928).—F. discusses the different road-building materials. Steel tires and shoes constitute a high proportion of the traffic. Hills will be the most difficult problem in the future. C. H. BADGER

Slippery street paving. E. KINDSCHER AND O. SCHÖNEBERG. *Staatliches Materialprüfungsamt, Berlin-Dahlem. • Z. angew. Chem.* 41, 1048-52(1928).—Paving that has been washed thoroughly, as by prolonged rains, gives about the same friction to rubber tires as does dry paving, and the accidents that occur when a street becomes damp, or at the beginning of a gentle rain, are to be ascribed not to moisture as such, but to the slimy, slippery mass formed by the dirt already present on the street mixing with the water. The coeff. of friction on dry macadam (0.67) and asphalt (0.715) sinks to 0.17 or even 0.06 on such slippery paving. Samples of paving dirt were collected from 9 Berlin streets, and then examd. by phys. and chem. means. In 8 cases the total material collected varied from 0.7 to 3.2 g./sq. m. (on asphalt and wood-paved streets), and the 9th showed 15.8 g./sq. m. (on a stone-paved street). H_2O -sol. portions of the above amount to 10-20% of the total dirt. Seven of the residues had the odor of automobile exhaust gases, and the remaining 2 of fecal matter. H_2O -insol. dirt from asphalt streets showed about 30-40% content of material that came from the paving itself, i. e., worn out from it by traffic; it included 20-25% Fe-oxide, sand and clay, and the remainder contained the most varied materials, such as wool and leather residues, mineral oils and bitumen. The last 2 mentioned evidently hold the exhaust gases in soln. The H_2O -sol. materials resemble animal glues, and are high in N. No rubber was found in any of the samples. Evidently the intimate mixt. of H_2O and mineral oil, dust and org. matter forms a kind of emulsion that acts as a lubricant. With the addn. of H_2O the emulsion thins out and is more easily forced aside by the tires, until at last it can be washed from the streets by the rain, or soft water, much more readily than it can by the relatively hard city water. This fact has been established by expt. also. Distd. H_2O cleansed the streets even better than rain, and a 3% soap soln. best of all. One and 0.5% solns. of soda gave good results, and 1% NaOH and Na silicate solns. also proved useful. W. C. EBAUGH

The Irish Free State road outlook. R. T. KERWAN. *Munic. Eng. Sanit. Record* 81, 544-5(1928).—K. discusses the past, present and future conditions of roads and the uses and amts. of funds (grants) for road building. C. H. BADGER

Acid-proof containers and concrete paint for chemical factories. CONSTANTIN REDZICH. *Apparatebau* 40, 243-4(1928).—Concrete painted with "Sika," a colloid soln. of light and heavy metals, is made proof against acids, oils, etc. It costs 0.8-1.0 M. per kg., and 10 kg. will mix 1 cu. m. of acid-proof concrete, or 6 sacks of cement. J. H. MOORE

Coal residues in concrete. Effect on steelwork (ANON.) 21. **The manufacture of rubber road blocks** (FOL, VAN HEURN) 30. **Rubber as a floor covering** (KIRKWOOD) 10. **Developments in the gypsum industry in British Columbia** (COLE) 8. **Asbestos industry in Canada [for use in shingles, mill boards and cement]** (FREEMAN) 8. **Limestones of the Timiskaming District** (GOUDGE) 8. **Electrical dust precipitation** (LEWIS) 1. **Waterproofing and coating wood** (Brit. 286,396) 18.

Cement product. RICHARD V. MATTISON (to Asbestos Shingle, Slate & Sheathing Co.). U. S. 1,687,681, Oct. 16. Film-like layers of hydraulic cement-like material hydrated with an excess of water are assocd. with intermediate film-like layers of hydraulic cement material hydrated with water taken up from the layers first mentioned; the layers are pressed and permitted to set together to form an integral rigid product. An app. is described.

Portland cement. WALTER A. SCHMIDT (to International Precipitation Co.). U. S. 1,688,882, Oct. 23. In the wet process of manuf. of portland cement, dust is recovered from the kiln gases, mixed separately with water and some time after the mixture introduced into the raw mix slurry.

Aluminous cement. FIRM OF G. POLYSIUS. Brit. 286,122, May 6, 1927. The raw materials are fed to a rotary kiln without preliminary grinding.

Calcium aluminate cement. EMILE M. ROCHE (to Urbain Bellony Voisin). U. S. 1,689,891, Oct. 30. A cement is formed by burning a mixt. comprising bauxite and one or other suitable calcareous material at a temp. of about 900-1000° for a long period (suitably about 9-12 hrs.).

Rotary kiln and furnace construction for burning cement, etc. JOHN H. BENTLEY. U. S. 1,690,048, Oct. 30.

Potassium chloride from cement kiln flue dust or similar materials. NORMAN M. McGRANE (to International Precipitation Co.). U. S. 1,688,873, Oct. 23. Dust from portland cement manuf. or like material contg. sulfates and chlorides of Na and K is leached with an aq. solvent at super-atm. temp. and the leaching operation is continued until the concn. of Na and of sulfate reach a max. and then decrease while the concns. of K and Cl continue to increase; the soln. formed is sepd. from solid material and is cooled to effect sepn. of KCl.

Concrete paving block with surface layers of rubber. EDWIN C. WALLACE. U. S. 1,689,415, Oct. 30. Structural features.

Pavement for tennis courts, etc., comprising graded sizes of blast-furnace slag and a binder of brick dust. GERARD J. EILERS. U. S. 1,690,059, Oct. 30.

Pavement. LESTER KIRSCHBRAUN. U. S. 1,690,020, Oct. 30. A concrete foundation is covered with an emulsified mixt. of bitumen in water contg. an inert emulsifying ingredient such as colloidal clay while the concrete base is still plastic, so that a unitary structure is formed.

Road-surfacing material. FREDERICK W. VALLE-JONES (to Box, Stockell & Co.). U. S. 1,688,511, Oct. 23. A coarse aggregate such as stone is heated and cleaned by use of steam and the heated aggregate is then mixed with a colloidal mixt. of bituminous material.

Material for road surfaces. SAM E. FINLEY. U. S. 1,689,123, Oct. 23. A road is covered with bituminous material of suitable consistency and mineral aggregate is added and kneaded with the bituminous material to effect thorough admixture and to unite the coating with the underlying material of the road.

Artificial stone, bricks, briquets, etc. A. R. DAVIES, W. K. HUGHES and A. G. MORGAN. Brit. 286,334, Nov. 1, 1926. In making bricks, fuel briquets, etc., lime is used as a binder with gravel, sand, coal or other materials and is treated with CO₂ during slaking and the material or molded product is subjected to steam heat. An app. is described.

Material resembling marble. VINCENT MOLINARI. Fr. 636,140, Oct. 8, 1926. A material resembling marble is obtained by drying stone such as gypsum or alabaster in a furnace, plunging it successively into a bath of alum, a bath of K₂SO₄ and a coloring bath. The product is dried and polished.

Roofing. HENRY R. WARDELL (to Johns-Manville, Inc.). U. S. 1,689,985, Oct. 30. A sheet formed of cattle hair and asbestos fiber mixed and impregnated with asphaltic compn. is covered with a layer of adhesive asphalt and with an adherent surface layer of grit.

Laminated sheet roofing. WILLIAM R. SEIGLE (to Johns-Manville, Inc.). U. S. 1,690,079, Oct. 30. Felt sheets are used contg. a large proportion of asbestos and a smaller proportion of stiff hair-like material such as hair of cattle interspersed with the asbestos, impregnated with asphalt.

Expansion joint. ALBERT C. FISCHER. U. S. 1,689,945, Oct. 30. An expansion joint for use with concrete construction comprises over 60% of a ductile, compressible binder such as asphalt together with long animal hair and vegetable fiber such as excelsior, hemp and roofing scrap.

Bituminous mastic. CHARLES N. FORREST, JOHN S. MILLER, JR., and CHARLES S. BABB (to Barber Asphalt Co.). U. S. 1,688,041, Oct. 16. A compn. suitable for floors, walks or light driveways comprises mineral aggregate (the grains of which are between the limits of 8- and 60-mesh screens) 84-85, bitumen 14-16 and fibrous flock 0.6-0.7%.

Articles such as plaster board formed of calcined gypsum and fibrous material. WILLIAM H. KOBBE (to Texas Gulf Sulphur Co.). U. S. 1,689,394, Oct. 30. A sheet formed of cotton flannel, felt, jute or other suitable fibrous material and wet calcined gypsum is shaped before setting occurs and after setting the material is dried at a temp. above that at which calcination of the gypsum beings; the dried article is impregnated with S.

Treating waste carbide sludge from acetylene plants. DOUGLAS M. HARRISON (to McKenzie Mortar Co.). U. S. 1,688,542, Oct. 23. CaCl₂ is added to the sludge and the mixt. is heated and allowed to sep. into strata, the upper of which when sepd. is suitable for use as a plaster or stucco material.

Seasoning wood. FORREST S. SHINN. U. S. 1,687,000, Oct. 18. Wood is first subjected to steam and vacuum treatments, then to air pressure considerably higher than atm. pressure, followed by quick release to atm. pressure, and is then again subjected to steam and vacuum treatments.

Impregnating wood. J. T. HUGHES-JONES. Brit. 285,699, May 18, 1927. Oils

naturally contg. S such as shale oils are used for impregnating timber, with or without a polymerizations-accelerator such as resinate of Mn, Ni or Co or an oxide of Pb. The oil may be emulsified with glue from marine animals.

System for drying lumber, etc., in circulating heated air. HENRY C. BABEL (to Myrtle L. Babel). U. S. 1,687,822, Oct. 16. A drying kiln construction is described.

Substitute for lumber. WM. H. DROEGE. U. S. 1,688,138, Oct. 16. Artificial planks suitable for use at railroad and highway crossings are formed of bitumen 8-11, stone dust 16-25, finely divided gravel 54-71 and powd. Fe 5-10%.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

The training of fuel technologists. J. W. COBB. *Gas J.* 184, 135-7(1928).—A general discussion. F. S. GRANGER

Analyses of solid fuels. J. H. H. NICOLLS. *Can. Dept. Mines, Mines Branch No. 689*, 61-85(1928); cf. *C. A.* 22, 310.—The results of analyses of 155 samples of Canadian coals and of 51 samples including coke, U. S. coals, peat briquets, etc., are tabulated.

L. W. RIGGS

The examination of motor fuels by determining the boiling range. WAWRZINIOK. *Auto-Technik* 16, No. 19, 21 6; *Chem. Zentr.* 1927, II, 2254.—For detg. the boiling curve of motor fuels, W. uses a fractionating flask of 750 cc. vol. The width of the outlet tube of the flask is 0.75 of that of the neck. This arrangement helps to avoid any resistance in flowing. The flask, filled with 250 cc. of the fuel, sits in a sector 11 cm. in diameter of an asbestos ring, which is fastened to the top of a Babo plate and heated by a multiple burner. The boiling starts at a lower temp. with this equipment than with the Engler or Spilker-Kramer flask. The "dew point," where mist begins to form, is to be noted, because from this information, conclusions concerning the easy start of the motor may be drawn.

G. SCHWOCH

Commercial motor vehicles and their fuels. E. S. S. SMITH. *Petroleum Times* 20, 20(1928).—Low-temp. carbonization oils would find a ready use in the motor fuel field if they could be fractionated so that uniform fuels were obtained. If fuels with low "spirit" content, having 15-20% over at 100° and a 230-240° E. P., could be used in engines, such fuels could be had in plenty and might serve to stabilize the price of motor fuel.

M. B. HART

Recent developments in motor fuels from coal. A. C. FIELDNER. *Chem. Markets* 23, 375-8(1928); cf. *C. A.* 22, 3513. E. H.

Lockwood's Clean Coal Process, Ltd. ANON. *Mining Journal* 163, 832-3(1928).—The Lockwood is a dry-cleaning process for coal less than 1½ in. in size. Coal passes from bunkers to a deck inclined at an angle to suit the particular coal. An oscillating motion throws the material against and between converging buffers, which forces the particles into narrower but deeper masses which are aerated. The mass is then divided by an adjustable horizontal diaphragm, the clean coal passing over the top and the part of higher gravity dropping to a second stage of treatment. This treatment depends on the difference in resiliency between the coal and foreign particles. The tails from the first treatment fall on a quickly oscillating inclined surface and are impelled against an obstruction or barrier in such a manner as to cause them to rebound rapidly. The magnitude of the rebound varies with the density and allows the sepn. of the coal from the bone. The standard deck is 16 in. by 7 ft.; a unit consists of 8 or more decks for coarse and an equal no. for fines. Each deck has a capacity of 12-13 cwt. per hr. Power costs are low (1 h. p./unit). Five units (200 tons/day) can be run by a man and boy.

ALDEN H. EMERY

Nature of sulfur in Canadian coal and coke. J. H. H. NICOLLS. *Can. Dept. Mines, Mines Branch No. 689*, 34-50(1928); cf. *C. A.* 19, 1936.—Typical western Canadian coking coals generally contained but little S. Cokes from the Maritime Provinces coals, with the exception of that from Springhill coal, were too high in their S content to be used for metallurgical work. Cokes from Minto coal contained 4 or 5% of S, but much of this S could be washed out with steam. The analytical results of this study are assembled in 9 tables.

L. W. RIGGS

Instructions for burning coal, coke and peat. E. S. MALLOCH AND C. E. BALTZER. *Can. Dept. Mines, Mines Branch No. 689*, 6-11(1928); cf. *C. A.* 22, 310.—Detailed directions for burning American anthracite, Welsh and Scotch anthracite, semi-bituminous, bituminous, and Alberta coals, coke, mixts. of coal and coke and peat in hot air or hot water heaters are given.

L. W. RIGGS

The technic and economy of coal-dust firing. WM. GUMZ. *Brennstoff u. Wärme-wirtschaft* 10, 337-50(1928).—A discourse with numerous illustrations. F. S. G.

Machine for charging retorts with aspiration of dust. M. H. DÜTSCH. *J. usines gaz* 52, 414-5; *Monats. Bull. Schweiz. Ver. Gas. u. Wasserfach*, 8, (July, 1928).—The machine described is in operation in the gas-works of Flawil, Switz., and was built by the firm of Louis Giroud of Olten. One machine, mounted for vertical, forward and lateral movement on a traveling crane, serves a battery of retorts in charging and discharging. It is operated by motors but the charging hopper is fed by hand. The machine consists essentially of a rotary blower connected with 2 horizontal concentric tubes. In charging, the powd. coal is blown through the inner tube into the retort, while the gases escaping from the retort are sucked through the annular space, between the tubes, into the blower and cycled back with the charge. In discharging, the pair of tubes is thrust forward, by the movement of the whole machine, through the retort, to which it is fitted with a tight joint, pushing the coke out of the other end. Rapid service and complete suppression of fumes, flame and dust in the furnace room during charging are thus realized. F. S. GRANGER

Low-temperature carbonization. DAVID MUIR. *Gas J.* 184, 30-4; *Gas World* 89, 322-5(1928).—The performance of the *Illingsworth Process* at the Treforest Gas-Works is described. The special feature is in the construction of the vertical retorts of a no. of heavy cast-iron sections, functioning as heat conductors, permitting rapid and uniform carbonization at 600-620° with an outside temp. of 650-700°. Swelling is prevented by mixing coking coal with non-coking coal, coke breeze, etc., and by preheating. The finished semi-coke is dropped into a drum where it is mixed, by rotation, with wet-washed raw-coal smalls. The coke quenching is thus attained without addn. of water and utilized in drying the raw coal. This results in a satisfactory blended domestic fuel, 8% volatile, called *Ricoal*, for which a ready market has been found, and only 7% of breeze. A ton of dry coal yields 5900 cu. ft. of 680 B. t. u. gas, 8 lbs. $(\text{NH}_4)_2\text{SO}_4$, 4 gals. "benzole," and 17.5 gals. of crude tar contg. 30% phenols and leaving only 20% pitch on distn. The complete balance sheet shows a net profit of 6s. 2d. under existing economic conditions, per ton of wet coal. F. S. G.

Low-temperature carbonization—continuation of tests on Canadian bituminous coals. R. A. STRONG. *Can. Dept. Mines, Mines Branch No. 689*, 12 33(1928), cf. *C. A.* 20, 2405; 22, 311.—In the 10 coals tested, which were all of the coking variety, the volatile matter was 19 to 37%, coke 1500 to 1700 lbs. per ton, gas 3300 to 4000 cu. ft. and tar oil 7.5 to 22.5 Imp. gal. The numerical results are shown in 24 tables. Each of these coals proved good coke producers, but with one exception they are not suitable for low-temp. carbonization on account of low tar-oil and gas yields. L. W. R.

Combined low-temperature carbonization and combustion. D. BROWNIE. *World Power* 8, 301-9(1927).—With condensing steam turbine, the thermal efficiency from coal to switchboard is between 27½ and 32½%. The serious defects in present power station practice are (1) loss in cooling water of condenser (55-60% of total heat in coal) and (2) failure to adapt scientific methods of combining combustion with low-temp. carbonization. Two methods of low-temp. carbonization in the boiler house of the power station are discussed. With av. bituminous coal the yield per ton is 3500-4000 cu. ft. gas (750-850 B. t. u.) and 3500-3800 cu. ft. of combustion products. The final mixed gas of 7000-7800 cu. ft. per ton yields about 400 B. t. u. per cu. ft. Various processes of low-temp. carbonization are discussed in detail. A. D. S.

Coal residues in concrete. Effect on steelwork. ANON. *Gas J.* 184, 183(1928).—The joint committee of societies connected with the building industry attributes the detrimental effects, frequently observed following the use of cinders, etc., as aggregates in concrete in contact with steel, to expansion, high permeability to air and moisture, and the corrosive action of S compds. F. S. GRANGER

A disability of the ascension pipe. Its effect on undesirable fluctuations of calorific value. H. J. TOOGOOD. *Gas J.* 184, 407(1928).—In the early stages of carbonization, the ascension pipe is comparatively cool and is fed by a large supply of heavy gas. Hence its chimney effect is at a min. when it should be at a max. in order to avoid prolonged exposure of the rich gases to destructive heat, leakage, etc. In the later stages, the reverse is true and the calorific value is reduced by leakage inward. The remedy is suggested of mixing the gases before instead of after ascension, by connecting retorts horizontally in pairs with 1 ascension pipe, and charging the 2 retorts alternately. F. S. GRANGER

Recent methods for calculating on a technical basis the firing in steam boiler operation. KARL D'HUART. *Kautschuk* 4, 151-6(1928).—A review and discussion, with original references and representative data and calcns. C. C. DAVIS

Waste heat recovery. F. J. BAILEY, W. GREGSON AND J. W. REBER. *Gas J.* 184, 130-1; *Gas World* 89, 319-20(1928).—A general discussion covering *recuperators, regenerators, methods of air preheating, carbonizing plants, gas engines and waste heat boiler practice.* F. S. GRANGER

Air drying of Canadian lignite, and the reabsorption of moisture by the same. J. H. H. NICOLLS. *Can. Dept. Mines, Mines Branch* No. 689, 51-60(1928).—Dried lignite will not in any case reabsorb as much moisture as is contained in the corresponding air-dried coal. The less severe the method of drying employed, the more moisture the lignite will reabsorb; conversely the more severe the drying, the less moisture the lignite will reabsorb. Of 2 samples dried rapidly under similar conditions, the one with the lower moisture content will reabsorb moisture the more rapidly at first. The addn. of water to lignite, either raw or dried, previous to exposure to the air-drying atm., does not alter the relation between the air-drying and moisture reabsorption curves. The most satisfactory relative humidity for air drying was 60%. Analysis of ground coals should not be delayed, particularly in winter. L. W. RIGGS

The behavior of the sulfur in brown coal on dry distillation. HORST BRÜCKNER. *Braunkohle* 27, 891-3(1928).—The percentages of each of the different forms of S, before and after carbonization, were compared in 9 specimens. Sulfate, sulfide and pyrite S were detd. directly and org. S was detd. by difference. Generally more than half of the total S was lost on carbonization, presumably as H_2S . This seems to take place at a lower temp. than with ordinary bituminous coal. All forms lost more or less. Pyrite S suffered the heaviest loss, apparently being converted into org. S in the coke, the reverse of the geological process. The sulfates were believed to be converted into sulfides which were in turn converted into H_2S by the action of CO_2 , etc. F. S. GRANGER

The chemical analysis and evaluation of gasoline and benzene motor fuels. ROBT. KATTWINKEL. *Teer u. Bitumen* 26, 481-5, 501-4(1928).—A comprehensive review and literature survey covering phys. properties and hydrocarbon groups. F. S. G.

The Hamburg gas works and the present problems of the German gas industry. H. MÜLLER. *Gas u. Wasserfach* 71, 841-7, 868-72(1928).—Rates, transmission, by-products, super-gas system competition and other problems of the German gas industry are discussed. R. W. RYAN

Manufacture of producer gas. J. V. POSTLES. *Ceramic Age* 11, 135-7(1928).—A description of the manuf. and use of producer gas. W. H. RISING

Blue and carburetted blue gas. CARL A. SCHLEGEL. *Ceramic Age* 11, 85-8(1928).—A discussion of the principles involved and app. used, as well as characteristics of these types of fuels. W. H. RISING

Coal and coke-oven gas. F. C. WEBER. *Ceramic Age* 11, 20-1(1928).—Coal and coke-oven gas are essentially the same and are made by destructive distn. of coal. Gas-coal should have good coking properties and low ash content although sometimes good results are obtained with ash as high as 15%. By-products are 1400 lb. of coke, 10-12 gal. of tar, and 20-30 lb. of $(NH_4)_2SO_4$ per ton. Distn. is carried out in a refractory chamber heated to 2000-2500° F. and yields about 11,000 cu. ft. of 550 B. t. u. gas per short ton. Silica brick lasts 3-4 times as long as clay brick for lining. The coking chambers or slots are arranged in batteries and are charged and emptied mechanically. The batteries are fired from below, usually with the gas manufactured. The gas collects in a main above the batteries and is conducted through a scrubber to a

storage tank. Coke ovens are usually owned by steel mills which use the coke but are coming more into domestic use both for the gas and coke. W. H. RISING

The chemico-physical fundamentals of tar gas purification. G. JUNGE. *Teer u. Bitumen* 26, 465-9(1928).—A review of the difficulties existing in the removal of tar from coal gas, their causes and the possible means available for overcoming them.

F. S. GRANGER

Fluid-tight ferroconcrete gas purifiers. P. N. ROY. *Gas J.* 184, 274; *Structural Engineer* (Oct., 1928).—B. N. Dey has shown the importance of correct incorporation of reinforcements, grading of aggregate and proportions of concrete mixt. and of the use of large panels of thick slab, as opposed to surface dressings which are merely palliatives. Such tanks are proving satisfactory in use.

F. S. GRANGER

Aspirating gas producer. Otto system. ANON. *J. usines gaz* 52, 415-6; *Génie Civil* (Aug. 4, 1928).—Among the outstanding features is the generation of the steam required, partly by a boiler incorporated in the dome and utilizing the waste heat in the generated gas, and partly by a trough around the rim of the circular grate into which water is introduced. The introduction of the steam from the boiler into the space below the grate is regulated, to meet requirements, by an automatic valve, any excess being allowed to blow away. The air is preheated by being drawn in through an annular space between the outer sheet iron shell of the body of the generator and the refractory lining. The feed hopper is provided with gas-tight top and bottom covers to permit introduction of charge without admission of air. The arrangement of the hearth permits the continuous flow of coal and ashes without clogging.

The influence of temperature on the flame velocity of gases. K. BUNTE AND A. STRÖDING. *Gas J.* 183, 596-8, 650-2; 184, 31-5(1928).—Translation of an article appearing in *C. A.* 22, 3977.

F. S. GRANGER

Technical control in the retort house. RONALD B. GLOVER. *Gas J.* 184, 203-5 (1928).—A general discussion relating mainly to control of gas quality and the recording of materials charged and other details in gas plant operation.

F. S. GRANGER

Some aspects of ammonia recovery from steamed vertical retort gas. C. SINGLETON AND J. E. STANIER. *Gas J.* 184, 405-7(1928).—The full utilization of the water contained in the retort gases, for the NH_3 absorption, by efficient counter-current recirculation under pressure, to cut down the vol. and increase the concn. of the virgin liquor, is suggested. Less virgin liquor would also mean less phenols in the effluent liquor, but this should be further avoided by sepg. the tar above the dew point of the gas, since NH_3 increases the soly. of phenols in water. Only 7.7% of the H₂S in the gas is removed during condensation and washing. The quantity of chlorides found in the virgin liquor exceeds that of the sol. chlorides found in the coal carbonized. This is attributed not to org. chlorides but to inaccuracy of the hot-water washing method of detg. sol. chlorides in coals. The recovery of NH_4Cl and other questions are discussed. The practice at the Stockport Gas Works is described.

F. S. G.

A tar obtained from brown coal by steam distillation. II. Comparative experiments on the neutral constituents of a steam tar and of a tar produced by external heating. W. FISCHER. *Inst. Ges. Braunkohlen u. Mineraloelforschung Tech. Hochschule, Berlin. Braunkohle* 27, 925-9, 951-6(1928); cf. *C. A.* 21, 4051. —Since bitumen distils largely undecompd., it was first extd. by benzene + alc. Two samples of the debittumenized coal were then distd. (1) heating internally with superheated steam to 460°, in about 10 hrs., holding at various temps. until no more tar came over and (2) heating externally to 500° in about 5 hrs. The extd. bitumen was also dry distd., like (2), to 525°, furnishing a 3rd tar (3). The tars obtained were vacuum distd., freed from paraffin wax, tar acids and bases by the usual methods, and from O compds. by shaking with acid ferrocyanide soln., and finally fractionated in vacuum over Na. This last treatment was found necessary for the subsequent crystn. of picrates. Fractions 120-130°, 130-140° and 160-170°, at 10 mm., were investigated. The *picrates* of the *naphthalene-type aromatics* were obtained by treatment with hot satd. alc. picric acid soln. and allowing to crystallize, and analyzed, etc. A second sample of each fraction was *dehydrogenated*, by heating under reflux for 6 hrs. with 0.4 part of S, according to Ruzicka, to a gradually approached oil bath temp. of 240°, and then distd. in vacuum over Na and treated with picric acid, as above, to obtain the *hydroaromatics* by difference. The 120-130° fractions from tars (1), (2) and (3) yielded, resp., 0, 3.6 and 1.78% *naphthalene-type aromatics* and 5.25, 5.47 and 1.94% *hydroaromatics*, the 130-140° fractions, 0, 4.26 and 2.13% and 3.33, 14.22 and 7.44% and the 160-170° fractions 0.2, 8.91 and 1.35% and 1.51, 8.02 and 4.65%, after correcting for the usual assumed loss of 25% of these hydrocarbons during dehydrogenation. These results are attributed to secondary decompn. due to local overheating in the

externally heated cases. The picrates gave sharp m. ps., and those from corresponding fractions were found identical, by the mixed m. p. method, from the 3 tars and before and after dehydrogenation, except that from the highest fraction of the steam tar, m. 152° and corresponding to a hydrocarbon, $C_{14}H_{18}$. The quantity was too small for further identification. The same fraction from the other tars also yielded a $C_{14}H_{18}$ picrate but it m. 138-9°, corresponding to a hydrocarbon isolated by Tammann from Russian petroleum, which he characterized as a tetramethylnaphthalene. The others were $C_{14}H_{18}$ picrate, m. 112°, from the first fraction, and $C_{13}H_{14}$ picrate, m. 123°, from the second, corresponding to Herzenberg and Ruhemann's 1,3 or 2,4 methylisopropyl-naphthalene and α -isopropyl-naphthalene, resp. Cf. C. A. 21, 2122. F. S. G.

The Kraemer-Sarnow method and the toxicity of mercury. LUDWIG MILLBRADT. Büsscher & Hoffmann A. G., Eberswalde. *Teer u. Bitumen* 26, 485-6(1928).—The following method is employed in the lab. of the above company to minimize the now well-recognized danger of Hg poisoning from continual exposure to minute quantities of Hg vapor in the manipulation of the Kraemer-Sarnow method for detg. the softening point of pitches, which it is not desirable to abandon because of certain advantages over other methods. The stem of a funnel is cut off at right angles and attached to another glass tube by means of a rubber tube contg. a glass bead, flush with both tubes. The stem is marked to indicate the level of 5 g. of Hg. It is then inserted into a bottle, by means of a stopper above the rubber tube, and Hg is poured in to above the mark and then run out to the mark, lifting the funnel out of the bottle just far enough to manipulate the rubber tube. The 5 g. dose is then run into the melting tube for the test. The funnel is kept covered by an etched glass plate sealed with grease.

F. S. GRANGER

The effect of coal segregation, mixing and heating upon the quality of metallurgical coke. F. F. MARQUARD. *Blast Furnace & Steel Plant* 16, 754-7, 914-6(1928).—The Clairton, Pa., plant of the Carnegie Steel Co., employs 100% high-volatile Pittsburgh coals in making by-product coke. The coal is coarsely prep'd.; a typical sieve test is 7.1% on 2 in., 19.6% on 1 in., 19.5% on $\frac{1}{2}$ in., 16.8% on $\frac{1}{4}$ in., 14.0% on $\frac{1}{8}$ in. and 23.0% through $\frac{1}{8}$ in. Coal of this size weighs about 51 lbs. per cu. ft. while coal crushed so that 80% passes through $\frac{1}{8}$ in. screen weighs only 48 lbs. per cu. ft. Slate is removed from coal to improve its coking quality and lower the ash content of coke. Compartment-type bunkers prevent segregation of coarse and fines in travel of coal. Each bunker has a capacity of 5000 tons and contains 24 compartments. Coking temps. of 2075° F. and more are always maintained.

D. GORDON

The reactivity of coke. F. J. DENT. Leeds Univ. *Gas J.* 184, 199-200(1928).—Expts. by the Gas Investigating Comm. are reviewed. A max. reactivity with steam at 1100° was shown by coke prep'd. at 800° as against 500° and 1100°. Coke prep'd. in the lab. from coal + 8.5% Na_2CO_3 showed, with steam, about double and, with CO_2 , about 10 times the reactivity of com. cokes. Reactivity with dil. O_2 showed a decided variation between different cokes up to 700° above which all burned at the same rate, supporting the view of Haslam that, at high temps., combustion is so rapid that its rate depends only on the rate at which O_2 is brought into contact with the C. In deep beds, however, it was shown that more reactive cokes developed lower temps. because of the endothermic reduction of CO_2 to CO. The *ignition temps. of cokes* decreased with the temps. at which they were prep'd. Considering the results reviewed, the relation of reactivity to practical application was then discussed. Because of the high temp. required, it follows that a less reactive coke is more suitable for the *foundry cupola*. In the *blast furnace* a coke of low reactivity furnishes sufficient CO for the reduction of the ore and is therefore preferred because of the high temp. required for melting down the metal. In the *gas producer*, high reactivity is obviously preferable, especially as the lower temp. decreases clinkering. In the *water-gas plant*, high reactivity would be advantageous in the run period and low reactivity in the blow period. In the *Dellwicks-Fleischer method*, in which it is sought to solve this dilemma by a thin bed of highly reactive coke, it is found that the saving is more than counterbalanced by increased sensible heat losses in the blow gases, less steam decompd., increased power consumption and lower output. The CO burns to a large extent above instead of in the fuel bed. This heat is therefore not available for the run period. It is therefore found better to use a deeper bed and utilize the CO, produced during the blow, by burning it to heat the waste-heat boilers, etc. Hodsman and Dyde, at Leeds, Univ., measured the heat radiated by various cokes in *domestic grates*. More reactive cokes showed less efficiency, since CO burned above the fire, giving lower heat concn. Low-temp. cokes are superior because of ease of ignition and less attention required. Also in *Gas World* 89, 435-6(1928).

BEAUFAX, G. *Bilans thermiques.* Charleroi: Librairie de la Bourse J. Wattiaux. 300 pp.; F. 37.20. Reviewed in *Chimie et industrie* 20, 403(1928).

Fuel. HERBERT E. WETHERBEE (one-third each to Richard F. Grant and Howard M. Hanna). U. S. 1,687,815, Oct. 16. Before coalescing particles of fuel such as coal or lignite the material is preliminarily treated while in moistened condition with a filming carrier such as linseed oil and a binding material such as dextrin so that the latter is evenly applied to the fuel particles. An app. is described.

Motor fuel. SOCIÉTÉ DES BREVETS ÉTRANGERS LEFRANC ET CIE. Fr. 637,993, Nov. 30, 1926. A motor fuel consists of equal parts of complex ketones from the dry distn. of aliphatic Ca salts such as Ca butyrate, and MeOH or benzene. To increase the calorific value heavy hydrocarbons such as naphthalene may be added. The ketones are preferably those which distil between 60 and 140°. Cf. C. A. 22, 1461.

Atomization of liquid fuel. RUDOLF AUERBACH. Fr. 638,314, July 27, 1927. Liquid fuel for Diesel or other motors is atomized by a direct or induced elec. charge, either alone or with mech. atomization.

Electric control system for liquid fuel burners. ROBERT F. METCALFE (to Socony Burner Corp.). U. S. 1,688,126, Oct. 16.

Carbonizing fuel. H. M. RIDGE. Brit. 286,104, Aug. 23, 1926. Fuel is distd in passing through a superposed hearth oven (which is described) and the coke residue passes over a cooling hearth and after discharge from this is immediately briquetted.

Distilling powdered fuel. KOHLENVEREDLUNG A.-G. Brit. 286,404, Dec. 31, 1926. In low-temp. distn. of powd. or granular fuel which passes through the distn. chamber in suspension in a gas, hot producer or water gas is used immediately after leaving the gas producer and is fed into the distg. chamber together with the powd. fuel through a common nozzle. An app. is described.

Low-temperature distillation [of solid fuels]. COMPAGNIE DES MINES DE BRUAY. Fr. 638,335, July 27, 1927. A furnace for the continuous low-temp. distn. of all solid fuels consists in several vertical cells which are heated by gases circulating in their walls.

Vertical furnace for distillation and gasification of solid fuel. PIERRE EUGÈNE HENRI FORSANS. Fr. 637,906, Nov. 20, 1926.

Fuel mixture comprising coal dispersed in oil, etc. A. W. BURWELL (to Alox Chemical Corp.). Brit. 286,260, March 2, 1927. Finely divided coal or other solid fuel is dispersed in a gel produced by dissolving in petroleum fuel oil an alkali metal salt of a saponifiable acidic material obtained by the controlled oxidation of a liquid aliphatic hydrocarbon. Details are given for producing products which may be pumped.

Destructive hydrogenation. M. MELAMID. Brit. 285,879, Feb. 24, 1927. Liquid products are prepd. from carbonaceous material, oils, tars, etc., by spraying the material intimately mixed with a catalyst (which may be a finely divided metal, alloy or metal oxide) into a heated retort under pressure by a current of H or gases contg. H.

Destructive hydrogenation. I. G. FARBENIND. A.-G. Brit. 285,923, Sept. 10, 1925. Destructive hydrogenation of carbonaceous materials is effected under pressures of at least 50 atm. in the presence of catalysts such as alumina, thoria or other rare earths or oxides or carbonates of V, alone or mixed or with the addn. of Fe or

other metals of the 8th group or compds. of such metals. H itself may be used or H_2S , or other reducing gas contg. H, such as water gas or mixts. of H with N, H_2O vapor or CH_4 , etc., may be used. An example is given of the treatment of brown coal producer tar to obtain a yield of 50% of "petrol."

Hydrogenation of coal, etc. I. G. FARBENIND., A.-G. Fr. 638,325, July 27, 1927. In the hydrogenation of coal, tar, mineral oils, etc., the heat necessary for the reaction is obtained by passing a heated gas, taking part in the reaction or not, through the contact chamber. Preferably the H itself is heated.

Flotation separation of coal from clay or other impurities. CHEMISCHE FABRIK IN BILLWÄRDER VORM. HELL & STRAMER A.-G. AND F. L. KÜHLWEIN. Brit. 286,456, March 5, 1927. Impure coal, coal sludge or coal-contg. residues are purified by use of weak alk. or alk. earth solns. of xanthates as frothing or flotation agents. An app. is described.

Treating coal with coloring matter. GUSTAVUS J. ESSELEN, JR. and MARK W. WEISS (to Delaware, Lackawanna & Western Coal Co.). U. S. 1,688,695, Oct. 23. Coal, the pieces of which have an irregular surface with crests and valleys, is provided with coloring material such as ultramarine which is deposited in the valleys of the surface and serves as an identification of the brand or source of the coal.

Apparatus (with vertical retort) for distilling coal and similar materials. CHARLES H. PARKER. U. S. 1,689,152, Oct. 23.

Collecting pipes for coal distillation retorts. LOW TEMPERATURE CARBONISATION, LTD. Fr. 636,459, June 22, 1927.

Retort (formed with connected tubular sections set in downward inclination) for distillation of coal, etc. CHARLES H. PARKER. U. S. 1,687,990, Oct. 16. U. S. 1,687,991 also relates to somewhat similar app. for the same purpose.

Retort construction (with a battery of vertical retorts) for coal distillation, etc. CHARLES H. PARKER. U. S. 1,687,989, Oct. 16.

Apparatus for evacuating residues from retorts in the distillation of coal, etc. LOW TEMPERATURE CARBONISATION, LTD. Fr. 636,458, June 22, 1927.

Fuel gas. ALFRED H. WHITE. U. S. 1,689,940, Oct. 30. In a continuous process of manuf. of gas with a heating value of over 200 B. t. u. per cu. ft., a charge of solid fuel such as coke or coal within a gas generator is continuously blown with a gas mixt., the main reactive constituents of which are O and steam, in such proportions and quantity that the fuel bed is maintained at a temp. of at least redness and the hot gases form gaseous hydrocarbons with enriching carbonaceous material such as petroleum oil which is introduced and reacts with the gases while also undergoing destructive distn. out of contact with metal surfaces and at slowly decreasing temps. maintained principally by the reactions in the generator. Deposition of free C is largely avoided. An app. is described.

Drying fuel gases. C. COOPER AND W. C. HOLMES & Co., LTD. Brit. 285,936, Oct. 21, 1926. Fuel gases passing through a main are by-passed through brush-washers in which they are treated with hygroscopic liquid and the liquid is cooled and regenerated by circulation through independent circuits connected to the washers. The app. is described in detail.

Treating gas liquors. FÉLIX SCHÖNFELD. Fr. 638,035, July 20, 1927. Gas liquors are treated with S or sulfides, in the presence of catalysts such as active C, silicic acid or wood charcoal, to convert the cyanides into non-volatile thiocyanates and distd.

Gas producer. PAUL BEAUDEQUIN. Fr. 638,529, Dec. 7, 1926. The hearth of a gas producer terminates in a conical-shaped ring which can be rotated to empty the cinders or ashes.

Gas-producing apparatus and screw device for feeding fuel to same. WILBUR L. SHEPARD (one-half to Edward A. Beals). U. S. 1,689,159, Oct. 23.

Gas retort and regenerator construction. R. W. BROADHEAD. Brit. 286,418, Jan. 17, 1927.

Gas burner for tangential feed tubes. BADER & SALAU. Fr. 636,455, June 22, 1927.

Rich gas and semi-coke from bituminous fuel. METALLBANK UND METALLURGISCHES GES. A.-G. Brit. 285,664, March 15, 1927. In producing rich gas, semi-coke and NH_3 from bituminous fuel, by use of O or gases rich in O, with or without steam or CO_2 , the upper zone of the fuel column is distd. by gas obtained by gasification of fuel in the lower zone and the lower zone is divided into 2 parts, one of which is subjected to gasification by the O or gases rich in O while the charge in the other portion of the lower zone is withdrawn as semi-coke. Tar residues or similar material may be

injected into the hot zone and the steam may be admitted preferably through the hot semi-coke to serve for quenching the latter.

Control system for valves of water-gas plants, etc. POWER-GAS CORPORATION, LTD., N. E. RAMBUSH AND C. S. D. HARPER. Brit. 285,996, Nov. 25, 1926. Various details of an elec. control system are described.

Extraction of phenols. F. RASCHIG. Fr. 636,301, Feb. 7, 1927. Phenols are extd. from ammoniacal liquors by means of benzene or its homologs in a column washer contg. Raschig rings having a diam. of 15 mm.

Distilling tar. S. P. MILLER (to Barrett Co.). Brit. 286,278, March 2, 1927. In distg. tar by contact with the hot gases from coal carbonization retorts, coke ovens or the like, the uptake pipes of a plurality of retorts are connected to one or more stills into which the tar is sprayed through nozzles. Various features of construction of the app. are described. Cf. C. A. 22, 4779.

Distilling tar. F. OSBORNE (to Barrett Co.). Brit. 285,907, Feb. 26, 1927. Gases and vapors produced by distg. tar by contact with part of the hot gases from a battery of coke ovens are mixed with the remaining gases which have been previously cooled to remove the heavy tar constituents, and the mixt. obtained is cooled to recover condensable constituents. An app. and various details are described.

Separating constituents of aqueous tar emulsions. BIGGER JOHNSON. U. S. 1,689,728, Oct. 30. An emulsion such as an aq. tar emulsion from gas works is mixed with a carboxy acid such as oleic acid which is substantially insol. in water but is sol. in the tar constituent of the emulsion and the emulsion is allowed to stand at an elevated temp. (suitably about 60-70°) until the water is sepd. from the tar.

Apparatus and circulation system for dehydrating tar. ARTHUR W. WARNER. U. S. 1,689,309, Oct. 30.

Coke-oven construction. DR. C. OTTO & Co., Ges. (to Naamlooze Vennootschap Silica en Ovenbouw Maatschappij). Brit. 286,234, Feb. 28, 1927. Rich gas is supplied to the heating flues through horizontal distributing conduits beneath the oven sole, in the operation of an oven such as that described in Brit. 240,167 (C. A. 20, 2244).

Removing graphite from coke furnaces. GEORGES CAPLAU, MICHEL GAUQUER and LOUIS LAHAUT. Fr. 638,439, July 29, 1927. Incrustations of graphite are removed from furnaces while still warm by a jet of compressed air carrying hard or granulated material.

Tank and associated apparatus for separating coke from clinkers or other granular materials of different specific gravities by use of liquids such as water. ANTHONY R. SILVERSTON (to Coke Reclamation Corp.). U. S. 1,689,536, Oct. 30.

The gasoline contg. some acid is treated with clay (3 lbs. per bbl.) in an agitator from which the gasoline-clay mixt. is withdrawn to a Sweetland filter for the removal of the clay. M. B. HART

The recovery of gasoline from field and refinery gases with special reference to the Bayer activated charcoal process. ION EDELEANU. *Chimie et industrie* 20, 429-40 (1928).—See C. A. 22, 3039. A. PAPINEAU-COUTURE

Applied gas and gasoline analyses. J. C. BURKS. O. C. Field Gasoline Co. *Oil & Gas J.* 27, No. 16, 142, 144, 146(1928).—The results of the cold fractionation of various samples of gasoline and gas to det. the hydrocarbon components are reported. From an analysis of various samples the efficiency of the fractionating column may be detd. by comparing the sum of the constituents with the constituents entering the plant. By plotting the analyses on a three-dimensional graph, the distn. recovery of a gasoline of a given percentage compn. of C_3H_8 , total C_4H_{10} , and C_5H_{12} plus, may be detd. if the distn. recovery lies between 78 and 95%. M. B. HART

Miscibility of castor oil with gasoline hydrocarbons. GEO. H. TABER AND DONALD R. STEVENS. *Ind. Eng. Chem.* 20, 1185-6(1928).—Expts. to det. the miscibility of

castor oil with petroleum naphtha indicate that the miscibility depends upon the character of the petroleum product used. The paraffin hydrocarbons used have a limited, though high, soly. in castor oil, while the olefins, naphthenes and aromatic hydrocarbons seem to be miscible in all proportions. D. F. BROWN

Gasoline capture by adsole. HAJIME ISOBE AND SHUTCHI MORI. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 683-730; English Ed, 1, 63-4(1928).—Wet gas is run through 3 towers contg. adsole [acid earth], and gasoline is recovered from the adsole by heating. Complete data are given for a set of runs. A. L. HENNE

Critical temperatures and oil cracking. RALPH H. MCKEE AND HAROLD H. PARKER. *Ind. Eng. Chem.* 20, 1169-72(1928).—Cracking stocks, such as gas oil, have definite critical temps. which may be calcd. from the av. boiling points by formulas given. These critical temps. are below the av. temp. of the oil leaving the heating tubes in some of the more important so-called liquid-phase cracking processes such as the Cross process and the "Tube and Tank" process. These processes are, therefore, really vapor phase processes. Asphaltic substances, the non-volatile in the ordinary sense of the word, are sol. in highly compressed vapors. D. F. BROWN

Cracking or hydrogenation. M. NAPHTALI. *Petroleum Z.* 24, 611-4, 658(1928).—A review of recent literature on the theory of cracking, with a brief description of various cracking and hydrogenation processes. Recent patents are also reviewed. M. B. HART

Catalysts in oil cracking. H. PINCASS. *Petroleum Times* 10, 1020 1(1928).—The outstanding patents relating to the use of catalysts in cracking are reviewed. M. B. HART

Volumetric and A. P. I. gravity changes due to the solution of gas in crude oils. R. VAN A. MILLS AND R. E. HEITHECKER. *Bur. Mines, Repts. of Investigations* No 2893, 15 pp.(1928).—The soly. of city gas (in Bartlesville, Okla.) in 3 different crude oils was detd. at 70° F. and at pressures from 200 to 1000 lbs. The crude oils ranged in gravity from 20.5 A. P. I. (60° F.) to 40.6. The results are presented in tabular and chart form and show that decided increases in vol. and in A. P. I. gravity of the oil are caused by the soln. of gas in oil under pressure. Decided decreases in vol. and gravity were noted with the liberation of gas from soln. and the diminution of gas pressures. D. F. BROWN

Storage and transportation of mineral oil. L. SINGER. *Petroleum Z.* 24, 373 6 (1928).—An amplified bibliography of articles on storage and transportation of oil during 1927. M. B. HART

Distillate as its own induction pump in continuous treating system. PAUL TRUESDELL. *Natl. Petroleum News* 20, No. 34, 65-6, 68(1928). A continuous treating system in which cracked distillate is treated with caustic, hypochlorite soln. and H₂O in turn. Vertical treating tanks are used and all mixing is done with Venturi mixers. M. B. HART

Analysis of Russian mineral oil products. JOHANN DIESTENFELD. *Kommerzial rat, Wien. Petroleum Z.* 24, 763-8(1928).—Analyses are given of benzine, ligroin, illuminating oils, spindle oil, machine oils, lubricating oils, miscellaneous oils, fuel oils, etc., having various trade names, as given by the "Grosneft, Asneft and Embanest". M. B. HART

Quick action reduces loss and coking when pipe-still tube fails. J. C. CHATFIELD. *Natl. Petroleum News* 20, No. 40, 61, 63(1928).—At the Okmulgee plant of the Barnsdall Refineries, Inc., the system of handling ruptured tubes in pipe stills consists in isolating a tube still from its crude supply and tower system and purging the tubes of oil under steam pressure. The distn. system designed by G. T. Granger flashes out the light fractions of crude in a sep. tower section before entering the pipe still. In the distn. system light vapors from the top tray of the 1st tower pass through the reflux condenser surmounting the tower and are charged into the 2nd tower over about the 7th tray. Gas oil withdrawn from the 3rd tray of the 1st column is pumped through the reboiler coil in the 2nd tower and through a cooler to storage. The temp. of the 2nd tower is maintained about 50° below the desired 90% point. Kerosene is withdrawn from the bottom of the 2nd tower, the outlet being extended down to a point below the reboiler coil through which hot gas oil is pumped. M. B. HART

Low humidity hastens bright stocks settling. L. C. JAMIESON. *Viking Oil Co. Natl. Petroleum News* 20, No. 39, 89-91(1928).—At the Viking Oil Co.'s wax plant 3000 barrel settlers size 25 by 30 ft. are most used, the cooling coils being placed in 2 planes, 1, 2 or 3 ft. from the top level, the second a few feet below the first. The use of steam pumps equipped with Mason governors for the filtered soln. and the benzine

provide for the regulation of gravity.* Low humidity hastens bright stocks settling.

New dehydration process and low-gravity oil topping unit. ANON. *Oil Age* 25, No. 6, 49, 54(1928).—The Merrill dehydration process is described.

M. B. H.

Three types of compression plants. C. O. WILLSON. *Oil & Gas J.* 27, No. 18, 130-1(1928).—Three main types of compression plant hook-ups are described. In the first, wet gas passes through a low-stage compressor and water condenser where heavy gasoline ends are condensed out and then to a high-stage compressor under 300 lbs. where the remaining gasoline is removed. The gasoline from both stages is combined and fractionated. In the second type, the gas is scrubbed before and after the low-stage compression, the gas from the high-compression stage being fractionated. The low-stage gasoline is ready for the market without further fractionation. C_2H_6 from the fractionator is recycled to the wells. In the third type, gas from the low-stage compressor is cooled and passed to the fractionator. Uncondensed gas from the latter is released to the high stage of the compressor from which it is passed to a condenser and accumulator tanks. Residue gas is released for well operation.

M. B. HART

Corrosion in refineries menaces profits, health and life; some suggestions. E. R. LEDERER. Texas Pacific Coal and Oil Co. *Natl. Petroleum News* 20, No. 40, 22-5 (1928).—The principal types of corrosion found in the refinery are (1) atm., (2) H_2O corrosion, (3) soil corrosion, (4) chem. corrosion. The palliatives suggested include for (1) the use of special paint and metal coatings, for (2) proper treatment of boiler feed water and the use of proper metal tubes, for (3) analyses of the soil and proper coatings for pipe, for (4) neutralizing charging stock with NH_3 , lime or soda, and inspection of materials.

M. B. HART

The solidifying point of paraffin-containing mineral oils and residues. A. N. SAKHANOV. *Petroleum Z.* 24, 654-5(1928).—The solidification points of various samples of Grosny crude and masut have been detd. The method used consisted in heating the sample in a tube having a diam. of 15-20 cm. for an hr. at various temps., and cooling to room temp. or below until solidification occurred. In cooling the tube was placed within a second tube about 4 mm. greater in diam. and the thermometer inserted in the space between. The following conclusions were drawn from the results: (1) The solidification point of paraffin-contg. crude oil and masut varies with the temp. to which it is heated; (2) the highest solidification point corresponds to a preheating temp. which varies with the oil but lies between 40 and 60° and increases with the paraffin content; (3) higher preheating temps. cause a depression of the solidification point, the depression disappearing on standing.

M. B. HART

Adopts Reid vapor pressure test. ANON. *Oil & Gas J.* 27, No. 15, 328(1928).—The Natural Gasoline Asscn. announces the adoption of the Reid vapor pressure testing method as a tentative standard effective Sept. 1, 1928.

M. B. HART

Various designs in pipe stills. D. G. BRANDT. Henry L. Doherty & Co. *Oil & Gas J.* 27, No. 19, 128(1928).—The present bubble cap tower is inefficient from a heat standpoint. The use of heat exchangers between each tray for the maintenance of the proper thermal gradient is more satisfactory. Side streams may be taken out and handled as in other towers except that kerosene is made as an overhead distd. product. At the H. L. Doherty Co. all tubes work at a moderate rate, the fire box temp. being regulated by the quantity of flue gas recirculated.

History and development of antidetonating agents for motor fuel. H. S. TEGNER. *Petroleum Times* 19, 749-51(1928).—A review.

M. B. HART

One method of extinguishing fires. C. A. THOMAS AND C. A. HOCHWALT. *Oil & Gas J.* 27, No. 14, 142(1928).—Alkali metal compds. have been shown to have a

catalytic effect in extinguishing oil fires. This effect increases with the increase in at. wt. of the metal and varies with the radical to which the metal is joined, O_2 -bearing radicals being most effective. Tables are given to show relative efficiency of various compds. of the alkali metals, and test methods are described. M. B. HART

Trend in antiknock motor fuels. GRAHAM EDGAR. Ethyl Gasoline Corp. *Oil & Gas J.* 27, No. 17, 97, 162, 164(1928).—The present status of knowledge of knocking characteristics of fuels and the elimination of knock is discussed. M. B. HART

Estimation of a possible coke formation in petroleum products. N. I. CHERNOZHUKOV. *Neftyanoe Khozyaistvo* 15, 69-72(1928).—C. compares the C detn. by Conradson with Butkov's method of testing oil under heat and pressure. The 2 tests give quite different results. An oil low in Conradson C can be high in C when both heat and pressure are applied, particularly when in the presence of O_2 . White oils and paraffin wax do not form coke. The detn. of excise resins and the color do not indicate a possible formation of coke. A. A. BOEHLINGK

Dehydration of bitumen emulsion from Alberta bituminous sands. P. V. ROSEWARNE and G. P. CONNELL. *Can. Dept. Mines, Mines Branch* No 689, 96-103(1928).—Water cannot be sepd. from bitumen by ordinary distn. methods because of excessive frothing. A special still is described whereby the wet bitumen is fed into a cylindrical retort, the bottom of which is covered with melted Pb, at a rate such that the water was entirely removed by the time the bitumen reached the outlet at the bottom of the still. The water vapor and some light oil passed from the top of the still to a condenser. Data of typical runs are given. L. W. RIGGS

Neutralization of naphthenic oils and a new dry refining method. E. T. LEBMANS. *Petroleum Z.* 24, 548-9(1928).—The use of powd. lime or lime soln. in the neutralization of naphthenic acids in oil produces an oil which does not emulsify, but has a darker color, high cold test, and bad odor even though treated with bleaching earth. The asphalt obtained contains Ca naphthenates which prevent emulsion formation. Acid-treated oil is first treated with water glass soln. (30 l. for 6000 l. oil) and the acid tar removed by gravity, after which it is neutralized with 1-2% dissolved lime powder at 100°. The oil is orange yellow in color and requires no bleaching earth to complete the refining. M. B. HART

Breaking crude oil emulsions by the use of chemicals. TADEUZ KUCZYŃSKI. *Petroleum Z.* 24, 398-403(1928).—The literature on the formation of, and the various chemicals used for breaking, crude oil emulsions is reviewed. The demulsifying property of various oil-insol. substances with respect to their elec. charge has been studied. The H_2O drops in Boryslav-Tustanowic emulsions are positively charged as contrasted to the negatively charged drops in Texas and California emulsions. H_2O and H_2O solns. are charged positively in highly refined oil, but in unrefined oil acid solns. are pos. and alk. solns. neg. Spent acid, loam and sand are charged negative with respect to crude oil. These facts seem to explain the action of alkali soap solns. as well as sand filtration in natural emulsions. M. B. HART

Shale oils and their cracked products. R. CROSS. *Petroleum Times* 19, 920(1928).—A study of the character of crude shale oils has shown that they vary greatly among themselves, the differences being mainly due to difference in origin. The sp. gr. varies between 12 and 28° A. P. I. Shale oils contain a considerable amt. of wax, 30-70% unsatd., high proportions of nitrogenous compds. and a very low proportion of light hydrocarbons boiling up to 437°. A 52-60% yield of excellent motor fuel may be produced by cracking shale oil by any of the ordinary processes and refining the cracked product in the ordinary way. M. B. HART

Low-temperature shale carbonization in Esthonia. D. BROWNLIE. *Petroleum Times* 19, 1133-6(1928).—The carbonization of "kukkersite" by the Pintsch, Fusion Retort, Grondal-Carlson, Meguin, Dvorkovitz and Crozier processes is reviewed. M. B. HART

Canadian shale oil and bitumen from bituminous sands, as sources of gasoline and fuel oil by pressure cracking. R. E. GILMORE, P. V. ROSEWARNE and A. A. SWINNERTON. *Can. Dept. Mines, Mines Branch* No. 689, 121-32(1928).—Pressure cracking tests on Canadian crude shale oil, and on bitumen from bituminous sands, according to the Dubbs and Cross processes, resp., show that these raw materials are important sources of motor fuel. Gasoline yields of 60 to 65% by vol. of the crude shale oil and about 40% by vol. of the dehydrated bitumen are reported. Other products from these oil and bitumen raw materials are coke and uncondensed gas of high calorific value. The quality of the gasoline from the shale oil is good and that from the bitumen exceptionally good. L. W. RIGGS

Oil shale from Rosevale, New Brunswick. A. A. SWINNERTON. *Can. Dept.*

Mines, Mines Branch No. 689, 104-5(1928).—A composite sample of a 26-ton shipment gave on analysis shale oil 15.4, water 3.2, gas 8.9, spent shale 72.5%. The gas was at the rate of 2330 cu. ft. per ton of shale. The shale oil was at the rate of 34.7 Imp. gal. per ton.

L. W. RIGGS

Pritchard process for the distillation of oil shale. R. E. GILMORE AND A. A. SWINNERTON. *Can. Dept. Mines, Mines Branch No. 689, 106-20(1928).*—The main feature of the Pritchard process is the recirculation of the uncondensed gases through the charge. The app. is illustrated by 2 photographs and 2 diagrammatic sketches, its operation is described in detail and data sheets of 3 tests are shown.

L. W. RIGGS

Contribution to the study of turbine oils, transformer oils and automobile oils. A. R. MATTHIS. Ateliers Construction Electriques Charleroi Belgium. *Intern. Congress Testing Materials 1927, II, 469-78.*—M. reviews factors which influence the quality of turbine, transformer and automobile oils. In order to have good aging qualities the oils must be well refined, i. e., as free as possible from unsatd. hydrocarbons. It is proposed to test the oils for their aging quality by heating in air at 200°, and noting the time necessary for the incipient pptn. of sludge.

G. C.

Basic viewpoint on the determination of resistance of insulating oils. G. WEIZ. *Petroleum Z. 24, 404-7(1928).*—The various conditions under which oxidation tests of oils are made in various countries are described.

M. B. HART

The action of light on transformer oils. GEORG INCZE. Ganzschen Elektrizitäts A. G. *Petroleum Z. 24, 743-4(1928).*—Fifteen samples of American, Russian and Galician transformer oils have been subjected to the light for 3 years, and samples tested at intervals for sludge value, tar no. with Cu, tar-forming no. and acid no. The data obtained indicate that the 3 oils are affected by the light to a measurable degree in 3 months. The Russian oil is least effected, the American and Galician in increasing order. The tar value with Cu shows the greatest change. Oil stored in tin cans in the dark shows no change provided the cans are filled completely and are clean and filled with as little access to air as possible.

M. B. HART

Testing the stability of mineral oils, particularly of transformer oils toward oxidation by air. EVERT NORLIN. Schwedische Materialprüfungsamt, Stockholm. *Intern. Congress Testing Materials 1927, II, 428-36.*—A review covering the description of the oxidizable hydrocarbons present in oil, and the methods of testing now in use. N. advocates the use of pure O₂, around 110-120°, in the presence of pure Cu, and the detn. of sludge acid in the oil and acid in the sludge.

G. CALINGAERT

The testing of lubricating oils in Germany. HILLIGER. *Intern. Congress Testing Materials 1927, II, 437-46.*—H. enumerates the routine tests applied in Germany to lubricating oils. It is pointed out in the discussion that the viscosity as detd. in a viscometer is a poor indication of the lubricating quality of the oil on account of the lack of pressure.

G. CALINGAERT

Injurious properties of lubricating oils on use. FRITZ FRANK AND HANS SELBERG. *Petroleum Z. 24, 641-4(1928).*—A series of 12 Russian and American lubricating oils have been tested by treating 10 g. samples in 50 cc. containers at 100° with O₂ for 9 hrs. The O₂ was regulated to pass through at the rate of 1 bubble per sec. The sample was titrated for the acid content. A comparison of the acid no., sapon. no., sludge content of the oils with the Hackford values for the same oils shows that Russian oils are less apt to form saponifiable products than American oils having a lower Hackford value. Paraffin base oils are more easily oxidized than naphthenic base oils, according to the results. The analyses of the oil and the results of tests are tabulated.

M. B. HART

Viscosity most important property. H. C. MOUGEY. General Motors Corp. *Oil & Gas J. 27, No. 18, 149-50, 155(1928).*—Of the various properties of lubricating oil, the viscosity is of greatest importance.

M. B. HART

Observations on the measurements of the friction coefficient of lubricating oils. PAUL WOOD. Université de Strasbourg. *Intern. Congress Testing Materials 1927, II, 409-14.*—Friction between solid surfaces belongs to 1 of 3 types: A, dry, without any lubricant, liquid, solid or gas between the surfaces; B, oily or imperfect, in which a lubricant is present in thin layers, and C, hydrodynamic or perfect, in which a continuous thick layer of lubricant is present. In practice only B and C are encountered. B is affected by the solid surfaces, and depends mostly upon the oiliness of the lubricant. In C, the surfaces play no part; the friction takes place only within the lubricant, and viscosity is the only factor. The results obtained on the current types of friction machines are of little value because the operating conditions are not well known. In measuring the wear of different metals, W. suggests the use of a standard, reproducible

lubricant, composed of 99 pts. of pure cyclohexanol and 1 pt. of pure stearic acid, which has the following characteristics: d_4^{15} 0.95318; coeff. of expansion 0.000651; abs. viscosity: 0.1743 at 34.8°, 0.0824 at 50.8°.

G. CALINGAERT

The viscometry of lubricating oils.* I. WOLFGANG OSTWALD AND ARTHUR FÖHRE. *Kolloid Z.* 45, 166-78(1928).—The decisive hydrodynamic criterion for the suitability of lubricating oils is viscosity and there is a simple relation between viscosity and lubricating power. Adhesion may be disregarded as it is approx. the same with all liquids. At the same time many investigators dissent from the view that viscosity and lubricating power are related and consider "oiliness" at least as important as viscosity. The detn. of viscosity involves friction resistance to flow. Osborne-Reynolds showed there was laminar and turbulent flow. The Hagen-Poiseuille law holds for the first and Osborne-Reynolds-Blasius law holds for the second flow. These are (1) $w = \eta(dv/dx)$, where w = resistance, v = velocity at distance x from the wall of the capillary, dv/dx = rate of fall in velocity and η = viscosity and (2) $w = \eta \bar{v}^{-1.76}$, where \bar{v} = av. velocity per cross section of the tube. There is a third law for colloidal

systems $w = \eta \bar{v}^{-\frac{1}{n}}$. For the evaluation of such oils it is advisable to use the simplest possible conditions. Accordingly, laminar flow is used, but for research, conditions are different. Turbulent flow is of interest in oils for high-speed machinery, and it is clear under these conditions a different kind of lubrication takes place. Mineral oils have long been considered as sols. With these considerations in view O. and F. used the more modern methods of pressure viscometry for some typical lubricating oils to investigate how far the Hagen-Poiseuille's law holds, the effect of temp., of mech. treatment and of solids and liquids addns. The app. consisted of a capillary viscometer joined to a manometer, of dimensions and details described. Seventeen kinds of oil available in commerce were used as investigation material to which could be added com. graphite, talc, lanolin, Marseilles soap, oleic acid, Ac(OH or alc. potash. With the velocities and tubes used at 25° and without any addns., all but 2 of the 17 obey Hagen-Poiseuille's law just as well as glycerol but values of abs. viscosity are either much above or much below that of glycerol. Temp. has a large effect on the ratio of the viscosity of the oils at 10° and at 100° being 360/1 and this suggests the behavior of a colloidal system. A mathematical expression is given for the temp. function of viscosity and its implications are discussed. II. *Ibid* 206 79.—It is well known that previous mech. treatment affects the viscosity of many colloids. Hence the oils, both free and with addns., were automatically rubbed in a motor for 120 hrs. After 20 hrs. 3 out of the 4 oils tested showed a considerable increase in viscosity. The variations over the period of the 120 hrs. treatment are discussed in relation to clay suspensions, NH_4 oleate and cellulose esters. It seems that in lubricating oils rod-shaped micelles occur as in oleate sols and that mech. treatment modifies the formation. There may be an oxidation effect, too, but oxidation alone cannot account for the total effect, though under actual technical lubricating process the chem. influence must be great. Addn. of acids causes a depression in the abs. viscosity. Addn. of alkali has the opposite effect of acids, i. e., a general increase in viscosity. Addn. of soap in most cases increased the depression of viscosity. Lanolin slowly augments the viscosity. Graphite augments viscosity as does talc.

S. L. B. ETHERTON

Asphalt manufacture. M. WILLIAMS. *Oil & Gas J.* 27, No. 13, 150, 162, 164 (1928).—The asphalt topping plant at the Norco refinery of the New Orleans Refining Co. uses the Trumble process in which crude is passed through residuum heat exchangers and a pipe still to the vaporizing tower in which the hardness of the asphalt is controlled by temp. regulation, unvaporized crude being removed from the bottom of the tower. The temp. of the tower is maintained by the circulation of flue gases through the annular space between it and an outer shell. The product is steam refined.

M. B. HART

Asphalt determination in paraffin-containing oils. J. MZOUREK. *Petroleum Z.* 24, 403-4(1928).—See C. A. 22, 4786.

M. B. HART

Importance of standard thermometers in the testing of materials [petroleum] (FULWEILER) 1. Chemical analysis and evaluation of gasoline and benzene motor fuels (KATTWINKEL) 21. coal, etc. [mineral oils] (Fr. pat. 638,325) 21. Destructive hydrogenation (Brit. pat. 285,879) 21. Cooling and straining device for separating oil or other vapors from gases (Brit. pat. 285,928) 1. Alkylating lead (U. S. pat. 1,690,075) 18.

Cracking petroleum. JOHN J. JAKOSKY. U. S. 1,689,590, Oct. 30. Material to be cracked is passed under pressure through a retort heated to a cracking temp. and sufficient pressure is maintained to cause the uncracked material to remain substantially in liquid phase while permitting vaporization of cracked products, the latter are removed at a plurality of points distributed along the retort and are subjected to elec. pptn. to remove liquid particles from them and the liquid particles are returned to substantially the point in the retort where they escaped from the latter. An app. is described.

Cracking petroleum oil. GUSTAV EGLOFF (to Universal Oil Products Co.). U. S. 1,688,861, Oct. 23. Residuum accumulating in the reaction zone of a pressure cracking app. is withdrawn and passed through a cooling zone and then delivered to a tank filled to at least 50% its capacity with liquid SO_2 and is violently agitated with the SO_2 ; after the agitation is discontinued the materials are allowed to stratify into 2 layers which are separately drawn off and treated to obtain lubricating oil from the upper stratum and cylinder stock from the lower stratum. An app. is described.

Converting petroleum oils. AUBREY D. DAVID (to Universal Oil Products Co.). U. S. 1,688,855, Oct. 23. Oil is heated to a cracking temp. while passing as a stream through a heating coil or the like and the highly heated oil is transferred to an enlarged reaction chamber in which a substantial body of oil accumulates and in which no additional rise in temp. occurs. Vapors are taken off from the enlarged chamber for condensation and collection and residual oil is continuously withdrawn from the enlarged chamber without recirculating any portion of the oil through the heating zone. A swirling motion is maintained in the oil in the enlarged chamber to hold the C in suspension, by continuous withdrawal of some of the oil from the chamber and returning the oil tangentially. An app. is described.

Distilling petroleum oils. GEORGE W. WATTS (to Standard Oil Co. of Ind.). U. S. 1,689,606, Oct. 30. A stream of oil is introduced into a mixing device into which superheated steam also is introduced while reducing its pressure so that expansion of the steam is effected simultaneously with the introduction of the oil and the steam supplies at least such heat as is required for vaporization of the desired fraction of the oil; the mixt. of steam and oil is conveyed in const. flow through an externally unheated passage until substantially equil. conditions are attained at a predetermined temp. and pressure without sepn. and the resulting liquids and vapors are led to a sepg. chamber. An app. is described.

Refining petroleum distillates. ERNEST B. PHILLIPS and JAMES G. STAFFORD (to The Gray Processes Corp.). U. S. 1,687,992, Oct. 16. In order to remove "sour" constituents, a liquid stream of the oil is caused to flow, substantially free from water, first through a body of finely divided CuCl_2 and then through a body of finely divided fuller's earth. An app. is described.

Cracking hydrocarbon oils. JOHN E. BELL (to Sinclair Refining Co.) U. S. 1,688,325, Oct. 23. Oil is circulated from a bulk supply drum to the lower end of a vertically arranged heating tube and upwardly through heating tubes and back to the bulk supply drum from the upper end of the heating tubes. In the heating tubes it is heated to cracking temp. by hot combustion products which pass first into contact with the upper portion of the tubes and thence downwardly along the latter. Direct radiation from the fire-box to the heating tubes is prevented. The app. is described in detail.

Cracking hydrocarbon oils. GUSTAV EGLOFF and HARRY P. BENNER (to Universal Oil Products Co.). U. S. 1,688,859, Oct. 23. At least 10% of a solid bitumen such as bituminous coal is dispersed in colloidal form in an oil such as fuel, Mexican or Calif. oil and the mixt. is subjected to a cracking temp. under pressure.

Cracking hydrocarbon oils. GUSTAV EGLOFF (to Universal Oil Products Co.). U. S. 1,688,860, Oct. 23. The oil is heated to a cracking temp. under pressure in an initial stage, the vapors formed are dephlegmated and condensed and the unvaporized oil is passed to a top-fired secondary heating zone and subjected to higher temp. and pressure. Vapors thus formed are dephlegmated and collected separately from those produced in the first stage. An app. is described.

Cracking hydrocarbon oils. ROBERT T. POLLOCK (to Universal Oil Products Co.). U. S. 1,688,830, Oct. 23. In a continuous cracking process, the oil is subjected to cracking conditions of heat and pressure in a cracking zone and evolved vapors are passed through a dephlegmating zone in which they are caused to commingle with

incoming charging oil and a supply of water. The charging oil together with reflux condensate sep'd. from the vapors in the dephlegmator and with the unvaporized water is passed to a separator from which the water is withdrawn, and mixed reflux condensate and charging oil are passed from the separator to the heating zone. Dephlegmated vapors from the dephlegmator are passed to a condenser. An app. is described.

Apparatus for cracking hydrocarbon oils under pressure. JOHN PERL (to Sinclair Refining Co.). U. S. 1,689,362, Oct. 30. Connections are provided for circulating and recirculating a liquid body of oil in a still and through a tubular heater and for circulating heating gases around the tubes of the heater. The inner surface of the tubes of the heater is coated with Sn. U. S. 1,689,363 specifies the use of a generally similar app. in which, however, the surface of heater tubes which is in contact with the oil is coated with Fe sulfide which serves to prevent deposition of carbonaceous solids.

"Cracking" mineral oil. PAUL GRENE. Fr. 638,517, Dec. 6, 1926. To avoid the formation of compact deposits of coke or graphite in "cracking" mineral oils, catalysts having a basis of C are used, such as wood charcoal, coke, animal black or decolorizing C.

Cracking and hydrogenating oils. P. GRENE. Brit. 285,668, March 21, 1927. An app. is described in which heavy oils such as those obtained by distg. coal are cracked and hydrogenated by passing them (preferably mixed with neutral gases) through heated tubes contg. superposed layers of (a) non-metallic porous catalyst such as activated C, (b) oxides of Mn or Sn, (c) porous catalyst similar to layer "a," and, (d) a hydrogenating catalyst such as Ni. Blast-furnace gases contg. oxides of C may be used for the neutral gases and the H used may be derived from decompn. of H₂S formed from S compds. in the oil or may be derived by reaction of the oxides of C of the neutral gases with H₂O vapor.

Hydrogenating oil and coal products. G. HUGEL, M. PAUL and M. BOISHEL. Brit. 286,206, Feb. 28, 1927. Hydrogenation of org. substances such as products of distn. of coal and petroleum is effected by use of hydrides of alkali or alk. earth metals either previously formed or produced *in situ* during the process. Pitch from coal tar may be hydrogenated at a temp. of about 300° and a pressure not exceeding about 100 kg., about 10% of Na hydride being used. An app. is described.

Hydrogenating and purifying liquid and gaseous hydrocarbons. H. ROSTIN. Brit. 286,255, March 1, 1927. Oils from cracking or destructive distn., coal gas, water gas or other liquid or gaseous hydrocarbon products are hydrogenated and purified by passage with H₂S over iron which is preferably finely divided and freshly reduced. A temp. of 200-300° is suitable for treating coal gas or water gas and when the iron is converted into sulfide the flow is stopped and H or gases contg. H are passed through the material to reform Fe and H₂S.

"Constructive conversion" of heavy hydrocarbons to lighter products. WM. E. SHORE. U. S. 1,687,595, Oct. 16. Oil such as crude petroleum is directed through the jacket of a compressor, then introduced together with H-bearing gases to a mechanically operating atomizer and the vapor produced is passed to the compressor cylinder and heated by compression; the highly heated vapor is then passed to expansion condensers. An app. is described.

Converting lower-boiling into higher-boiling hydrocarbons. ALEXANDER S. RAMAGE (to Gyro Process Corp.). U. S. 1,687,890, Oct. 16. A hydrocarbon vapor similar to the lighter fractions of casing head gasoline is mixed with steam and the mixt. is brought into contact with ferrous oxide at a temp. of 600° or higher, in order to form a fuel for *internal-combustion engines*. An app. is described.

Purification of aromatic hydrocarbons. THE SELDEN COMPANY. Fr. 636,485, June 23, 1927. Hydrocarbons from different fractions of coal tar or petroleum tar distn., or oils from washing gas rich in benzene, are submitted to a differential halogenation to convert the impurities into easily separable substances. Gaseous or liquid Cl may be used, or substances yielding Cl, such as aqua regia, COCl₂, SO₂Cl₂, etc., for the chlorination. A limited treatment with H₂SO₄ before or after halogenation may be employed.

Manufacture of oil in distillation using a sweeping gas. JOSEPH TRAUTMANN. Fr. 636,329, May 5, 1927. The gas formed in slow or low temp. distn. is itself used as the sweeping gas and is sent to the furnace after being heated, a quantity of gas equal to that produced being continually withdrawn and sent to the oil extn. plant. The extd. gas is burned and used to heat the circulating gas.

Purification of mineral oils and fatty materials. GEORGES MICHOT-DUPONT. Fr. 32,762, Dec. 21, 1926. Addn. to 553,338. After deglycerination of oils and fats in the known manner, the fatty acids thus obtained are submitted to an acid treatment.

e. g., H_2SO_4 , in the presence of substances capable of liberating O such as persalts, and distd.

Preservation of oils. I. G. FARBERINDUSTRIE A.-G. Fr. 636,332, May 6, 1927. Lubricating and transformer oils are preserved from oxidation and polymerization by the addn. of small quantities of org. compds. such as hexamethylenetetramine, trioxymethylene, urea, biuret, piperidine, aldehyde ammonia, aminoguanidine, diphenylguanidine, diethylaniline, hydroquinone, aminophenol, hydroxyquinoline, phenylenediamine, toluhydroquinone, melamine, phloroglucinol.

Apparatus for decanting and filtering used oils. JEAN FRANCOIS JOSEPH FLEPH. Fr. 636,428, June 22, 1927.

Oil extraction retort. GRODZENSKI MENELL. Fr. 638,598, July 30, 1927. Vertical retorts for the extn. of oil from bituminous materials such as shale, coal or peat comprises narrow chambers with sloping plates down which the material slides in zig-zag manner. The retorts may be externally or internally heated.

Digesting shale with oil and cracking evolved products. WM. H. HAMPTON. U. S. 1,687,763, Oct. 16. Material such as bituminous shale is digested with a heavy mineral oil at temps. of 260–370°, steam is mixed with the evolved vapors and the mixt. is subjected to cracking at higher temps., products formed are fractionally condensed, and the residual digestion mixt. is treated with a lighter oil, solid matter is sepd. from the dild. mixt. and a heavy oil fraction is obtained from the residual oil which together with a heavy fraction from the products of cracking is used for digestion of addnl. quantities of raw bituminous material. An app. is described.

Ozonizing mixed liquid hydrocarbons such as those obtained in cracking petroleum oils. ALEXANDER S. RAMAGE. U. S. 1,689,599, Oct. 30. A method is described for producing products which are suitable for *varnish manuf.* Cf. C. A. 22, 2755.

"Cutting oil." MYRON P. DAVIS (to Otis Elevator Co.). U. S. 1,689,011, Oct. 23. Lard oil is heated to about 230–245° while agitated, the heating is discontinued and 20 lbs. finely divided flowers of S are added for each 10 gals. of the oil and after a few min. paraffin oil of a viscosity of about 100 sec. at 37° Saybolt is added in the proportion of 4–7 gals. for each 10 gals. of the lard oil and after all reaction is completed addnl. paraffin oil is added to dil. the mixt.

Stream divided for oil distillation apparatus. CLAUDE F. TEARS (to Universal Oil Products Co.). U. S. 1,688,839, Oct. 23.

Feeding bituminous materials such as schists or brown coal into distillation apparatus, etc. JOHAN G. GRÖNDAL. U. S. 1,687,760, Oct. 16. Mech. features.

Mixing device (with an adjustable Venturi tube) for oil-gas apparatus. ALVIN J. BASSETT (to Bruce Macbeth Engine Co.). U. S. 1,688,320, Oct. 23.

Tank and pipe system, etc., for gathering gas from refinery oil tanks or the like. HARRY R. MAXON. U. S. 1,689,352, Oct. 30. A device is provided which permits the passage of gas from a gathering line to a closed tank when the pressure in the tank falls below atm. pressure but prevents such passage as long as the pressure is maintained at atm. pressure in the tank.

Tower with superposed shelves for contacting solids with liquids. PHILANDER R. GRAY (to Gray Processes Corp.). U. S. 1,688,012, Oct. 16. An app. is specified which is suitable for *purifying hydrocarbon oil vapors* with different reagents.

Apparatus for gravity separation of liquids such as oil and water. W. A. WHITE and WHITE OIL SEPARATORS, LTD. Brit. 285,707, June 7, 1927.

Lubricating oils and fats. SOCIÉTÉ MARITIME ET INDUSTRIELLE. Fr. 636,242, June 20, 1927. Dissolved or liquified rubber is incorporated in lubricating oils or fats to increase their viscosity and adherence. Graphite and plumbago may also be added.

Tetraethyl lead. WM. STANSFIELD CALCOTT, ALFRED EDWIN PARMELEE and FREDERICK REGINALD LORRIMAN. Fr. 638,103, July 22, 1927. See U. S. 1,664,021 (C. A. 22, 1677).

Emulsions of asphalt, etc. LA TRINIDAD. Fr. 636,207, Oct. 15, 1926. Asphalt, bitumen or tar, fluxed with residual oil from gasoline, is emulsified with 3 to 12% of ordinary soap to which 1 to 8% of com. olein has been added.

Carbonizing wood, etc. JEAN SIMON JACQUES SOULIÉ. Fr. 638,232, July 26, 1927. The wood, etc., is placed in a circular container around a circular furnace, and combustion gases pass from the furnace up through the wood while air is drawn up from the atm.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Lignin and cellulose. VII. Remarks on the chemistry of lignin. KARL FREUDENBERG, MAX HARMER AND LAURA MARKERT, IN PART WITH MISS E. SPIESS. Univ. Heidelberg. *Ber.* 61B, 1760-5(1928); cf. *C. A.* 22, 3292.—The literature contains contradictory data on the results of fusing lignin with KOH; 20-30% yields of 3,4-(HO)₂C₆H₃CO₂H (I) are frequently reported. As the purification of the I, especially the removal of the (CO₂H)₂, is difficult and the colorimetric estimation readily leads into error, a series of expts. have been made in which the I was detd. spectrophotometrically in FeCl₃ and gravimetrically as veratric acid. Only about 5% I was found; allowing for unavoidable and detectable losses, it may be asserted that 9-10% I, together with traces of *o*-C₆H₄(OH)₂, are formed. The errors in the earlier investigations were due to the fact that the substance weighed or measured colorimetrically was never pure I. The corrected result indicates that at least 8% of the Willstätter lignin consists of the 3,4-(HO)₂C₆H₃C skeleton; whether the C₆H₅ nucleus is present as such or in a hydrogenated form (quinic acid) is not established by these expts. Eugenol under the same conditions gives a similar low yield of I, and the possibility must be reckoned with that the true content in *o*-C₆H₄(OH)₂ derivs. may be many times more than the 8% found. After many series of expts. with and without Zn dust or Fe powder, it was found that the best results are obtained by adding 7 g. of the lignin to 30 g. KOH and 7 g. H₂O at 100°, raising the temp. to 260° in the course of 45 min. and then to 270° in 15 min. and heating another 15-30 min. at 270°. It was recently found that lignin distd. with 12% HCl gives a little HCHO (0.7% as detd. with barbituric acid). Attempts to increase the yield, dimedon being used to measure the quantity formed, have not, thus far, given more than 1%, and it is still believed that the quantity really present is about 2%. Aliphatically bound HCHO, as in triformal mannitol, is at once split off on the 1st distn. while lignin must be distd. up to as many as 12 times (28% H₂SO₄ can be used instead of 12% HCl); piperonylic acid and narceine yield 60-70% of their HCHO (best with 43% H₂SO₄), narcotine not much more than 20%. From these results it is concluded that the HCHO in lignin is present as a CH₂O group bound to an *o*-C₆H₄(OH)₂ residue. Wood distd. under the same conditions gives HCHO in a yield corresponding to about 1/3 of the lignin; no appreciable quantities have been found in other than the lignin components of the wood. In connection with Kalb and Lieser's paper (*C. A.* 22, 2925) the present authors state that in their earlier expts. the preliminary removal of the wood constituents sol. in alkalis and easily hydrolyzed by acids before treatment with CuO-NH₃ was taken for granted. W. Dürr has now found that after boiling out the pentosans, etc., with 1% H₂SO₄, cellulose dissolves in CuO-NH₃ and yields very light lignins with 16% MeO. Especially advisable is repeated alternating treatment of the wood with hot 1% H₂SO₄ and CuO-NH₃; even 0.1% H₂SO₄ can be used. The compn. of such lignin preps. is about the same as that of the earlier preps. It would seem as if the union between the lignin and cellulose is dissolved by removal of the "wood gum," the pentosans and hemicellulose. A wood so treated and then methylated gives up considerable methyl cellulose to CHCl₃ or AcOH.

C. A. R.

Recent developments in nitrocellulose. J. B. WEISEL. *Chemicals* 30, 31-2(1928)

R. H.

Experiments in producing cellulose ethers and esters with special reference to cellulose nitroacetate. HENRY A. GARDNER AND CALVIN A. KNAUSS. *Am. Paint & Varnish Manufs. Assoc. Circ.* No. 388, 657-72(1928).—The use of cellulose nitrate and acetate in protective coatings is briefly reviewed. Besides these the authors have prepd. the borate, phosphate, formate, propionate, butyrate and benzoate of cellulose. These compds. were usually dark in color or lacking in certain other phys. properties for use in lacquers and are not of com. importance at present. The advantages of cellulose ethers are described, especially that of being sol. in C₆H₆ and homologs, and EtOH. Methods are given for the prepn. of cellulose nitroacetate which appears to have very desirable properties for use in lacquers. It is much less inflammable than the nitrate and films showed higher tensile strength than those made with either acetate or nitrate.

R. J. MOORE

Note on the cymoles formed in the sulfite pulping process. OSSIAN ASCHAN. *Finska Kemistsamfundels Medd.* 36, 123-5(1928).—SO₂ and sulfites at high temp. and pressure tend to split off H from terpenes like pinene and dipentene. The resulting

cymoles may consequently be related as position isomers and A. points out that this may explain some obscure problems in the substitution reactions of these cymoles.

HANS C. DUBUS

Preparation of rayon for weaving. L. A. PALINA. *Cotton* 92, 335-9, 435-40, 665-7, 909-11(1928).

RUBY K. WORTNER

Determining the coating on casein-coated paper. GUSTAVE A. STRICHT. *Chemist-Analyst* 17, No. 4, 7(1928).—The method depends upon weighing shredded paper, digesting it with dil. NH_4OH , passing the liquid through a 100-mesh screen, evapg. and weighing.

W. T. H.

Limestones of the Gaspé Peninsula [for use in the wood pulp industry] (Goudge) 8. Paper pulp from cane (U. S. pat. 1,688,904) 28. Waterproofing and coating paper (Brit. pat. 286,396) 18. Derivatives of starch, cellulose and other carbohydrates (Brit. pat. 286,331) 10.

Extraction of cellulose from vegetable substances. CARL ALFRED BRAUN. Fr. 638,011, July 4, 1927. Cellulose is extd. from vegetable substances by boiling under pressure with lyes contg. alkali sulfite, caustic alkali and alkali salts of resins, fatty acids, silicates, borates, aluminates or zincates, with a slight excess of alkali carbonate.

Cellulose from straw, cornstalks, etc. B. DORNER (to Euromerican Cellulose Products Corp.). Brit. 286,211, Feb. 28, 1927. Chopped and shredded material is sieved to sep. material which may serve as fodder for animals, sol. substances are leached out with water and the material is disintegrated and repeatedly cooked with NaOH solns. of increasing strength. Cf. C. A. 22, 4247.

Treating cellulose derivatives. CAMILLE DREYFUS. Fr. 636,272, June 20, 1927. To lower the viscosity of concd. cellulose ester solns., particularly cellulose acetate, they are treated with H_2O_2 in the presence of Fe or Fe salts. Ferrous salts, specially ferrous acetate, are preferred, and they may be added during esterification while the H_2O_2 is added after esterification.

Cellulose esters. I. G. FARBENIND. A.-G. Brit. 285,858, Feb. 23, 1927. Esters of cellulose or of its conversion products with butyric, propionic and other higher aliphatic acids are prepd. by reacting on the cellulosic material with a halogenated acetic acid anhydride and butyric acid or other acid corresponding to the ester to be formed in the presence of a catalyst such as monochloroacetic acid or H_2SO_4 . The esters first formed may be modified by hydrolyzing.

Films of cellulose esters and ethers. ARTHUR EICHENGRÜN (to Celanese Corp. of America). U. S. 1,688,457, Oct. 23. In forming thin films, a soln. of the cellulose deriv. is spread in a very thin layer upon a base comprising a cellulose deriv. other than that used for the production of the film (e. g., a soln. of alc.-sol. ethyl cellulose may be spread upon a base of cellulose acetate) to which has been added a substance (suitably glycerol or paraffin with a base of cellulose acetate) which diminishes the adhesiveness of the dried film formed on evapn. of the solvent even if the film be extremely thin. The soln. used for making the film contains no substance acting as a solvent for the base. The film may be formed, stripped and rolled as a continuous band.

Decorating surfaces with cellulose esters. M. SMITH. Brit. 286,006, Nov. 29, 1926. Tennis racket handles, elec. lamps or other articles to be decorated are overlaid with a yarn or fabric such as cellulose acetate which is then treated with a solvent such as EtOAc which at least partly dissolves the material applied and causes it to adhere to the surface. Various details and modifications are described.

Saccharification of cellulose. JOHN PERL (to M. M. Cory). U. S. 1,687,785, Oct. 16. Cellulosic material such as ground wood fiber is subjected, before saccharification by hydrolysis, to a pretreatment comprising neutralizing the natural bases and any alkali present in the material with H_2SO_4 . Cf. C. A. 22, 3300.

Treating soda-cellulose liquors. B. DORNER (to Euromerican Cellulose Products Corp.). Brit. 286,210. Waste liquors resulting from the soda process of making cellulose from "maize or other straw," wood, etc., are treated to obtain substances for use as animal foods or for fermentation to produce alc. by use of CO_2 or purified flue gases which are supplied to the liquor until it is no longer alk. to litmus followed by boiling to effect concn. and pptn. The liquor may be further treated with CO_2 after cooling to effect addnl. pptn.

Use of chromium-surfaced rollers or other implements in finishing films of cellulose nitrate or other cellulosic materials. KEVIN W. SCHWARTZ (to United Chromium, Inc.). U. S. 1,688,060, Oct. 16.

Cellulose formates. EGON ELÖD. Fr. 638,431, July 29, 1927. See Brit. 275,641 (C. A. 22, 2273).

Cellulose xanthate. PIERRE MORO. U. S. 1,689,958, Oct. 30. Alkali cellulose is compressed to obtain less than 300 parts for each 100 parts of cellulose, the material is reduced to very small particles and is mixed with a high-grade soln. of S in CS_2 while heating to 30–40°. An app. is described.

Cellulose for artificial silk. HERMANN SUIDA and HANS SADLER. Fr. 636,381, June 21, 1927. Cellulose is prep'd. for artificial silk manuf. by disintegrating beech wood by a mixt. of dil. HNO_3 , and H_2SO_4 , contg. 15–25% HNO_3 and less than 10% H_2SO_4 , at a temp. not above 85°, removing excess acid and treating with alk. lye.

Artificial silk. G. BONWIR. Brit. 285,863, Feb. 24, 1927. The process for prep'g. a "viscose silk" of reduced luster, described in Brit. 285,066 (C. A. 22, 4816), is applied to artificial silk made from other cellulose derivs. such as that from cellulose, cellulose hydrate, nitrate or acetate or cellulose ethers or mixed cellulose derivs. Added substances at least relatively immiscible with the soln. of the cellulose deriv. are used such as PhCl , xylene, hydrogenated naphthalenes or mineral oils of high b. p.

Artificial silk. SAHICHI OHSAKA. Fr. 636,396, June 21, 1927. To the spinning soln. of viscose, cellulose acetate, denitrated nitrocellulose, or copper-oxide-ammonia cellulose, etc., for artificial silk threads or films, is added a vegetable or animal protein and the fatty oils occurring naturally therewith. The resistance and elasticity of the thread are thereby increased.

Artificial silk. I. G. FARBEININD. A.-G. Fr. 638,181, July 23, 1927. An artificial silk which is uniformly wettable is made by acting on the artificial silk during its manuf., e. g., before spinning, with wetting agents, such as naphthalenesulfonic acid, or the sulfonic acids obtained by the action of chlorosulfonic acid on solar oil or solvent naphtha.

Artificial silk. SOCIÉTÉ CHIMIQUE DES USINES DU RHÔNE. Fr. 638,448, July 29, 1927. To obtain a mat surface on cellulose acetate silk, BaSO_4 is ppt'd. in the acetate after its formation by the addn. of H_2SO_4 and then BaCl_2 in dil. AcOH . The whole is ppt'd. by diln. and washed and treated as usual.

Artificial silk, etc. HENRY DREYFUS. U. S. 1,688,531, Oct. 23. Artificial filaments are dry spun from conc'd. solns. of cellulose derivs. such as cellulose acetate contg. not less than 25% of the cellulose deriv. U. S. 1,688,532 specifies the use of less than 15% (calcd. on the wt. of the cellulose deriv.) of a high b. p. liquid such as triacetin or diacetin which is not completely removed during the spinning operation.

Artificial silk from viscose. H. J. J. JANSSEN and HARBENS (Viscose Silk Manufacturers), Ltd. Brit. 285,958, Nov. 20, 1926. A soln. of salts or acids such as HCl , H_2SO_4 , HOAc and Na_2SO_3 is intimately mixed with the viscose as it passes to the spinning nozzles and the material may be heated and then spun into a coagulating bath of the usual compn. An app. is described. The yarn produced has a dull luster.

Viscose artificial silk. DEUTSCHE ZELLSTOFF TEXTILWERKE G.M.B.H. Fr. 636,264, June 20, 1927. Silk obtained by spinning viscose is submitted on a perforated bobbin to all the necessary baths for its final treatment, the baths being projected through the body of silk and the bobbin. In order to use Na_2S as desulfurizing agent bobbins of inoxidizable steel or of ceramic material or bobbins covered with rubber, gum lac, etc., are used.

Viscose artificial silk. DEUTSCHE ZELLSTOFF TEXTILWERKE G.M.B.H. Fr. 636,265, June 20, 1927. Silk obtained by spinning viscose is submitted on a perforated Al bobbin to all the necessary baths for its final treatment, the desulfurizing bath consisting of a warm dil. soln. of salts of feeble acids, having an alk. reaction, e. g., a soln. of Na_2SO_3 .

Apparatus for making "viscose silk." NAAMLÖÖZE VENNOOTSCHAP NEDERLANDSCHE KUNSTZIJDEFABRIEK. Brit. 285,890, Feb. 25, 1927. The thread is subjected to a gradually increasing tension during its passage from the spinning nozzle to the winding device. A normal viscose is used and it is spun into a normal spinning bath at a temp. above 18°.

Apparatus for producing artificial silk. K. HAGIWARA. Brit. 286,086, March 1, 1927. To assist the passage of the filament-forming soln. through spinning nozzles or through a filtering surface, an electrode is placed in the soln. in advance of the nozzle or filtering surface and a second electrode is placed in the coagulating bath or in contact with the winding bobbin or behind the filtering surface, to assist in the desired migration of the material to be spun. With viscose, gases produced during the spinning operation are decomp'd. and rendered innocuous by the elec. discharge.

Apparatus for making artificial silk and winding it under regulated tension. I. G. FARBEININD. A.-G. Brit. 286,292, March 4, 1927.

Metallic bobbin for artificial silk. ÉTABLISSEMENTS J. CHUIT. Fr. 32,841, July 20, 1926. Addn. to 629,455. The body of the bobbin is in 2 pieces obtained by stamping.

Bobbins for artificial silk. THE MANHATTAN RUBBER MANUFACTURING COMPANY. Fr. 636,553, June 24, 1927. The bobbins are made hollow with a large no. of perforations, the interior and exterior being entirely covered with a thin layer of rubber vulcanized to a degree between softness and extreme hardness.

Artificial silk from cuprammonium cellulose solutions. HERMANN SCHMIDT and EMIL HUBERT (to I. G. Farbenind. A.-G.). U. S. 1,689,895, Oct. 30. The soln. is spun into an aq. pptg. bath contg. dissolved CO_2 which serves to give the product improved elasticity and tensile strength. Cf. C. A. 22, 2840.

Artificial filaments. RUDOLF SAJITZ and FRIEDRICH POSPIECH (to Chemische Fabrik Pott & Co.). U. S. 1,689,894, Oct. 30. The spinning qualities of solns. such as those of cellulose acetate, viscose or cellulose are improving by treating the solns. with pptg. agents such as H_2SO_4 and Na_2SO_4 soln. in the presence of Na β -isopropyl-naphthalenedisulfonate or other suitable naphthalenesulfonic compds. contg. substituted alkyl radicals and several sulfo substitution groups in the ring.

Kraft pulp. GEORGE A. RICHTER (to Brown Co.). U. S. 1,689,534, Oct. 30. Wood chips or other raw cellulosic material is digested in a liquor contg. Na sulfide, the pulp is sepd. from the spent liquor and the latter is concd. and evapd. and its inorg. content is smelted, and substantially all the Na and S values are recovered in the form of sublimed solids and SO_2 which are formed in the smelting and are absorbed in alk. aq. liquor, for further recovery in the smelting.

Beater for paper pulp. LEONARD E. RANDECKER (to Hammermill Paper Co.). U. S. 1,689,932, Oct. 30.

Caustic alkali from "black liquor" of paper pulp manufacture. W. BARRS and E. BARRS. Brit. 285,933, Oct. 18, 1926. The liquor is concd. by direct contact with hot gases such as hot waste flue gases used in incinerating the alkali or air heated by them. Ash derived by burning the concd. liquor is lixiviated with weak alk. liquors and the Na_2CO_3 thus obtained is treated with an aq. soln. of spent lime. An app. and various details of operation are described.

Beating "engine" for paper pulp. J. WHITE. Brit. 286,461, March 9, 1927.

Rotary refiner for paper stock or pulp. EDMUND P. ARPIN, JR. U. S. 1,689,190, Oct. 30.

Paper-making apparatus. ROBERT E. READ (to International Paper Co.). U. S. 1,687,847, Oct. 16.

Apparatus for making paper, cardboard or pasteboard. OTTO LEONHARDT. U. S. 1,689,553, Oct. 30.

Suction apparatus for paper-making apparatus. MAX WENZEL. U. S. 1,688,216, Oct. 16.

Stock-regulating apparatus for paper-making machines. JOHN R. SPOOR. U. S. 1,689,755, Oct. 30.

Apparatus for calendering paper. A. L. DAWE. Brit. 286,020, Dec. 8, 1926.

System of marking "safety paper" with substances which will disclose use of ink "eradicators." BURGESS W. SMITH (to Todd Co.). U. S. 1,689,302, Oct. 30.

Multi-ply fiber board. FREDERICK P. WOOD (to Simplex Paper Corp.). U. S. 1,689,812, Oct. 30. Outer plies are united with an intermediate ply which has been treated with water to expand the fibers and with a deliquescent substance such as glycerol serving to fix the fibers in expanded condition. A soap soln. also may be used.

Fire-resisting fiber board. CHARLES A. UPSON (one-half to W. Harrison Upson). U. S. 1,687,599, Oct. 16. Webs of vegetable fiber pulp of relatively high tensile strength and of mineral fiber pulp of lower tensile strength are united immediately after their formation and while satd. to form a composite board, the fibers of which are interlaced with each other.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Blasting explosives. B. A. GILLIE. *J. Chem. Education* 5, 1213-23(1928).—A view. E. H.

The Safety in Mines Research Laboratories, Sheffield: a description. ANON. Safety Mines Research Board (London), *Paper No. 44*, 3-19(1928). E. H.

Glycerol and its substitutes [in dynamite industry] (DARKE, LEWIS) 27.

Explosives for blasting. RALPH A. LONG (to Atlas Powder Co.). U. S. 1,689,674, Oct. 30. Explosives are formed contg. nitroglycerin up to 8%, NH_4NO_3 , trinitrotoluene and a non-explosive combustible material such as ground wood. The nitroglycerin and trinitrotoluene together constitute a sensitizer not in excess of 12% of the compn. and the quantity of nitroglycerin is greater than that of the trinitrotoluene.

Cartridge wad composition. S. C. BOND (to Bond Mfg. Corp.). Brit. 286,238, March 1, 1927. Wads are made from cork powder impregnated with a larger quantity of a binder formed of paraffin or wax 2 and asphalt 8 parts.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

A history of dyestuffs. II. ALBERT P. SACHS. *Textile Colorist* 50, 244-6(1928); cf. C. A. 22, 2059. RUBY K. WORNER

The Durand and Huguenin plant at Basle. CHAS. F. MULLIN. *Clemson Coll. Am. Dyestuff Rept.* 17, 671(1928).—A description of the work at this plant, especially with reference to the Indigosols, is given. L. W. RIGGS

Light shades on silk. JAMES STAPLE. *Textile Colorist* 50, 180-1(1928).—Bleaching and drying with the basic dyestuffs. CHAS. F. MULLIN

Extracts of osage orange and "yellow wood." GABRIEL DESMURS. *J. Intern. Soc. Leather Trades Chem.* 12, 424-9(1928).—Osage orange ext. ("aurantine") was compared as to tinctorial properties with yellow wood ext. ("Cuba ext."). The former may often be used in place of the latter, but differences in the shades produced with different mordants require that the substitution be done with caution. Tests for distinguishing aurantine from Cuba ext. are described. On unmordanted wool the aurantine gives colors more yellow and less orange than does Cuba ext. With variously mordanted wools the colors produced are as follows: (A = aurantine, C = Cuba ext.): Sn salts—dull golden yellow (C), bright golden yellow (A); Al salts—brownish yellow (C), dull yellow (A); Sn and Al salts—orange yellow (C), golden yellow (A). On cotton mordanted with 1% $\text{UO}_2(\text{NO}_3)_2$ aurantine gives a yellow-orange and Cuba ext. a red-orange shade. H. B. MERRILL

The A B C of dyeing. NOEL D. WHITE. *Cotton* 91, 835-7, 943-5, 1049-51, 1147-9, 1299-300; 92, 75-9, 187-9(1927); 92, 306-10, 407, 410, 513, 515, 629-30, 761-3(1928).—A series of practical articles based chiefly on personal experience. The following subjects are discussed: Boil-off and dyeing in 1 and 2 baths and the use of CH_3COOH in dyeing and finishing hosiery; matching a sample in the lab. and adaptation of the formula in the dyehouse; repairing damaged shades from known and unknown causes; uneven dyeing and spotted work, causes, prevention and remedies; difficulties in matching colors in and out of the dyehouse; importance of light, location of the dyehouse, and knowledge of the properties of dyestuffs; stripping and redyeing, occasion, stripping agents and procedure; bleaching with KMnO_4 , H_2O_2 and Na_2O_2 ; bleaching with Cl; experiences using chloride of lime and soda ash on cotton. RUBY K. WORNER

Practical hints in the production of bright colors on textile fabrics. XXXIX. RAFFAELE SANSONE. *Am. Dyestuff Rept.* 17, 561-4, 578, 592-4, 629-30, 639-40(1928); cf. C. A. 22, 3780.—Rotary drum drying by circulating hot air in place of steam is described. Details are given for the prepn. of color pastes. Methods of producing color contrast effects are described. Ombre effects in 2 colors and in 3 or more colors are considered. L. W. RIGGS

Effect of light on colored fabric. II. EVA HIBBERT. *J. Soc. Dyers Colourists* 44, 300-1(1928); cf. C. A. 21, 4075.—When placed in aq. solns of isatin, cotton showed no affinity, silk a little and wool considerable affinity for the dye. The wool and silk were colored a dull yellow and cellulose acetate silk a golden yellow. When cotton dyed with indigo had slightly faded the isatin extd. from it dyed cellulose acetate silk yellow. The action of ordinary light on cotton dyed with *o*-toluene-azo-*o*-naphthol caused a fading of the orange color at a slow rate, but when exposed to the light of a quartz-Hg vapor lamp, crystals formed on the surface of the cloth within 3 min. The crystals appeared to be a phys. modification of the dye which could be restored to the original form by soln. in CHCl_3 and evapg. L. W. RIGGS

Palatine-fast colors in wood dyeing. CHARLES GEORGE. *Textile J. Australia* 3, 283-4(1928).—Properties and application are discussed. CHAS. F. MULLIN

Preparatory processes influencing dyeing. L. L. LAOYD. *Wool Record* 34, 917 (1928).—General, dealing with the effect of scouring, moisture content in the spinning and weaving processes, assisting agents and mildew on the dyeing properties of animal fibers. To prevent mildew, wool stock should be scoured and chromed before storing.

RUBY K. WORNER

Vat dyeing piece goods. ORMOND W. CLARK. *Am. Dyestuff Rept.* 17, 617–22 (1928).—The 3 fundamental methods of vat dyeing piece goods are jig dyeing, padding with reduced vat dyestuff, and padding with unreduced vat dyestuff with a subsequent passage of the cloth through a reducing process. These processes are described in detail.

L. W. RIGGS

Capillarity in connection with dyeing. RICHARD CAMERON. *Textile Colorist* 50, 183–4 (1928).—The importance of capillarity in connection with the penetration and level dyeing properties of dyestuffs is pointed out.

Dyeing of mixed fibers and fabrics. WM. BENNETT. *Silk J.* 4, No. 44, 60 (1928); cf. *C. A.* 22, 872.—Resist effects on cotton-celane goods with S dyestuffs are described.

CHAS. E. MULLIN

Treatment and dyeing of natural silk and viscose mixtures. WM. BENNETT. *Silk J.* 4, No. 45, 51 (1928).—A general discussion with suggestions.

C. E. M.

Capillarity test and the dyeing of rayon. ALAN A. CLAFLIN. *Am. Dyestuff Rept.* 17, 650, 677 (1928).—The test, as given by Whittaker in his book on textile dyeing, is checked and discussed. The capillary crawl of dyestuffs is retarded by raising the p_H of the dye bath, and it is not a function of the surface tension of the soln. It appears to be a phenomenon of soly. and is equalized by the addn. of glycerol to the dye bath.

L. W. RIGGS

Rayon dyeing precautions. A. E. HANSON. *Rayon J.* 3, No. 1, 26–9, 44–5 (1928).—Monel metal is suggested. When stripping with Ti compds. it is necessary to use a short bath in order to avoid discoloration of the monel metal.

CHAS. E. MULLIN

Dyeing furs with ursols. E. HANSEN. *Textile Colorist* 50, 162–4 (1928).—Methods and formulas are given.

CHAS. E. MULLIN

The absorption of leuco dyes by cellulose. KURT BRASS AND GUSTAV TORINUS. *Kolloid Z.* 45, 256–66 (1928).—When viscose is treated with indigo in the presence of CaO in a Zn-lime vat both are absorbed but not in equiv. proportions. Shaking the material increases the absorption of indigo greatly but only slightly that of CaO. The latter is absorbed reversibly and is not influenced by the presence of indigo. The distribution coeff. is independent of the alkali content in the hyposulfite vat. The nature of the dyes does not influence the distribution of $\text{Ca}(\text{OH})_2$ between cellulose and vat soln. Dyes studied were: thioindigo, algol yellow, helidone yellow, indanthrenes orange, red golden orange, blue and yellow. The variation in distribution coeff. is closely related to the chem. constitution and is most pronounced in complex condensed cyclic group dyes such as indanthrene and flavanthrene. It is not certain that chem. combination occurs between cellulose and leuco dye.

R. H. LAMBERT

Jute bleaching and dyeing. FRED. GROVE-PALMER. *Dyer, Calico Printer* 60, 124–5, 140–1 (1928).—Methods are described for bleaching jute with hypochlorite, peroxide and permanganate. Practically all classes of dyes can be used without difficulty. Lists of basic, acid, direct and S dyes especially suited, and suggestions with regard to precautions and variations from the ordinary cotton process are given. A general discussion of the growing of jute, its uses, retting and chem. compn. is included.

RUBY K. WORNER

Peroxides for textile bleaching. Their past, present and probable future. H. G. SMOLENS. *Am. Dyestuff Rept.* 17, 672–4, 678 (1928).—Bleaching with Cl and with peroxides are compared especially with reference to the recently developed electrolytic 100 vol. H_2O_2 soln. Although the chem. cost of peroxide is higher than that of Cl, the use of the 100 vol. peroxide is easier, safer and healthier to apply to cotton as compared with any form of Cl. Also, the 100 vol. peroxide bleach is followed by less shrinkage and less loss of wt. Its advantages tend to overcome the greater chem. cost. The Na_2O_2 bleach is not recommended.

Textile research—its aims and application in industry. J. H. LESTER. *Wool Record* 33, 458–61 (1928).

RUBY K. WORNER

The American Association of Textile Chemists and Colorists. E. H. KILLHEFFER. *Proc. Am. Assoc. Textile Chem. Colorists* 1928, 243–5; *Am. Dyestuff Rept.* 17, 663–5.—An address on the objects, scope and accomplishments of the Assoc., with suggestions for future work, was given by the President.

L. W. RIGGS

The spectroscope in the textile industry. RICHARD CAMERON. *Textile Colorist* 50, 182–3 (1928).—The spectroscope may be used to detect traces of impurities too

small to be detected by the usual chem. tests, for qual. tests for mordants, to trace the source of fabric samples (from traces of elements present), etc. CHAS. E. MULLIN

Single texture proofing. E. P. RYDINGS. *Trans. Inst. Rubber Industry* 4, 161-9 (1928).—A review and discussion of the methods of manuf., including the general process, wet and dry mixing, spreading, chalking, cold curing, sweetening and the influence of the quality of fabric. A general discussion follows the paper. C. C. DAVIS

Paints and their uses in the textile industry. J. J. GLICK. *Textile Colorist* 50, 693-5(1928).—The surfaces to which paints and varnishes are applied and the selection and application of the different types of finishes are considered. RUBY K. WORNER

The testing of yarns for count. H. MALDWYN WILLIAMS. *Wool Record* 33, 516-9 (1928).—A discussion of the limitations of the methods for accurate results. The measurement of a definite length of yarn is affected chiefly by the tension and also by the twist. Methods are described for the detn. of yarn no. for short lengths, as in pattern analysis and for longer lengths when several yards of material are available. RUBY K. WORNER

Recent and coming developments in machines for testing fibers, yarns and fabrics. DAVID C. SCOTT. Henry L. Scott Co., Providence, R. I. *Textile World* 74, 2623-7 (1928).—Tensile strength testing machines designed for tire cord, rubber and wire are described and their possible application to textile investigations is discussed. A new cord testing machine has a double capacity head and a recorder so arranged as to magnify the chart line in the stretch direction. A rubber testing machine has a compensating device for variations in thickness, so that the results are obtained as of one standard dimension. A machine with a compensating device for moisture variations is about to be marketed. The "flexing machine" developed by the U. S. Rubber Co. is described and is recommended for studying the effect of weave of fabric. RUBY K. WORNER

The distribution of twist. Its effect upon testing methods. H. MALDWYN WILLIAMS. *Wool Record* 33, 706-9(1928).—The degree of twist in any yarn is governed by the length of the fiber, the diam. of the thread, and the purpose for which the yarn is intended. Small lengths, however, show great variation. Although the variation of twist is largely conditioned by the spinning process, a rubbing action by the guides in many other processes, particularly those of winding, will cause an irregular distribution of twist. Methods of measuring twist are described. RUBY K. WORNER

Some recent advances in the control of plain, Chase and Schreiner calenders. JAMES A. CAMPBELL. *Textile World* 74, 2499-501(1928).—The principles, design and methods of operating the machines and their production at the present time are compared with those in 1910. The survey shows that the fundamental principles are the same, but there is a definite advance in design; that calendering is a science, not an "art," that facts are being substituted for beliefs; that continuous processes are replacing intermittent ones; and that scientific control makes possible definite schedules, increased wages, and decreased cost of production. RUBY K. WORNER

A new reagent for the detection of oxycellulose. W. F. A. ERMEN. *J. Soc. Dyers Colourists* 44, 303-5(1928).—Soln. (A) contains $\text{Fe}_2(\text{SO}_4)_3$ 20 g., $(\text{NH}_4)_2\text{SO}_4$ 25 g. and H_2O up to 100 cc. Soln. (B) contains $\text{K}_3\text{Fe}(\text{CN})_6$ 33 g. in H_2O up to 100 cc. These solns. are quite stable in the dark. To perform the test, add 5 cc. of each soln. (A) and (B) to 250 cc. of water, bring to the boil, remove the flame and immerse the cotton to be examd. for 1 min. Remove the sample and rinse, first in dil. H_2SO_4 and then in water. Any oxycellulose present will be stained a deep blue. All bleached cotton appears to react to a slight extent with this reagent, so that the ground is never quite white. The coloring matter of unbleached cotton also exerts a certain amt. of reduction on the ferric ferriyanide and raw cotton is consequently tinted a much deeper shade than well-bleached cotton, but not enough to destroy the value of the test. This reagent stains wood pulp or papers a dark blue, while pure cotton or linen papers are almost unaffected. Tannins should be fixed or removed before applying the test. L. W. RIGGS

Natural impurities in wool. "TEX." *Wool Record* 33, 575, 590(1928).—Modern methods of treatment are reviewed. RUBY K. WORNER

The practice and science of wool scouring. JOHN R. HIND. *Wool Record* 34, 921-5, 987, 993(1928).—A general article on wool scouring, dealing with the kinds of impurities to be removed, the mech. operations involved and the compn. of the scouring solns. RUBY K. WORNER

Wool drying on an entirely new principle. ANON. *Textile J. Australia* 2, 664-6(1928).—Describing the "Turblex" conveyor type of drying tunnel for wool. CHAS. E. MULLIN

Leonils in the wool industry. CHARLES GEORGE. *Textile J. Australia* 3, 254-6

(1928).—The uses of Leonil LE, S, SB and SBS in washing slubbing and piece goods, in milling and carbonizing, and in prepreg. softeners are discussed. C. E. M.

Greasy wool to yarn. WILMAB. *Textile J. Australia* 3, 205-6(1928).—Wool scouring in Australia is described. CHAS. E. MULLIN

Paint-free noils and wool. CHAS. E. MULLIN. *Textile J. Australia* 3, 14-6 (1928).—Discussing the origin and removal of paint, tar and pitch from wool and noils, and the uses and advantages of "defect-free" stocks. CHAS. E. MULLIN

Action of the alkalis upon wool. CHAS. E. MULLIN. *Am. Dyestuff Rept.* 17, 109-14, 209-14, 228, 345-8(1928).—A review and discussion of the action of various alkalis on the wool fiber. L. W. RIGGS

The valuation of protective agents. H. BLACKSHAW. *J. Soc. Dyers Colourists* 44, 297-300 (1928).—The term protective agent is generally used to define those products which protect animal fibers against the action of alkali. The most important application of such agents is in the protection of wool when dyeing with vat colors by means of the caustic soda hyposulfite vat. Sulfite cellulose liquors, synthetic tannins and formaldehyde-urea compds. are claimed to possess this protective property (cf. Edge, C. A. 16, 3213). Directions are given for making tests of protective agents, the results being checked by detns. of tensile strength, elasticity of the fiber and its microscopical appearance. Since wool treated with alkali has a greatly increased affinity for acid dyestuffs, its readiness to stain with Acid Scarlet 4R Extra (B. D. C.) affords a qual. indication of alkali treatment. L. W. RIGGS

The processing of Schappe. FRED GROVE-PALMER. *Am. Dyestuff Rept.* 17, 623-6(1928).—Schappe or "spun silk" is obtained from imperfect cocoons from which on account of some damage, the fiber cannot be reeled in a continuous thread. The work of collecting, degumming and washing Schappe is described. L. W. RIGGS

Advances in reclaiming tin from silk weighting washings. GIBSON BUTTFIELD. *Chem. Met. Eng.* 35, 607(1928).—In the customary processes for recovering Sn from silk weighted by the SnCl_4 method, the Sn losses have been as high as 16 to 75 mg. of Sn/l. of wash water, in addn. to other losses. By the Buttfeld process the Sn-bearing soln. leaving the washing machines is neutralized by automatic and continuous addn. of $\text{Ca}(\text{OH})_2$ slurry, and the solids are then settled in a Dorr thickener. The sludge is pumped to an overhead storage tank, flows thence by gravity to a spray drier where it is dried instantaneously, and then is delivered to bags or barrels. Sn losses have been reduced to approx. 4 mg./l. of wash water, drying cost is reduced 50%, and total operating costs to about $\frac{1}{3}$ of the original. W. C. EBAUGH

Artificial silk hat fibers. JAMES SCOTT. *Silk J.* 4, No. 45, 57-9(1928).—A discussion of the microscopic characteristics of visca and monofil of the Courtaulds Company. CHAS. E. MULLIN

Fine cupra-ammonium filaments. FRED GROVE-PALMER. *Rayon J.* 3, No. 1, 16-7 (1928).—A general description of the development of fine filaments. C. E. M.

Delustering rayon. CHAS. E. MULLIN AND ROSS M. STRIBLING. *Textile Colorist* 50, 377-80(1928).—The various methods of delustering, such as in the process of manuf., by pptn. in the fiber, and by alteration of the fiber surface, are discussed and the literature is reviewed. CHAS. E. MULLIN

Better sizing of rayon warps is done with new equipment and materials. HERBERT C. ROBERTS. *Textile World* 74, 1973-5(1928).—General, dealing with the materials used for sizing rayon and with the methods of application. RUBY K. WORNER

The rayon spinning process. KEMPF. *Rayon J.* 3, No. 1, 20-24(1928); cf. C. A. 22, 1690.—A discussion of the micelle structure of rayon. CHAS. E. MULLIN

Making rayon yarn hollow for stockings. FRED GROVE-PALMER. *Textile Colorist* 50, 666-7(1928).—The new hollow yarn, "Celta," is lighter in weight and has greater covering power than ordinary rayon. It resembles wool in softness, as well as possessing a comparable feeling of warmth and comfort. It is a French product, but is also being made in England. RUBY K. WORNER

Mercerizing from the gray. THOMAS F. HUGHES. *Textile Colorist* 50, 682-3 (1928); cf. C. A. 22, 1856.—A procedure is described for removing the extraneous matter and leaving the cotton piece goods in a good absorbent state to receive the mercerizing from the gray. RUBY K. WORNER

Mercerization of cotton with sulfuric acid. W. B. SELLARS AND F. C. VILBRANDT. *Am. Dyestuff Rept.* 17, 645-9, 685-95(1928).—The theory and the practice of mercerization are reviewed with more than 40 references to the literature. Concns. of H_2SO_4 below 60% cannot be used for obtaining an improved luster in cotton yarn. A mercerized product may be obtained by using concns. of 60 to 65% H_2SO_4 if tension is applied during immersion in the acid; no improvement results without tension. The

acid concn. should be kept const. to obtain uniform results. 'Concns. above 65% show less mercerization than 60 to 65%; concns. above 70% immediately attack and dissolve the cotton. The time of immersion in the acid should be from 0.5 to 2 min. Longer periods of immersion give a harsh feeling or a parchimentized product. Temps. of 0° to 30° can be used to secure improved luster. Temps. above 30° tend to weaken the cotton and decrease its luster. It is possible that temps. of -10° to -20° would give even better results. In this study the max. effect was obtained at 0° to 20°. Tensile strength and extensibility were increased only with concns. of 62.5 to 65% of H₂SO₄. Lower concns. affect the strength only slightly at ordinary temps.; at higher concns. the cotton is much weakened. Concns. of 60 to 70% H₂SO₄ increase the affinity of cotton for direct dyes. It should be possible to increase both affinity for dyes and strength by using temps. below 0° with these concns. of acid. Increase of strength and dye affinity result either with or without tension, but use of tension gives a slightly stronger product. The affinity of the dye is independent of the use of tension in the mercerization. With concns. of 60 to 70% H₂SO₄ and without tension, a shrinkage in length occurs which increases rapidly with increasing time of immersion. If treated with tension an increase of about 4% results, as compared with 30% shrinkage without tension. H₂SO₄ of 62.5% concn. shows a max. activity with cotton, affecting all its properties more at this concn. than at any other. L. W. RIGGS

Preparation for and bleaching of cotton piece goods. JAMES FITZGERALD. *Textile Colorist* 50, 685-7(1928).—A description of the procedures for singeing, steeping, boiling-off and bleaching. Recipes are given for kier liquors. RUBY K. WORNER

Novel method of increasing the affinity of cotton and other fibers for coloring matters. G. E. HOLDEN. *J. Soc. Dyers Colourists* 44, 305-7(1928); cf. C. A. 21, 2803.—The application of gelatin for increasing the affinity of cotton and other fibers for coloring material consists in immersing or padding the fiber with a hot 5 to 20% aq. soln. of gelatin, steaming for 1 hr. at 5 lbs. pressure and washing. The effects of the gelatin treatment in particular cases are described. L. W. RIGGS

Influence of heat on the affinity of cotton for dyestuffs. C. K. PATEL. *J. Soc. Dyers Colourists* 44, 301-3(1928); cf. Knecht and Muller, C. A. 19, 1315.—Cotton on heating at 150° for a long time or at higher temps. for a short time possesses a lower affinity for dyestuffs of the direct and basic classes. Tests with the direct colors Chlorazol Sky Blue FF and Benzopurpurine 4B indicated that the loss of affinity for the dyestuffs was progressive. The longer the time of heating, the less the affinity of the cotton for dyestuffs. With the basic dyestuff Methylene Blue, the loss of affinity of cotton for the color on heating was very marked up to a certain stage of time and temp., after which the effect was comparatively small. L. W. RIGGS

Finishing mohair plush. W. KEGEL. *Wollen und Leinen Industrie; Wool Record* 34, 919(1928); cf. C. A. 22, 4830.—Descriptive. RUBY K. WORNER

A machine for laboratory washing tests. WM. D. APPEL, WM. C. SMITH AND HUGH CHRISTISON. Bureau of Standards and Arlington Mills. *Am. Dyestuff Rept.* 17, 679-83(1928).—The authors present the following abstract: Coöperative work by the Am. Assoc. Textile Chem. Colorists and the Bureau of Standards has resulted in a practical machine for testing the fastness to washing of dyed textiles. With it one man may test up to 20 samples simultaneously and in a brief run obtain results similar to those obtained in com. laundry practice. It is also suitable for testing detergents, for dry-cleaning tests and for lab. dyeing. The machine is described and general specifications for it and for a standard washing procedure are given. The machine is being manufactured and may be obtained through the Assoc. L. W. RIGGS

Damage caused by mildew. Effects of temperature and moisture. FOSTER PICKLES. *Wool Record* 33, 1085-7(1928).—Instances of stain and defects in yarn and cloth traced to mildew are cited. These observations and further expts. indicate that mildew is a result of a combination of conditions of air, warmth and moisture. To prevent its development, material should be stored unconditioned in a fairly dry atm. Yarn to be exported should be shipped unconditioned in as dry a state as possible and with a frank understanding between buyer and seller. RUBY K. WORNER

Dyes from *Pistachio* trees (MELL) 29. Examination of oleins by thiocyanate (KAUFMANN) 27. Soaps in modern textile processing (DANN) 27. A diphenylpyridyl-methane dyestuff (PLAZEK, SUCHARDA) 10. Waterproofing and coating fabrics (Brit. 286,396) 18.

Dye. CARL METTLER (to J. R. Geigy A.-G.). U. S. 1,689,739, Oct. 30. A mordant dye is made by diazotizing aniline-methylene-*o*-cresotinic acid and coupling with 1(2-chloro-5-sulphophenyl)-3-methyl-5-pyrazolone, which in the form of its Na salt is a yellow powder easily sol. in hot water and which dyes wool from an HOAc bath greenish yellow tints which by chroming change more to yellow. Similar dyes also may be formed from closely related starting materials.

Dyes. CARL METTLER (to J. R. Geigy A.-G.). U. S. 1,689,740, Oct. 30. A mordant dyes is made by diazotizing *o*-toluidine-methylene-*o*-cresotinic acid and coupling with 1-naphthol-3, 6-disulfonic acid, which produces red tints on wool from an HOAc bath and also gives red tints when printed on cotton with a Cr salt. Similar dyes are obtained from other similar starting materials.

Dyes. R. F. THOMSON, J. THOMAS and SCOTTISH DYES, LTD. Brit. 286,323, Sept. 24, 1926. The halogenated dibenzanthrones prep'd. as described in Brit. 278,834 (C. A. 22, 2845) and halogenated to at least the dichloro stage are condensed with glycols. Dyes are thus formed which dye cotton blue or reddish blue shades from the vat.

Dyes. I. G. FARBENIND. A.-G. Brit. 286,005, Nov. 27, 1926. Indophenols are made by the simultaneous oxidation of 2,3-dihydroindole or a substitution deriv. and *p*-aminophenol or by condensing the former with quinone chlorimide or with *p*-nitrosophenol. Several examples are given. Sulfuretted dyes are made by subjecting the indophenols or leuco-indophenols, thus obtained, to polysulfide fusion.

Dyes. I. G. FARBENIND. A.-G. Brit. 286,226, Feb. 28, 1927. Disazo dyes yielding fast yellow shades on cotton, "viscose silk" or "cuprammonia silk" are made by coupling a sulfonic acid of tetrazotized 4, 4'-diaminodiphenylurea or a deriv. with a sulfonic acid of an acetoacetic arylide and sulfonating the product by treating with phosgene a sulfonic acid of a *p*-aminosulphophenyl-azo-acetoacetic arylide. Several examples are given.

Dyes. I. G. FARBENIND. A.-G. Brit. 286,359, Dec. 1, 1926. Indigoid dyes are made by condensing 8-halogen-1,2-naphthhisatins, which may contain further substituents such as Cl, Br or NO₂, or their α -derivs., with the usual indigoid dye components such as hydroxythionaphthene, oxindole, indoxyl, acenaphthene, α -anthrol, α -hydroxyanthranol, α -naphthol or carbazole. The products, which may be further halogenated, dye from the vat in blue-gray, violet, olive and other shades. Several examples are given.

Dyes. I. G. FARBENIND. A. G. Fr. 638,138, July 22, 1927. Yellow shades are produced on esters or ethers of cellulose, by dyeing the fibers with mono-sulfonated arylazodiarylamines, contg. at least 1 nitro group in the diarylamine complex. Examples of dyes are 4-benzeneazo-2',6'-dinitro-4'-sulfodiphenylamine and 4-benzeneazo-4'-nitro-2'-sulfodiphenylamine.

Dyes. I. G. FARBENIND. A.-G. Fr. 638,190, July 25, 1927. New vat dyes of the anthraquinone series which contain one or more oxazolic groups substituted in the μ C by an anthraquinone group are prep'd. by heating *o*-aminohydroxyanthraquinones in the presence or absence of solvents with anthraquinone-aldehydes or substances capable of yielding them during the reaction, or other anthraquinone derivs. having aldehyde character, or by condensing by heating the anthraquinonecarbonylaminoanthraquinones negatively substituted or contg. an OH group *o*- to the amino group. In examples, (1) 2, 3-aminohydroxyanthraquinone is heated to 250° with anthraquinone-2-aldehyde. The product dyes cotton clear yellow from the vat. (2) 3-Aminoalizarin is boiled with 1-aminoanthraquinone-2-aldehyde in PhNO₂. The product dyes cotton a full red. Several other examples are given.

Azo dyes. I. G. FARBENIND. A.-G. Brit. 286,227, Feb. 28, 1927. Disazo dyes are made by diazotizing an aminoazo dye derived from an arylene diamine carboxylic acid and coupling with a component, and trisazo dyes are made by tetrazotizing a di-aminoazo dye and coupling with a component; the coupling is preferably effected in the presence of a tertiary base, and the dyes formed may be aftertreated with metallic salts in substance or on the fiber. Those contg. free NH₂ groups may be diazotized and coupled on the fiber. Several examples are given of the production of dyes giving black, violet and blue shades, and of aftertreatment with Cu and Cr salts.

Azo dyes. I. G. FARBENIND. A.-G. Brit. 286,274, March 2, 1927. Monoazo dyes giving blue to violet shades are obtained by coupling a diazotized 4-amino-diphenylamine contg. one or more alkyl, alkyloxy or halogen groups with an arylide of 2,3-hydroxynaphthoic acid. Several examples are given, and the dye may be formed on the fiber.

Azo dyes. I. G. FARBENIND. A.-G. Brit. 285,812, Feb. 21, 1927. Disazo dyes are made either by coupling 1 mol. of a tetrazotized diamine contg. carboxyl groups in

o-position to the amino groups (e. g., tetrazotized 4,4'-diaminodiphenylurea-3,3'-dicarboxylic acid) with 2 mols. of acetoacet-*o*-chloranilidesulfonic acid or other suitable acetacetarylidesulfonic acid, or by coupling 1 mol. of a diazotized amine contg. a carboxyl group in *o*-position to the amino group with 1 mol. of an acetoacetarylidesulfonic acid and converting the resulting monoazo dye into a disazo dye, e. g., by treatment with phosgene, thiophosgene or CS₂. The products dye cotton or "viscose silk" clear yellow, orange and brown shades fast to light and may be aftertreated with metallic salts. Several examples are given.

Azo dyes. I. G. FARBENIND. A.-G. Fr. 638,408, July 28, 1927. Any diazo

compd. is coupled with aminonaphthols of the formula HO-R-N⁺-YX, in which Y represents a carboxylic acid ester, R a naphthalene ring substituted or not, X a H atom or alkyl, aryl or aralkyl group. In examples, the compd. obtained by the action of chloroformic ethyl ester on Na 2-amino-8-naphthol-6-sulfonate is coupled with diazotized *p*-aminomethylacetanilide, and the compd. obtained by the action of chloroformic ethyl ester on Na 1-amino-8-naphthol-3,6-disulfonate is coupled with *m*-xylydine, giving a dye which dyes wool reddish blue fast to light. The products may be used to manuf. dis- and poly-azo dyes.

Azo dyes. I. G. FARBENIND. A.-G. Fr. 32,804, Nov. 19, 1926. Addn. to 606,519.

Azo dyes are prepd. from coupling components, one or both of which contain one or more carboxylic acid ester groups, not including as coupling components esters of pyrazolonesulfocarboxylic acid or the prepn. of dyes starting with esters of 4-nitro-2-diazobenzoic acid and arylides of 2-hydroxynaphthalene-3-carboxylic acid. Several examples are given.

Azo dyes and intermediates. J. R. GEIGY, SOC. ANON. Fr. 637,867, July 18, 1927. Mono azo dyes are obtained by diazotizing an aminosulfobenzoic acid having the sulfo group in the *o*-position to the amino group, and coupling with a usual coupling component. In examples, 2-chloro-5-amino-4-sulfobenzoic acid is diazotized and coupled (1) with β -naphthol, the product giving a Ca or Ba lake of bright red tint faster to light than lake red C and (2) with 2,8,6-aminonaphtholsulfonic acid, giving a product which dyes wool in a H₂SO₄ bath vivid bluish red tints fast to light. The fastness can be increased by after-chroming. By using pyrazolones as coupling components, dye-stuffs giving greenish or yellow tints, very fast to light, are obtained. 2-Chloro-5-amino-4-sulfobenzoic acid is made by oxidizing *o*-chloro-*p*-toluenesulfonic acid, nitrating and reducing. 2-Chloro-4-amino-5-sulfobenzoic acid is made by sulfonating *o*-chloro-*p*-nitrotoluene, oxidizing to the carboxylic acid and reducing the nitro group.

Monoazo dyes from pyrazolones and aminobenzenepolysulfonic acids. LEON W. GELLER (to National Aniline & Chemical Co.). U. S. 1,688,044, Oct. 16. Azo dyes are prepd. by coupling a diazotized aniline poly-(preferably di-)sulfonic acid with a 1-aryl-5-pyrazolone compd. of the benzene or naphthalene or other aromatic series which may contain substituents in the aryl radical. The dyes thus formed dye wool yellow to red to brown shades. Examples are given.

Monoazo dyes from disulfonaphthylpyrazolones and *o*-aminohydroxybenzenes. LEON W. GELLER (to National Aniline & Chemical Co.). U. S. 1,688,045, Oct. 16. A 1-(4',8'-disulfo-2'-naphthyl)-5-pyrazolone compd. (e. g., the 3-methyl deriv.) is coupled with a diazotized *o*-amino-phenol compd. or a homologue or nuclear substitution product which contains an acid group such as a carboxyl or sulfonic acid group or both. The dyes thus formed dye wool in an acid bath yellow to red to brown shades which change on after-chroming to yellow-red to blue-red tints. Examples are given.

Azine dyes. SOC. ANON. DES MATIÈRES COLORANTES ET PRODUITS CHIMIQUES DE ST.-DENNIS, R. LANTZ and A. WAHL. Brit. 285,840, Feb. 22, 1927. Oxazine dyes are converted into *meso*-arylazine dyes by treatment with arylamines, e. g., phenylimino- β -, α , β' , α' -symmetrical dinaphthoxazine is treated with aniline, *p*- or *o*-toluidine, anisidine or *p*-phenylenediamine. Other examples also are given.

Dibenzanthrone dyes. I. G. FARBENIND. A.-G. Fr. 32,811, Dec. 29, 1926. Addn. to 581,915. Vat dyes are prepd. by treating ethers of hydroxybenzanthronyls with alk. condensing agents. E. g., a dye of greater purity than that in the 1st. example of 581,915 is obtained from Bz2-Bz2'-dimethoxy-Bz1-Bz1'-dibenzanthronyl which is prepd. from Bz1-iodo-Bz2-methoxybenzanthrone.

Vat dye. BRITISH DYESTUFFS CORPORATION, LTD., and ANTHONY JAMES HAILWOOD. Fr. 638,387, July 28, 1927. The dye prepd. by fusing naphthalimide in NaOH at a temp. of 280-300° is made sol. by treating it with oleum, SO₃ or chlorosulfonic acid and pouring the mixt. into water or ice.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 636,345, May 28, 1925. Vat dyes

are prep'd. by converting into the corresponding hydroxynaphthenes the 3,5-dimethyl-4-halogenphenyl-, or the 3,4-dimethyl-5-halogenphenyl-1-thioglycollic acids or their derivs. substituted in the 2 position by a nitrile, CONH_2 or carboxyl group, and by transforming the hydroxythionaphthenes by oxidation into symmetrical dyes of the thioindigo series or by condensing the hydroxythionaphthenes or their 2-derivs. with compds. capable of coupling therewith. Examples are given of dyes giving reddish blue, violet-red and violet shades on cotton.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 636,370, June 21, 1927. New vat dyes are prep'd. by treating with acid condensing agents, the 2-benzanthronyl-1-aminoanthraquinones, which are obtained by condensing 1-aminoanthraquinones with 2-halogenbenzanthrone. Examples are given of dyes which give brown and browning-red shades on all vegetable fibers.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 32,810, Dec. 18, 1926. Addn. to 584,237. New vat dyes contg. S are prep'd. by combining hydroxythionaphthenes acylated in the OH group of the thionaphthene ring (prep'd. by condensing arylthioglycolcarboxylic acids by means of Ac_2O) with cyclic diketones in general, *e. g.*, with isatins or 2,3-diketodihydrothionaphthene or their derivs. capable of reacting in the same sense. Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 32,850, July 31, 1926. Addn. to 625,272. Further examples of violet vat dyes of the 2-thionaphthene-2-indolindigo series prep'd. according to 625,272 are given. Thus, a dye giving bluish violet colors on cotton from the vat is prep'd. by suspending 4-methyl-5,7-dichlorohydroxythionaphthene in chlorobenzene and adding 5,7-dichloro- α -isatin chloride (from 5,7-dichloroisatin and P_2Cl_5 in chlorobenzene) or 5,7-dichloro- α -isatinyride. 4-Methyl-5,6,7-trichloro-, 4-ethyl-5,7-dichloro-, or 4,7-dimethyl-5-chlorohydroxythionaphthene may also be used as starting materials.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 638,022, July 20, 1927. Vat dyes are prep'd. by heating acylated 2-halogenpyrazolanthrone or other cyclic *meso*anthrone derivs. from 1-aminoanthraquinone substituted in the 2 positions by halogen, with metals or agents having a similar action or treating, if necessary, the resulting products with saponif. agents. *E. g.*, (1) acetyl-2-bromopyrazolanthrone is heated in naphthalene in the presence of Cu to 230–250°, and the product saponif., giving the dye described in Fr. 451,093; (2) the Me ether of 2-bromoanthrapyrimidine similarly heated gives a product which dyes cotton brownish red from the vat; (3) 2-iodomethylanthrapyrimidine (by decompn. of 2-diazomethylanthrapyrimidine with KI) forms a product which gives a clear citron yellow; and (4) 2-iodoceramidonine (by treating 1-anilino-2-iodoanthraquinone with H_2SO_4) gives a product which gives a brown-red.

Reduction of vat dyes and like compounds. I. G. FARBENIND. A.-G. Fr. 636,223, June 18, 1927. Vat dyes and compds. contg. groups reducible in like manner are reduced by a mixt. of SO_2 and formic acid in the presence of org. bases but in the absence of any appreciable quantity of water, and with or without diluents. The products may be acylated during or after reduction. Examples are given of the reduction of indigo, thioindigo, tetrabromindigo and dimethoxydibenzanthrone.

Fixing dyes. I. G. FARBENIND. A.-G. Fr. 636,548, June 24, 1927. Acid or basic dyes are fixed on the fiber by treating the fiber before dyeing with reduction products of complex compds. of either tungstic or molybdic acid or both. The reduction may be effected with bisulfite, hyposulfite or formaldehyde. *E. g.*, cotton is sat'd. with a 10% soln. of phosphotungstic acid, phosphomolybdic acid or the two, and treated with NaHSO_3 and H_2SO_4 . The fiber may then be dyed, *e. g.*, with Chinese green.

Dye composition. ALBERT DAVID (to Dip-It, Inc.). U. S. 1,687,751, Oct. 16. A dye is used with a pure neutral soap, a liquid carrier such as water and sufficient of a hygroscopic substance such as glycerol substantially to prevent caking of the mixt. on exposure to the air. The compn. is suitable for use on mixing with addnl. water.

1-Amino-4-pentamethyleneamineanthraquinone-2-sulfonic acid. KLAUS WEIN-AND (to Grasselli Dyestuff Corp.). U. S. 1,688,256, Oct. 16. This compd. may be made by heating an aq. soln. of 1-amino-4-bromo-2-anthraquinonesulfonic acid with pentamethyleneamine and CuSO_4 . It crystallizes in blue needles, sol. in water with a blue coloration and dyes wool pure fast blue shades. Bornylamine yields a corresponding deriv.

Condensation products of the benzanthrone series. I. G. FARBENIND. A.-G. Fr. 32,788, Dec. 30, 1926. Addn. to 612,367. Bz-2-aroylhydroxybenzanthrone is treated with acid condensing agents to obtain hydroxydibenzpyrenequinones which are then alkylated. Thus, by condensing Bz-2-benzoylhydroxybenzanthrone with AlCl_3 and NaCl, a product, 1-hydroxy-3,4,8,9-dibenzpyrenequinone, is obtained which

dyes cotton a brown-red from the vat. If the product is alkylated dyes are obtained which dye cotton yellow shades from the vat.

Condensation products of the benzanthrone series. I. G. FARBENIND. A.-G. Fr. 636,268, June 20, 1927. New condensation products are obtained by treating Bz-1-nitro-2-methylbenzanthrone with acid condensing agents such as fuming H_2SO_4 , chlorosulfonic acid or $AlCl_3$ with or without a solvent or indifferent diluent. The products give vat dyes which dye cotton from green to grayish blue or black, and they form intermediates for other dyes. A dye product can be obtained by treating the crude product with org. solvents and is probably an inner anhydride of Bz-1-aminobenzanthrone-2-carboxylic acid, or the free acid may be obtained by treating the crude product with dil. alkali carbonate and acidifying.

Transformation products of cyannaphthalenesulfonic acid. I. G. FARBENIND. A.-G. Fr. 636,489, June 23, 1927. Cyannaphthalenesulfonic acids having at least one sulfonic group *o*- or *p*- to the CN group are converted by means of alkali with or without mineral or org. diluents into compds. having the general formula $OY-C_8X-Z$, where the OY group is *o*- or *p*- with respect to the Z group, X represents H, one or more of which may be replaced by a univalent substituent, Y represents H or an alkyl group, and Z denotes CN, $CONH_2$ or $COOH$. Compds. contg. the CN group are obtained by a moderate treatment, such as by NaOH with an inert diluent. Compds. contg. the $COOH$ group are obtained by a treatment with caustic alkalies at a temp. of $150-250^\circ$ or by sapon. of compds. contg. the CN group. Compds. contg. the $CONH_2$ group are obtained by a treatment with caustic alkalies in the presence of an alc. at a temp. of $80-150^\circ$. The compds. are used for the prepn. of dyes.

Dyeing cellulose derivatives. HENRY DREYFUS. Fr. 32,813, Jan. 4, 1927. Addn. to 627,071. Materials contg. cellulose acetate or other org. deriv. of cellulose are dyed, printed or stenciled by compds. contg. an aryl dye nucleus coupled by one or more O or S atoms with one or more aliphatic side chains contg. one or more hydroxyl groups. The dyes may be applied in soln. if sol. or they may be brought into colloidal soln. in known manner. Several examples of dyes and the method of obtaining them are given.

Dyeing cellulose esters. BRITISH CELANESE, LTD., and H. C. OLPIN. Brit. 285,641, Feb. 9, 1927. Materials contg. cellulose acetate, formate, propionate, butyrate or the products obtained by treating alkylized cellulose with sulfochlorides such as *p*-toluene sulfochloride, or ethers such as methyl, ethyl or benzyl cellulose, or condensation products of cellulose and glycols or other polyhydric alcs. are dyed, printed or stenciled by use of sulfuric esters of anthraquinonylamino alcs. or of substituted anthraquinonylamino alcs. or alkali metal salts or other suitable salts of such esters. Numerous examples are given.

Dyeing cellulose esters and ethers. H. DREYFUS. Brit. 285,942, Oct. 23, 1926. Material comprising cellulose acetate, formate, propionate, butyrate or other cellulose ester or ether is dyed, printed or stenciled by treatment with a swelling agent for the cellulose deriv. and then dyeing or coloring with an aq. dispersion of an insol. or relatively insol. org. coloring matter dispersed by various specified dispersing agents. A large no. of examples of substances suitable for use as swelling and dispersing agents are given.

Dyeing cellulose esters and ethers. H. DREYFUS. Brit. 285,948, Nov. 12, 1926. Yarns, threads or fabrics contg. cellulose acetate or other cellulose esters or ethers are rendered amenable to mordanting by preliminary treatment with swelling agents such as formic, lactic, acetic or glycolic acids, EtOH, acetone, diacetone alc., diacetin, phenolic compds., thiocyanates, cyanates, isocyanates, isothiocyanates, urea, urethans, thiourea, thiourethans, guanidine and their alkyl and aryl substitution products. Mordant salts such as Fe chloride or nitrate or $SnCl_2$ or Cr or Al compds. may be used and if temps. above $75-80^\circ$ are used protective salts or agents must be added to avoid delustering. Several examples are given for dyeing cellulose acetate.

Dyeing cellulose esters and ethers. H. DREYFUS. Brit. 285,968, Nov. 23, 1926. Org. substitution products of cellulose such as the formate, acetate, propionate, or butyrate, "immunized cotton," or cellulose ethers, are dyed, printed, stenciled or otherwise colored with compds. in which an aryl dye nucleus (other than an azo dye nucleus) contains either in the nucleus or as a substituent an amino or imino group one or more H atoms of which are replaced by an aliphatic side chain contg. OH but not $COOH$. The use of 1-(β -hydroxyethyl)-aminoanthraquinone (solubilized with turkey red oil) with a soap bath, and many other specific examples are given. Brit. 285,969 specifies the use of dyes in which the aliphatic side chain is linked to the aryl nucleus through O

or S, e. g., anthraquinone-1- β -hydroxyethylmercaptan obtained from anthraquinone-1-mercaptan and ethylene chlorohydrin, and also gives several other examples.

Dyeing cellulose acetate or similar cellulose derivatives. HENRY C. OLSEN (to Celanese Corp. of America). U. S. 1,688,553, Oct. 23. 1- β -Hydroxyethylaminoanthraquinone sulfuric ester or other suitable sulfuric ester of an anthraquinonylamine alc. is used for dyeing. Scarlet, violet, blue-violet, pure blue and bluish red shades are obtained with different specified compds.

Dyeing artificial silk. HENRY DREYFUS. Fr. 638,249, July 26, 1927. Cellulose acetate or other artificial silk is treated before mordanting and dyeing with warm or boiling water or damp steam, protecting agents such as NaCl or Na₂SO₄ being added to the water or applied to the silk to prevent delustering.

Production of aniline black on cloth. THE CALICO PRINTERS' ASSOCIATION, LTD., LOUIS AMÉDÉE LANTZ and RONALD WATSON. Fr. 637,884, July 18, 1927. Fibers which have been impregnated or printed in the usual way with an aniline salt, an alkali chlorate and an alkali ferrocyanide are heated for a short time to a temp. of 110–180° in the absence of steam, and then to a steam treatment.

Stripping colors from fabrics. G. F. LLOYD. Australia 11,686, Feb. 11, 1928. The color of a fabric is lightened to any desired point by a treatment with water contg. the products of reaction of Na bisulfite, with Zn and a soln. obtained by treating crude coal-tar naphtha with H₂SO₄. The temp. and concn. det. the amt. of color removed.

Discharge printing on cellulose acetate. SOC. ANON POUR L'IND. CHIM. À BAËL. Brit. 285,973, Nov. 23, 1926. White or colored discharges on dyed "acetate silk" are produced by printing the material with a paste comprising a Zn sulfoxylatealdehyde compd. which may be used with an acid or alkali as required. Several examples are given.

Pattern effects on fabrics. ALBERT BODMER (to Heberlein & Co. A.-G.). U. S. 1,688,798, Oct. 23. A fabric is woven with nitrated and unnitrated threads and portions of the nitrated threads are decompd. with alkali according to a definite pattern. U. S. 1,688,799 specifies applying to a similar fabric a reserve (according to a definite design) which is resistant to the action of a reagent such as NaOH which will serve to decomp. the nitrated threads and then subjecting the unreserved portions of the fabric to the action of such reagent.

Preparing fibers for spinning. I. G. FARBENIND. A.-G. Brit. 286,302, March 4, 1927. An app. is described, for softening and kneading a continuous band of fibers.

Preparing fibers for spinning from agave, yucca, pineapples, etc. M. M. LLORENS, S. GÜELL, BARON DE GÜELL and F. BASTOS. Brit. 286,337, Nov. 3, 1926. Mech. features.

Metallizing fabrics. R. HÖLDRICH, F. NEUBER and S. LAM (to O. Trebitsch). Brit. 285,921, Feb. 26, 1927. Solns. such as those of salts of precious metals are applied to and reduced on the fabric and the coated fabric is then subjected to treatments such as pressure or friction. The fabric may be preliminarily treated with solvents such as NH₃, KCN or acid such as formic acid or dil. H₂SO₄ and colloids such as gelatin or gluten may be added to the solvent or metal salt solns.

Cellulose designs on fabrics of other material. CAMILLE DREYFUS and HERBERT PLATT (to Celanese Corp. of America). U. S. 1,689,426, Oct. 30. A design of cellulosic material such as viscose or cellulose soln. is imprinted on fabrics of other material such as those formed of silk, wool, cotton or cellulose esters or ethers.

Apparatus (with successive U-shaped compartments) for bleaching fabrics in rope form and in continuous manner. JACKSON & BRO., LTD., and C. TAYLOR. Brit. 285,689, April 23, 1927.

Preparing artificial fibers for washing, etc. ERNEST K. GLADDING (to DuPont Rayon Co.). U. S. 1,688,702, Oct. 23. A cake of artificial fibers is provided with a covering of fabric such as cheese cloth.

Nozzles for forming artificial filaments. C. L. WALKER. Brit. 286,342, Nov. 19, 1926. The method of forming nozzles described in Brit. 253,209 is modified by using (instead of capillary tubes of noble metal), flattened disks or the like which may be formed of Pt, are provided with spinning apertures, and are secured in a spinning nozzle body of other material such as porcelain or glazed Ni.

Yarn of mixed natural and artificial silk. I. G. FARBENIND. A.-G. Brit. 286,275, March 2, 1927. Mech. features of producing yarn exhibiting cross dye effects.

Weighting artificial silk. BRITISH CELANESE, LTD., H. DREYFUS and G. H. ELLIS. Brit. 285,941, Oct. 23, 1926. Yarns, threads, fabrics, films, etc., formed in whole or in part of cellulose acetate or other cellulose esters or ethers are loaded with metals such as Sn, Zn, Al, Bi and W by a modification of the process described in Brit.

281,084 (C. A. 22, 3528) in which there is employed for the loading a soln. contg. a loading metal and a thiocyanate in which the thiocyanate is in a proportion not exceeding that of the loading metal. The loading metal may be fixed with tannic acid, a phosphate or silicate or by washing with water. Examples are given.

Treating artificial silk. HENRY DREYFUS. Fr. 638,248, July 26, 1927. Cellulose acetate or other artificial silk to be weighted with insol. metallic substances is first treated with warm or boiling water or damp steam, protecting agents such as NaCl or Na_2SO_4 being added to the water or applied to the silk to prevent delustering.

Waterproofing artificial silk. J. P. BEMBERG, A.-G. Brit. 286,257, March 1, 1927. An Al soap (suitably a soap made from tallow) dissolved in an org. solvent such as trichloroethylene is used as a waterproofing agent, with or without addn. of other substances such as solid or liquid hydrocarbons, fats, fatty acids or waxes which are sol. in the solvent used.

Sodium chloride and tri-sodium phosphate composition. CHARLES F. BOOTH, ARTHUR B. GERBER and PAUL LOGUE. U. S. 1,688,112, Oct. 16. H_3PO_4 , Na_2CO_3 and NaOH combined with NaCl and water yield a compd. of NaCl and Na_3PO_4 which is suitable for use in fabric treatments.

Cottonization of textile fibers. ALBERT CHARBONNEAU. Fr. 636,184, Oct. 14, 1926. Textile fibers other than cotton such as linen, agave, and esparto are transformed into fibers resembling cotton by a succession of mech. and chem. operations to give a fiber which can be worked with the existing cotton looms. The chem. treatment consists in submitting the fibers to baths of NaOH, Na_2CO_3 and soft soap, bleaching baths, and neutralization.

Conditioning cotton. ARTHUR COBB. U. S. 1,688,524, Oct. 23. Cotton is conditioned for spinning, etc., by heating it to above 80° while being worked, in a substantially dry atm. An app. is described.

Mercerized cotton. ÉMILE LANG. Fr. 637,921, Nov. 23, 1926. Cotton is given a silky feel and look by lixiviation with soda and soap and a treatment with colloids, such as starch, flour, dextrin, glue or gelatin, and then mercerizing.

Cotton cloth with a wool finish. MORTIMER J. MACK. U. S. 1,689,208, Oct. 30. A cotton fabric is successively subjected to bleaching, dyeing, napping, mercerizing, sizing and re-brushing.

Felt. HYMAN STEIN, WILLIAM E. AUSTIN and IRVING LIEBOWITZ (to Stein Fur Dyeing Co.). U. S. 1,687,801, Oct. 16. Fibers such as those of rabbit skins are treated with a carotting agent such as Hg nitrate and with FeSO_4 or other ferrous salt which serves as a protective agent against excessive action by a bleaching agent such as H_2O_2 . U. S. 1,687,802 also relates to use of Hg and Fe compds.

Treating fabrics with sulfur to repel insects. WILLIS E. RAGAN. U. S. 1,688,597, Oct. 23. Clothing or other fabrics are treated with powd. S and heated to convert the S into thin liquid form so that it will penetrate the pores of the fabric, and the material is then cooled to convert the liquid to a fine powder.

Mothproofing fabrics. HILTON I. JONES. U. S. 1,688,717, Oct. 23. Fabrics are first treated with an aq. soln. of casein and then with an aq. soln. of a salt of a rare earth metal such as Ce, Th or La.

Moth-proofing articles. I. G. FARBENIND. AKT.-GES. Fr. 636,434, June 22, 1927. Articles are treated with moth-proofing substances in the form of a fine powder with or without the addns. of other substances such as kieselguhr, talc or sawdust.

Mothproofing upholstery, etc. I. G. FARBENIND. AKT.-GES. Brit. 285,825, Feb. 21, 1927. Wetting agents such as sulfonated fatty acids, aromatic sulfonic acids or their salts are used with mothproofing compns. such as those described in Brit. 173,536, e. g., a soln. of 4 grains per l. of Na fluosilicate and 1 grain of Na isopropyl-naphthalene-sulfonate may be used to spray furniture. Partially hydrogenated aromatic sulfonic acids (which may contain alkyl, aryl or aralkyl residues) also may be used as wetting agents.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Survey of the literature on paints and their raw material in 1927. H. WOLFF. *Chem. Umschau Fette, Oele, Wachse u. Harze* 35, 218-21, 228-32, 256-8(1928).—A review of the journal and patent literature, arranged under the following headings: (1) resins, (2) drying and driers, (3) paints, (4) nitrocellulose varnish and pigments, (5) solvents, (6) Methods of examn.

P. ESCHER

Analysis of paint materials. F. W. SMITHER, *et al.* *Proc. Am. Soc. Testing Materials* 27, Pt. 1, 410-23(1927).—This is a report of sub-committee VIII on methods of analysis of paint materials. It gives detailed descriptions of a highest accuracy sp. gr. method for pigments and a rapid method for single samples. A no. of corrections and addns. are made to the original report. Cf. *C. A.* 18, 1207. R. J. MOORE

Unreliability of visual inspection of exposure tests of paint. PERCY H. WALKER AND E. F. HICKSON. *Ind. Eng. Chem.* 20, 997(1928).—The writers have long been convinced that the rating of exposure tests on the basis of visual inspection of painting test panels or structures, with or without photographs, is very unreliable and have urged the development of quant. methods for evaluating such tests. Recently they noted a case which they quote in substantiating their view. A steel panel, painted and exposed for about 3½ yrs., appeared in an advanced state of decay and needed recoating. On vigorously washing, however, with soap and water, the panel was found in excellent condition. The panel would have been rated sound by the elec. cond. method. Cf. *C. A.* 22, 2669. R. J. MOORE

Tinting strength of pigments. H. D. BRUCE. *Bur. Standards J. of Research* 1, 125-45(1928).—A graphic method is described by which the purity and dominant wave length of a sample color are given numerical values by comparison with a block of $MgCO_3$. H. C. HAMILTON

The testing of paint films for weatherability and rust preventiveness. W. VAN WÜLLEN-SCHOLTEN. *Farbe Lack* 1928, 446-7.—Reports of exposure tests should give complete details such as the kind of metal used, manner of cleaning, time of drying of each coat, location, season of the year, abnormalities in the weather, direction of exposure, etc. The author gives a recommended scheme for prep. and conducting exposure and accelerated tests, resistance to water and smoke. G. G. SWARD

Analysis of white linseed-oil paints. R. L. HALLETT, *et al.* *Proc. Am. Soc. Testing Materials*, 27, Pt. 1, 873-94(1927).—Tentative methods are offered for the analysis of the oil and pigment. R. J. MOORE

Anti-fouling paints. A. M. MUCKENFUSS, *et al.* *Proc. Am. Soc. Testing Materials* 27, Pt. 1, 430-7(1927).—A series of tests on ships was run to det. the importance of fineness of particles using Cu oxide and Hg oxide. Conclusion: Scale Cu oxide (contg. both cuprous and cupric oxide) is about as satisfactory as the electrolytic or cuprous oxide, when both are ground to a very fine mesh. The same is true of the 2 varieties of Hg oxide. Another series of tests was run to det. the comparative value of cuprous and cupric oxides as toxics and of other chem. compds. present in the common com. toxics in use. These compds. were obtained in as pure a form as possible, analyzed, ground to 325 mesh and placed in a series of paints, all with the same vehicle and with the same % of actual Cu and Hg. The tests were confined to compds. of these 2 metals. The order of resistance to fouling was as follows, beginning with the best: (1) CuO + yellow HgO , (2) Cu_2O , (3) red HgO , (4) yellow HgO , (5) Cu cyanide + yellow HgO , (6) Cu resinate (Cu_2O) + yellow HgO , (7) Cu cyanide, (8) CuO + yellow HgO , (9) Cu_2O + yellow HgO , (10) Cu carbonate + yellow HgO , (11) Paris green + yellow HgO , (12) Cu oleate (Cu_2O) + yellow HgO , (13) Cu carbonate, (14) Cu resinate + Cu_2O , (15) Paris green, (16) Cu oleate + Cu_2O , (17) CuO . R. J. MOORE

Paint chemist and his job. DONALD DAVIDSON. *Paint, Oil, Chem. Rev.* 86, No. 16, 12-3, 25(1928).—A review of the duties that might be performed by the chemist in a paint and varnish plant. R. J. MOORE

Modern painting methods. Nitrocellulose lacquers. R. LUYA. *La Vie technique et industrielle (Paris)* 10, 529-37(1928).—The com. use in France is described. E. M. SYMMES

Some advantages of spray painting. R. C. SHEELER. *Ind. Power* 15, 56-7, 132, 135-6(1928). E. J. C.

Chinese wood oil. IV. Wood oil as a crystalloid; the autoxy-polymerization during drying. A. EIBNER AND E. ROSSMANN. *Techn. Hochsch., Munich. Chem. Umschau Fette, Oele, Wachse u. Harze* 35, 241-50(1928); cf. *C. A.* 22, 4839.—Sunlight and ultra-violet light change part of the α -eleostearin, the principal constituent of Chinese wood oil, rapidly into the cryst. β -eleostearin, m. 61°; dispersed daylight changes it slowly and no change or a very slow change occurs in the dark. These β crystals can be seen under the microscope in polarized light at 0°, but at room temp. the crystals redissolve in the oil up to 10%. The change from the α to the β form is the first step in the drying process of Chinese wood oil. The next step is the conversion of the crystals into a film under the influence of light, heat and O_2 . The opt. conditions for rapid drying are: intense light (sunlight), high temp. (70°) and presence of O_2 . The crystals absorb O_2 up to 12%, become insol., disperse, do not melt, and their acids have mol. wts.

of 380-400, indicating polymerization. The polymerized insol. product forms with the still unchanged oil an apparently finished film, and its final unexplored phase is the gradual filming of α -eleostearin. P. ESCHER

Insulating varnishes and drying of varnishes. R. SCHWARZ AND FR. SCHRÖDER. *Farbe Lack* 1928, 425, 436, 451-2.—The principal materials used in the prepn. of insulating coatings are oil varnishes, asphalt varnishes and cellulose lacquers. A few typical formulas are given. "Zellon" (cellulose acetate) lacquers contg. one or more of the following, oils, resins, tar, wax, etc., yield films which have a resistance of 21,000-26,000 megohms per cm. and a breakdown voltage of 13,000 v. at 0.2 mm. thickness. G. G. SWARD

Sampling and testing lacquer solvents and diluents. WAYNE R. FULLER, *et al.* *Proc. Am. Soc. Testing Materials* 27, Pt. 1, 870-2(1927).—Tentative methods are offered for sampling, sp. gr., color, distn., residue, non-volatile, residual odor, H_2O , acidity, alky., ester value, and Cu corrosion test. R. J. MOORE

Lacquer finishing small articles by the tumbling process. W. W. BENNETT. *Ind. Finishing* 4, 34, 39-40(1928). E. J. C.

Luster of lacquer finish depends on dispersion of pigments. M. J. CALLAHAN. *Automotive Industries* 59, 413-5 (1928).—Cf. C. A. 22, 3999. E. M. SYMMES

Shellac making in India. R. K. S. *Indian Textile J.* 38, 412-3(1928).—An illustrated description of the primitive but interesting methods still used in the lac industry in India. RUBY K. WORNER

Finishes. P. S. KENNEDY. *Ry. Mech. Engr.* 102, 591-3(1928).—A discussion of the defects of modern finishes and the finish of the future. E. M. SYMMES

New and unusual baked finishes for metal parts. W. J. MISKELEA. *Fuels and Furnaces* 6, 1409-12(1928).—A discussion of the use, application and baking of unique finishes such as crystallizing lacquer, crinkle japan, flake finish, plastic finish and others to wood and metal parts. E. H.

Finishing modern airplanes in color. D. O'BRIEN. *Ind. Finishing* 4, 27, 29-30 (1928). H. G.

Vinyl resins. HENRY A. GARDNER. *Am. Paint Varnish Manufs. Assoc. Circ.* No. 337, 637-65(1928).—The prepn. and certain properties of the condensation resins of vinyl alc. and chloride are reviewed with regard to their use in protective coatings. Many patents covering these resins are reprinted, showing the specific claims. R. J. M.

Specification disclosures on oil-soluble phthalic and phenolic type synthetic resins with the results of some recent exposure tests on the latter. HENRY A. GARDNER. *Am. Paint Varnish Manufs. Assoc. Circ.* No. 399, 673-709(1928).—Recent synthetic resins contg. phenol-formaldehyde and glyceryl phthalate are briefly referred to. The results of accelerated roof tests are given of 7 varnishes made from tung oil—soy oil mixts. with 2 different synthetic resins compared with like varnishes made with ester gum and with rosin. The synthetic resin varnishes gave better durability. Photomicrographs illustrate the various types of perishing shown by different varnishes. Patent references and specifications are given for many phenolic and phthalic type, condensation resins. R. J. MOORE

Paints and their uses in the textile industry (GLICK) 25. Importance of standard thermometer in the testing of materials [tung oil] (FULWEILER) 1. Hydrometallurgical laboratory [TiO_2 for pigment] (TRAILL) 9. Glycerol and its substitutes [in ink industry] (DARKE, LEWIS) 27. Finnish turpentine. VII. Isodiprene, a new terpene of the sylvestene group (ASCHAN) 10. Ozonizing mixed liquid hydrocarbons such as those obtained in cracking petroleum oils [suitable for varnish manufacture] (U. S. pat. 1,689,599) 22. Device for separating coarse particles and aggregates from finely divided pigments (U. S. pat. 1,688,307) 1. Experiments in producing cellulose ethers and esters with special reference to cellulose nitroacetate (GARDNER, KNAUSS) 23.

Water paints. BRITISH DYESTUFFS CORP., LTD., A. SHEPHERDSON and F. CHAPMAN. *Brit.* 285,929, Aug. 26, 1926. Water paints, distempers, etc., have added to them a wetting-out or dispersing agent consisting of sulfonic acids derived from CH_3O -naphthalene or CH_3O -phenol condensation products, the alkylnaphthalenesulfonic acids, the substances prepd. from mineral oils and isopropyl alc. sulfonated according to the method described in *Brit.* 274,611 (C. A. 22, 2268), ligninsulfonic acid, sulfonated naphthenic acids and sulfonated higher aliphatic acids. These substances may be used in the proportion of 0.1-1.0%.

Paint remover. S. HYNES. *Australia* 10,894, Dec. 14, 1927. A compn. for re-

moving paint consists of a mixt. of a soln. of wyandotte yellow hoop alkali in water with quicklime and casein.

Printing ink. KARL STEPHAN (to Chemische Fabrik auf Actien vorm. E. Schering). U. S. 1,689,868, Oct. 30. A form of MnO_2 is used, 100 cc. of which, when loosely heaped, do not weigh more than 100 g. This MnO_2 may be prepd. by pptg. a Mn compd. with Na_2CO_3 and adding Cl, and the ink may also contain a blue dye sol. in fat and varnish.

Compositions for removing paint, varnish, etc. J. G. DAVIDSON (to Carbide & Carbon Chemicals Corp.). Brit. 285,887, Feb. 26, 1927. Compds. such as di- and tri-ethylene glycols and their monoethyl ethers and the monobutyl ether of diethylene glycol are used as solvents. Brit. 285,888 refers to the use of the esters of glycol or polyglycol ethers, the acetates of the ethyl ethers of di- and tri-ethylene glycols and of ethylene-propylene glycol and similar compds. More volatile solvents may be added also.

Insulating varnish. THE ASAHI GLASS CO., LTD. Fr. 638,197, July 25, 1927. An elec. insulating varnish is made by heating glycerol and a S or Se compd. with a mixt. of resin and oil of China wood in the presence of a catalyst such as Al.

Varnish or enamel for "wrinkling finishes." FRANK B. ROOT (to Flood & Conklin). U. S. 1,689,892, Oct. 30. China wood oil 7-17 gals. is mixed with a "wrinkle finish resin" 100 lbs., using oil at least most of which has been preoxidized by blowing, and with a drier and thinner.

Composition for softening lacquered or similar surfaces. FREDERICK J. PILGRIM. U. S. 1,687,787, Oct. 16. Water 15, kerosene 30, soap 3, oil of mirbane 1, dye 1 and tripoli 50%.

Floor covering material. CHARLES O. KARPF. U. S. 1,688,239, Oct. 16. A waterproof flexible felt base is given a sealing coat of paint which is smooth and flat and on this there is applied a decorative design in ink from an etched plate having a wide-mesh screen, and before the ink is dry the flexible body is reversely bent so as to blend out the effects of the screen; a transparent wear-resistant surface coating is then applied.

Artificial resins. BAKELITE CORP. Fr. 638,084, July 21, 1927. Phthalic anhydride is caused to react on a polyhydric alc. at a temp. below 175° . The product is poured into molds and the heating continued at $90-125^\circ$ till hardening takes place. A brilliant hard resin without inherent color is obtained.

Artificial resin. BAKELITE CORP. Fr. 638,121, July 22, 1927. A resin suitable for varnishes, enamels, etc., is made by heating 100 parts of glycerol with 200 of phthalic anhydride till gelatinization begins, then 100-200 parts of a solvent of high b.p. such as diethyl oxalate or glycol diacetate is added and the heating is continued till gelatinization begins again, and then a medium b.p. solvent such as Et lactate, diethyl carbonate, or the Et ether of ethyleneglycol is added to give the desired consistency.

Artificial resins. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 638,275, June 24, 1927. Artificial resins particularly for varnishes such as phenol and glycerol resins are made sol. in org. solvents by dispersing them in esters of the aliphatic series such as a glyceride of a polybasic acid.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Total fat determination in sulfonated oils. K. RIETZ. Wiss. Zentr. Oct. Fett Forschung, Berlin. *Chem. Umschau Fette, Oele, Wachse u. Harze* 35, 270-4 (1928).—The German Commission for Fat Analysis is standardizing the methods for the analysis of Turkish Red Oil, and is broadcasting some questions for public discussion on the methods for such sulfonated oils that can be split quant. with concd. HCl. It also discusses A. H. Grimshaw's work (*C. A.* 22, 1690) and the German "Krefeld" specifications and analytical methods for Turkish red oils.

P. ESCHER

Determination of the saturated constituents of fats by the thiocyanate number. H. P. KAUFMANN. *Z. angew. Chem.* 41, 1046-8 (1928).—The thiocyanate no. for triolein is 86.08 and for trilinolin 86.65, mean 86.36; then the satd. constituents $X = 100/86.36$ (86.36—thiocyanate no. found) or: $100 - 1.158 X$ thiocyanate no. found. For the free acids (oleic and linolic) the equation becomes $X = 100 - 1.108 X$ thiocyanate no. The following values were calcd. In the first formula the figures representing the thiocyanate no. and the % satd. glycerides are, resp.: coconut oil 8.24, 90.5; palm kernel 12.97, 85.0; babassu fat 15.17, 82.4; milk fat 21.7, 74.9; cacao butter 34.5, 60.1; mutton tallow 38.5, 55.4; beef tallow 39.4, 54.4; lard 44.21, 48.8; peanut 72.38, 16.2; sesame 75.7, 12.0; olive 76.5, 11.4; corn 77.10, 10.7; wood oil 78.0, 9.7; poppyseed 78.7, 8.9;

sunflower 79.50, 7.9; almond 81.66, 5.4. A graph is shown which eliminates calcn.

P. ESCHER

The fatty acids of olive oil. K. H. BAUER AND J. MITSOTAKIS. Univ. Leipzig. *Chem. Umschau Fette, Oele, Wachse u. Harze* 35, 275-7(1928).—Analytical data of 5 olive oils from Crete are, resp.: (1) cold-pressed oil from fresh olives, no fuller's earth used, (2) fresh olives, hot hydraulic pressing, filtered through hydrosilicate and cotton, (3) oil from stored, twice hot pressed, olives filtered as in no. 2, (4) oil from black olives, twice pressed, not filtered, (5) oil extd. from press cakes by CS_2 , so-called "sulfur oil," acid no. 2.18, 7.40, 8.21, 21.12, 81.90; sapon no. 179.7, 191.83, 191.98, 195.12, 189.60; % unsapon. 5.00, 1.03, 0.87, 0.84, 1.02; I no. 84.34, 80.21, 77.61, 81.30, 80.21; % total fatty acids 94.5, 97.9, 98.8, 98.9, 98.5; % solid fatty acids 6.07, 5.72, 5.81, 5.88, 5.99; % glycerol 9.47, 9.90, 9.70, 10.18, 5.47; n_D^{50} 1.4493, 1.4502, 1.4503, 1.4503, 1.4484. The extd. oil differs considerably from the pressed oils. Its solid fatty acids were fractionally pptd. as Li salts in 10 fractions and from the m. p. and sapon no. the presence of *lignoceric acid* was detected, and confirmed from the properties of its Ag, Cu and Ph salts.

P. ESCHER

Examination of oleins by thiocyanate. H. P. KAUFMANN. Univ. Jena. *Z. angew. Chem.* 41, 19-22(1928).—K. traces the phys. and chem. properties of oleins as required for textiles and gives analytical data obtained with com. oleins by his method of detg. linolic acid by means of thiocyanogen. The oleic acid content varied between 72.41 and 81.76%; linolic acid between 8.85 and 10.89% and the satd. acids plus unsapon. matter between 9.39 and 18.48%. Since for pure oleic acid the thiocyanate no. and the I no. are alike, viz., 89.9, it follows that the grade of oleins is the higher the nearer the value reaches 89.9.

P. ESCHER

Preparation of erucic acid from rape-seed oil. K. TAUFEL AND CL. BAUSCHINGER. Deutsche Forsch. Anstalt Lebensmittelchem. München. *Z. angew. Chem.* 41, 157-9(1928).—The methods known so far for isolating erucic acid from rapeseed oil (cf. C. A. 16, 3064; 20, 1724) are unsatisfactory, because they are either bothersome, or give a poor yield, or furnish a product not strictly pure. The authors succeeded in prepg. pure erucic acid with a good yield. The sepn. from the satd. fatty acids was based on the observation that by adding small quantities of Pb acetate to the alc. soln. of the total fatty acids obtained from the oil, the satd. acids are pptd. first. The other unsatd. fatty acids were sepd. by means of Mg acetate. Twenty-five g. of cold-pressed, unrefined German rape-seed oil (sapon. no. 176.9, I no. 100.3) are sapond. hot. The alc. is removed, CO_2 being passed through the soln., the alkali soaps are decompd. by dil HCl, and the fatty acids dissolved in Et_2O . This soln. is washed with H_2O , dried with Na_2SO_4 , and the ether distd. off, while CO_2 is passed through the soln. The fatty acids obtained (23-4 g.) are dissolved in 200 cc. 96% alc. and pptd. hot with 0.4-0.5 g. Pb acetate and 200 cc. 96% alc. After filling the flask with CO_2 , and closing the flask tightly, this mixt. is allowed to stand overnight at 10-5°. Then the soln. is sepd. from the pptd. crystals, and 0.5 N KOH added, till phenolphthalein gives a slightly red color. Warm distd. H_2O is added to give a vol. of $\text{KOH} + \text{H}_2\text{O} = 200$ cc., and 65 g. Mg acetate in 100 cc. $\text{H}_2\text{O} + 200$ cc. 96% alc. are added with stirring. After standing overnight at about 15° in a closed flask, the ppt. is filtered off and washed 3 or 4 times with 50 cc. 80% alc. Decompn. of this Mg salt gives erucic acid, which after repeated crystn. appears as white crystals, m. 33.8-34.1°, and I no. 74.9. The yield is 7-8 g. i. e., about 30% of the oil.

G. SCHWOCH

Glycerol—survey and prospects. H. STADLINGER. *Chem.-Ztg.* 52, 700-1(1928).—S. attributes the economic depression in the glycerol market to the superior phys. properties and the low cost of ethylene glycol as an anti-freezing agent and as a raw material for explosives. Fermentation glycerol may become an important rival if purity and low cost are developed.

P. ESCHER

Glycerol and its substitutes in industry. W. F. DARKE AND E. LEWIS. *Chemistry and Industry* 47, 1073-92(1928).—This general descriptive account is divided into the following sections: (1) historical; (2) manuf. (including a flowsheet); (3) addnl. methods suggested or employed in war time for its manuf.; (4) specifications; (5) applications of c. p. glycerol; (6) applications of industrial glycerol including tables and graphs of (a) viscosity of aq. glycerol solns., (b) b. p. of aq. solns., (c) f. p. of aq. solns., (d) vapor pressure of aq. solns., (e) b. p. of aq. solns. at various pressures, (f) cooling properties of aq. solns. for steels compared with water and with oil, (g) compn. of low f. p. dynamites; (7) glycerol as a constituent of adhesive compds. and inks; (8) other processes employing glycerol (photography, leather, petroleum); (9) glycerol substitutes; (10) glycerol in synthetic chemistry; (11) conclusions. A lengthy classified bibliography is included.

E. G. R. ARDAGH

Chemical studies on coconut products. II. Utilization of the coconut. N. GALVEZ, R. MORENO AND V. G. LAVA. *Philippine Agr. Expt. Sta., Los Baños. Philippine Agr.* 17, 163-8(1928); cf. *C. A.* 22, 1246.—The ashes of the pinnae and petioles contain K_2O 9.67, 18.71; Na_2O 2.77, 10.67; and P_2O_5 1.93, 7.27%, resp. Coconut oil in glass containers hydrolyzes only very slightly. Samples of pure coconut oil which contained 0.15-0.23% at the beginning increased in oleic acid content to 0.31-0.60% after standing 4 months as emulsions with 0.1-39.0% H_2O . None of the samples gave a positive test for rancidity. The ashes of coconut shells and husks contain Na_2O 5.80, 2.29; K_2O 23.5, 30.2; and P_2O_5 4.96, 5.94%, resp. A general review of the subject and 23 references are given.

A. L. MEHRING

Soaps in modern textile processing. M. DANN. *Soap* 4, No. 2, 29-31, 79(1928).—The types and characteristics of soap products for scouring, bleaching and dyeing operations are discussed.

E. SCHERUBEL

Standard methods of analysis of soap. A. E. LEIGHTON. *Australia Dept. of Defence Munitions Supply Board* May, 1926, 4 pp.—The following detns. are described: moisture, insol. matter, total fatty and resin acids, resin acids, free alkali and alc. insol., alkali carbonate, alk. silicate, both in the absence and presence of mineral matter insol. in H_2O .

E. SCHERUBEL

Cold cream soaps. W. A. POUCHER. *Am. Perfumer* 23, 464(1928).—A suitable base for these soaps is white tallow, coconut and bleached palm kernel oil. No free alkali is left in the soap and the super-fatting agent is either lanolin or soft white paraffin or a mixt. of beeswax in liquid paraffin together with spermaceti or hard paraffin. The mixt. is treated with hot $Na_2B_4O_7$ soln. which partially saponifies the beeswax and forms an emulsion.

E. SCHERUBEL

✓ **Salt content in soap base and curd soaps.** J. T. *Seifensieder-Ztg.* 55, 345-6 (1928).—Soap base and curd soaps with 30% coconut oil can hardly contain less than 0.5% $NaCl$; soaps with 10% coconut oil contain not less than 0.3% $NaCl$. P. E.

Occurrence of As in fish (S'ADOLIN) 11I. Theory of the bleaching action of bleaching earths (KOBEL) 18. Lipides and their estimation in vegetable tissues (SANDO) 11A. Chaulmoogric oils. The oil of Gorli (ANDRÉ, JOUATTE) 10. Purification of fatty materials (Fr. pat. 32,762) 22.

BERLIN, E. V. *Einheitliche Untersuchungsmethoden für die Fett-Industrie. Part I.* Stuttgart: Wissenschaftliche Verlagsgesellschaft m.b.H. 105 pp. Reviewed in *J. Assoc. Official Agr. Chem.* 11, 528(1928).

Purification of waters from wool, etc., washing. CARL VAN OVERSTRAETEN. *Fr.* 637,912, Nov. 22, 1926.—The waters from wool, etc., washing are sepd. from deposits by decantation and treated with acids, $CaCl_2$ or Al_2SO_4 , the ppts. being boiled with alkali and concd. to sep. neutral fats. The residual waters are reused after neutralization, or the soaps therein are pptd. by acid and the water is rejected.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

Report on meetings of technical advisers in the Java sugar industry, Feb. 21 to 23, 1928. ANON. *Arch. Suikerind.* 36, IV(1928); cf. *C. A.* 22, 2480.—**Joint meeting of the three sections.** *Ibid* 3-37.—A round table discussion on deterioration of cane after cutting; weighing of cane and of bagasse; detn. of the yield of individual fields by the Djombang and other methods; behavior of different varieties in factory operation; relation between ash constituents in cane juice and those in soil and irrigation water; introduction of the metric system. **Joint meeting of chemical and technical sections.** *Ibid* 37-160.—Similar discussion on crushers and shredders; hot maceration; weighing of bagasse; loss of juice in bagasse; bagasse analysis; fuel economy and control; new filter presses; returning press mud to the mills; incrustation, and cleaning of evaporators; pressure evapn.; protection of metal surfaces against attack by SO_2 ; Lafeuille crystallizers; improving the quality of white sugars by remelting low-grade sugars; self-discharging centrifugals; use of steam in centrifugals; centrifugal capacity; dila. of run-offs with sirup or thin juice; sugar driers; fracturing of sugar crystals. **Meeting of chemical section.** *Ibid* 161-82.—Discussion on quantity of lime used in defecation; hot liming; use of centrifugals to remove suspended matter in juices, sirups,

and molasses; use of Hyflo-Supercel in filtering sirups and molasses; quality of massacuites and molasses where Lafeuille crystallizers are used; purity of final molasses; factory control. Meeting of agricultural section. *Ibid* 183-285.—Discussion on distance between cane plants; cultivation and time of planting; ripening and optimum time for cutting; production of seed cane (bibit); pokkahboeng and its effect; optimum quantity of $(\text{NH}_4)_2\text{SO}_4$; use of lime as a soil ameliorant; phosphate fertilization; reservoirs for irrigation water. Meeting of technical section. *Ibid* 287-318.—Discussion on boilers; furnaces; air preheaters; economizers; elec. mill drive; electrification of sugar factories; turbines; condensers; miscellaneous. Index. *Ibid* 319-25.

P. R. PEKELHARING

Report of the Technical Committee of the Chemists' Society (of Mauritius) on the combined production of white sugar, and of raw sugar, 99° polarization. ANON. *Rev. agr. Maurice* 5, 194-205(1928).—The sulfitation process is recommended; for the production of raw sugar the juice should be sulfured to an acidity of 0.6 g. SO_2 per l., and limed to the highest pH compatible with the defecator capacity. For the manuf. of white sugar the usual methods are to be employed. The 3-massecuites system is to be used, and 6 different boiling schemes for such a system are appended to the article. The 1st massecuite is to yield white sugar, the other two sugar of 98 to 99° polarization. All app. used for the 2nd and 3rd massecuite must be well washed and steamed before being used for 1st massecuite. Sugar conveyors must also be cleaned before being used for white sugar. It may not be absolutely necessary to use granulators for drying the sugars; superheated steam may be used for drying the raw sugars in the centrifugals. A max. deterioration factor of 0.333 is recommended, to prevent deterioration of the finished sugars. The official English methods are to be used for the analysis of the sugars.

F. W. ZERBAN

Decrease in operating costs in sugar factories by the use of the Kiesselbach storage-feeder. CONRAD. *Centr. Zuckerind.* 35, 805-8(1927).—The Kiesselbach app. is a large insulated pressure vessel connected to a boiler. A circulating pump continuously withdraws water from the boiler, sends it to this storage-feeder, and back to the boiler again. Thus, there is provided a reserve of water, many times the wt. of the water in the boiler proper, but at boiler temp. and pressure. During periods of low load heat is stored; during periods of sudden demand this stored water gives up steam by flash. The result is the same as that with a steam accumulator, and the savings are due to more even loads on the boiler with consequent more regular firing. W. L. B.

Which kind of current for electrification of sugar mills? Q. A. D. EMMEN. *Arch. Suikerind.* 36, II, 648-52(1928). The opinion is generally held that a. c. should be used in sugar factories, except for driving the mills. The only advantage of d. c. for the latter purpose is that it is easier to regulate the speed of the sep. mill units, and that it causes less loss than a. c. As in the near future only cane of the variety POJ 2878 will be ground, such regulation of the mill speed will not be required, and a. c. will be preferable for the mills also.

P. R. PEKELHARING

New methods of operation in mixed factories. A. KÜHNEL. *Z. Zuckerind. czechoslov. Rep.* 51, 551-4, 563-6, 612 4, 694-6(1927). Over 1800 expts. were carried out by heating 400 cc. of various sugar solns. with 0.1% active C, for 5 min. at 85°. The results are given in 12 graphs. Both carboraffin and polycarbon do 80-90% of their work in the 1st minute. The amt. of decolorization is relatively greater for smaller quantities of C. The rate of decolorization is faster with larger amts. Removal of some Ca from juice by adding H_3PO_4 improved the action of the carbons. Without this action the C became coated with colloids and lost its activity, and the $\text{Ca}_3(\text{PO}_4)_2$ ppt. adsorbed some of the colloids. An addn. of 0.7% gum arabic lowered the color removal from 67 to 46%. Pepsin had a similar effect, and so did an increase in alk., though the effect of the latter was most marked between 0.016 and 0.021. Addn. of CaCl_2 up to 0.7% considerably increased the activity of the C. Addn. of gum up to 0.5%, pepsin up to 0.5%, and alkali up to 0.015%, all lowered the decolorization from 67% to about 50%. Gum + pepsin had about the same effect. Gum + pepsin + alkali lowered it to 24%. Microscopic examn. showed pulp cells in the juice which not only added gums and proteins but color also. Removing these in a super-centrifuge of 30,000 r. p. m. gave a juice which after carbonation had only half the usual color. This has not yet been adopted on the factory scale. W. L. BADGER

The use of superheated steam in the sugar factory. JOSEF JASKÓLSKI. *Centr. Zuckerind.* 35, 559-62(1927).—The mill at Vyskov (Czechoslovakia) has available steam at 225 lb. gage and 190 to 360° F. superheat, steam at 100 lb. gage and 125° F. superheat, and satd. exhaust at 19 lb. gage. The av. steam consumption of the triple effect under pressure is 31% steam on the wt. of the beets. This is made up of

20% turbine exhaust with some superheat, 8% pump exhaust (satd.), and 3% high-pressure steam from the boilers. These are mixed and desuperheated with water sprays just before the evaporator throttle valve. Three expts. were run as follows: (1) no water sprays and max. superheat at the evaporators, (2) partial spraying with moderate superheat, and (3) no superheat at the evaporators. The steam to the 1st effect was at 19–20 lb. gage in all cases. (Satn. temp. 125°.) Temp. of steam as admitted to 1st effect: (1) 151°, (2) 120°, (3) 129°; temp. in steam space of 1st effect, (1) 122.1°, (2) 122.2°, (3) 122.3°; increase in color of juice, (1) 12%, (2) 10%, (3) none; coal per 100 kg. beets, (1) 4.79 kg., (2) 4.69 kg., (3) 4.63 kg. The figures on coal consumption are not considered conclusive, as the possible errors are greater than the differences observed. Use of superheat in the evaporators resulted in considerable difficulty in collecting and handling condensate. Since the use of superheated steam causes complications, is harmful to the color of the juice, and does not save coal, it is considered undesirable.

W. L. BADGER

Experiences with purification of sugar factory pulp-press water by fermentation. OTTO UNGNADE. *Centr. Zuckerind.* 35, 1097–8(1927).—The press water was collected separately and allowed to undergo lactic acid fermentation. This removed all sugar, and apparently modified the rest of the org. matter somewhat. It was then limed, and this pptd. not only Ca lactate, but also most of the albuminous substances. The result was a clear effluent, which was mixed with condenser and beet-flume water and sent to settling basins. There were enough bacteria in the effluent to effect considerable further purification in the settling basins. Previously this mill had to return the press-water to the battery. Eliminating this necessity made possible a lower draft in the battery, which relieved all subsequent stations. No effect was noticed on sugar losses. There was a slight loss of dry substance in the pulp. Suspended matter was lowered from 8560 to 2300 mg. per l., total N from 112.0 to 28.0, org. N from 88.2 to 15.4 and permanganate consumption from 19,435 to 1140. Lactic acid in effluent averaged 864 mg. per l.

W. L. BADGER

Determination of the composition of sugars. P. HONIG. *Arch. Suikerind.* 36, II, 639–47(1928).—During the crop of 1928 the sugars from a large no. of Java mills were analyzed. Monthly or fortnightly samples were sent to the expt. station and tested for polarization, H_2O , reducing sugars, ash, p_H , grain size and color. A better insight into the quality of the different grades, and their chem. and phys. compn. is thus obtained. The analytical methods used are described in detail. P. R. PEKELHARING

Determining suspended solids. S. S. PECK. *Facts About Sugar* 23, 1017(1928).—For routine control in Hawaii P. proposes to replace the present laborious method of direct estn. by an indirect one based on the relationship between the suspended matter in the juice and the dry non-sucrose in the press cake, in which the working factor representing this relationship would be redetd. periodically. M. J. P.

The conductometric determination of ash in sugar house products. K. ŠANDERA. Research Inst. of the Czechoslov. Sugar Ind. *Z. Zuckerind. czechoslov. Rep.* 51, 603–12(1927); *Listy Cukrovar* 45, 459 ff(1926–7); cf. *C. A.* 21, 3480, 3481.—The app. previously described has been made more compact. A case about the size of a microscope case carries the lamps and resistances in a back compartment, and the cell is attached to the door. A thermometer dips into the soln., and the correcting resistance is controlled by a dial graduated directly in degrees. The elec. method does not show insol. ash; but this is an advantage since insol. ash should not be considered in calcg. rendement. The sp. cond. of the various salts which might be present varies widely, but the variations in compn. of ash in sugar house products will not ordinarily cause an error of over 1% of the total (i. e., ± 0.01 – 0.02% ash on average materials). W. L. B.

New instrument for determining the specific gravity of refined sugar. V. YANOVSKII. Lab of Leningrad Inst. of Technology. *Bull. Sakharotrest (Bull. of the Sugar Trust)* No. 1, 53 60(1928).—The sp. gr. of a weighed piece of refined sugar can be detd. by displacing a certain vol. of kerosene in a volumometer designed by Y. The temp. has no effect on the instrument. The testing is rapid and accurate, with an abs. error of not over 0.5%. The method of using the app. and calcg. the result is given and a drawing of the instrument is shown. V. E. BAIKOW

Decline in the quality of sugars in connection with circulation of run-offs. J. E. ROEM. *Arch. Suikerind.* 36, II, 652–6(1928).—The quality of plantation white sugar in Java is inferior to that of whites produced in Europe. During the course of the campaign the Java white sugar gradually goes off in color. It is pointed out that the circulation of run-offs, causing higher viscosity and color, is partly responsible for this decline. Expts. at Tandjong Tiro during the 1927 crop have shown that when at the double purging C sugar is mixed with A and B sugars, the wash is lower in purity and

higher in color and viscosity than when the A and B sugars are double purged separately. When the double purged A, B and C sugars are worked up together much more water must be used to get the right color. Expts. with the de Laval centrifuge have shown that the wash has a bad effect on the quality of the sugar. When the C sugar is double purged separately, the quantity of the wash is smaller, and the quality of the product is better.

P. R. PEKELHARING

Inversion losses in gur sugar manufacture in North Behar. JOHN H. HALDANE. *Intern. Sugar J.* 30, 363-5(1928).—The compn. of "Gur" varies within the following limits: polarization, 65-74%; invert sugar, 8-14%; ash, 2.5-5.5%; purity, 70-78. Formerly the procedure in "Gur" refining was to melt it to approx. 50-55 Brix at a temp. of 50-60° and lime until slightly acid to litmus. The major portion of the "Gur" sirup is stored over a period of 12-16 hrs. It was noticed that the p_H would be lowered from 5.4 to 4.4 accompanied by a decrease in purity of 1.2-2.5. The abnormal losses of sucrose reported by "Gur" refiners may be attributed to (1) the method of liming the melt to "slight acidity towards litmus" and the subsequent development of acidity when the sirup is stored for any length of time, (2) the concn. of acid sirups to massecuites, when the light and heavy acid molasses are reboiled to produce a low-grade massecuite. By correcting these faulty practices the unknown loss of sugar in "Gur" refining has been reduced to 2.2%.

W. L. OWEN

Methods of sugar boiling. HERBERT WALKER. *Intern. Sugar J.* 30, 372-6(1928).—The importance of raw sugar manufacturers turning out a product of "good refining value" is universally recognized. The "filtration rate" of sugars is in inverse ratio to the proportion of finely divided insol. impurities in the sugar, and this will depend upon the method of sugar boiling used. Three methods of sugar boiling are described, two being of very general practice, viz., the two massecuites system and the Pioneer; and the third a combination system, recommended by W. The advantages and disadvantages of the 3 systems are discussed.

W. L. OWEN

Cane sugar industry of Rio de Janeiro. RICARDO AZZI. *Facts About Sugar* 23, 974-5(1928).—The soil and climate conditions are very promising. The only cane disease of importance is mosaic, to which all the varieties now generally grown in this district are susceptible. The few insect pests do not seem to do much damage. The methods of prepng the land, the planting, cultivation and harvesting and the basis of cane buying are briefly described. The cane is not bought by analysis and there is no chem. control of the manuf. A table is given, showing the names, ownership and production (in unstated units) for the 3 years of 1925-6-7.

M. J. PROFFITT

Cane root studies in tile-drained soil. W. P. ALEXANDER. *Facts About Sugar* 23, 1050-1(1928).—Estn. (by excavation and hand sepn) of the root development of a crop of H-109 cane grown in a heavy adobe soil with and without tile drainage confirmed the general observation that poor drainage prevents normal root development. The proportion of root growth occurring in the strata 24 to 40 in. below the surface in the drained area was comparable with that often obtained in sandy loam. Large root development was correlated with better yield. Drainage not only allows better aeration of the soil, but it also reduces the concn. of sol. salts in the soil at all levels from the kuakua to the fifth 8-in. stratum, as shown by a table included.

M. J. PROFFITT

The beet campaign of 1926-7 in Moravia. JAROSLAV FIŠER. *Z. Zuckerind. czechoslov. Rep.* 51, 689-96(1927).—The av. for Moravia, Silesia and Slovakia was: wt. of leaves, 348 g. per beet; wt. of root, 485 g.; sugar content, 17.89%. The av. for 24 mills in Moravia (56% of the total) was: kg. chips per hl. in cells, 55.2; cells per 24 hrs., 232; draft, 115; pressed pulp, 63%; lime consumption, 4.7%; raw sugar yield, 17.2%; molasses yield, 1.76%; coal consumption, 6.79% for mills with vacuum evaporators, 5.23%.

W. L. BADGER

2nd fillmass, 93.3%; in molasses, 82.1%. Purities: diffusion juice, 90.1; thin juice, 94.3; thick juice, 94.8; 1st fillmass, 92.2; high green, 76.8; 2nd fillmass, 81.0; molasses, 64.6. In general, all stations operated normally. Filtration of thin juice through a layer of partly exhausted active C accomplished some decolorizations, but by complete removal of suspended matter greatly improved the operation, and decreased the C consumption, in later decolorizing operations. Losses were: known, 0.45%; unknown, 0.55%.

W. L. BADGER

Automatic control of the carbonation process in beet-sugar manufacture. R. T. BALCH AND J. C. KEANE. *Ind. Eng. Chem.* 20, 1148-51(1928).—Equipment similar to that previously described as used for automatic control of cane juice defecation (*C. A.* 22, 1698) was tried in a beet house. The app. and installation are described

and illustrated, and a facsimile of p_H records is shown. "Automatic control of the 2nd carbonation has been shown to be practicable. If SO_2 could be delivered to the sulfitation station under as const. conditions as the CO_2 is delivered to the carbonation station, an automatic control employing similar equipment would be as successful. The control functions on electrometric principles whereby the e. m. f. produced between the W and HgCl electrodes immersed in the juice causes the elec. motor that is connected to the gas valve to operate indirectly through a system of relays. The supervision required, principally for changing and caring for the electrodes, is believed to be more than compensated by the advantages of the control." F. W. ZERBAN

Drying of sugar beet and extracting the sugar from it in a diffusion battery. N. L. KARAVAEV AND A. P. PALKIN. Lab. of Central Asia Univ. *Bull. Sakharotrest (Bull. of the Sugar Trust)* No. 5, 40-4(1928).—Sugar beets sliced and dried to 8-10% H_2O in the sun can be stored for an indefinite time without spoiling or increase of invert sugar. The exptl. run was made on 3 samples (4 yrs., 1 yr., and 5 months old) in a lab. diffusion battery. The results indicate that % sugar in diffusion juice is about double that from fresh beets if the time of diffusion is increased 50%. The purity of diffusion and limed juice is about the same. CaO used is much less if calcd. on sugar extd.

V. E. BAIKOW

The Oxford beet dehydration process. ANON. *Intern. Sugar J.* 30, 426-7(1928); cf. *C. A.* 21, 202, 1368, 2198.—The Oxford process has been in operation at the Eynsham exptl. factory for over a month, and the results have shown the following advantages: (1) a saving of 8 £ per ton of sugar made; (2) the production of an innocuous effluent; (3) the production of a superior pulp for cattle food due to its albuminoid content which usually passes into the juice. A still further advantage will result from the drying of the slices at local stations, with a saving of transport charges. One of these drying stations is now under construction at Taunton.

W. L. OWEN

Determination of solubility of sucrose in beet-house sirup. R. J. BROWN, J. E. SHARP AND H. W. DAHLBERG. *Ind. Eng. Chem.* 20, 1130-2(1928).—Soly. data of this nature are known only for European conditions. In the present study American products have been examd. Solns. of known impurity-water ratio were prepd. from a low purity molasses. Sucrose was added to these solns., the mixts. were agitated in a thermostat, and the sucrose concn. at equil. was detd. at 40°, 50°, 60°, 70° and 80°, approaching equil. from both undersatn. and supersatn. The excess sucrose was removed by filtration through metal cloth, the dry substance detd. by a method previously described (*C. A.* 22, 4267) and the sucrose found by difference. The results are shown in a table and 3 graphs. The values read from the graphs are accurate within 0.2% except at 80° where the error is slightly greater. The investigation will be continued with other low grade products as a basis.

F. W. ZERBAN

Farm or field roots. FRANK T. SHUTT. Dept. Agr., Canada. *Rept. Dominion Chemist, Year Ending March 31, 1927*, pp. 31-4(1928).—Expts. were carried out with 15 varieties of mangels to det. the relation between type, based on the length-width ratio of the root, and nutritive value as measured by dry matter and sugar content. The results, thus far obtained, indicate that in general the "long" and "half-long" types contain the highest percentages of sugar in juice and of dry matter. Limed soils produced much higher yields of mangels than unlimed soils but mangels from unlimed soils contained higher percentages of dry matter and sugar in juice. The sugar in juice content of 5 varieties of carrots varied from 1.04% in the Champion variety to 2.67% in the Improved Danver's Half-Long

K. D. JACOB

The diseases of the beet. FR. RAMBOUSEK. Research Institute of the Czechoslovakian Sugar Industry. *Z. Zuckerind. czechoslov. Rep.* 51, 559-63(1927).—A systematic table based on visible symptoms.

W. L. BADGER

Boiling of massecuites with the aid of the electric current by the method of Gränz-dörffer. YU. ZHVIRBYANASKII. *Bull. Sakharotrest (Bull. of the Sugar Trust)* No. 3, 56-9; No. 4, 20-34(1928).—In the method of Gränz-dörffer electrodes are placed in the vacuum pan, and a cs. of varying intensity are passed through the massecuite during boiling. A definite quantity of sugar powder is introduced to start crystn., and thick juice is drawn in continuously. The process is being used in a German factory, but it offers no noticeable advantage in the time of boiling, shape of crystals, or steam economy. Comparative tables, pictures of crystals, and various diagrams and drawings are shown.

V. E. BAIKOW

Control of massecuite boiling. ROJ. *Bull. Sakharotrest (Bull. of the Sugar Trust)* No. 2, 38-9(1928).—The "Brasmoscope" of R. is composed of a U tube attached to a board. The tube is filled with Hg. One end of the tube is connected with the vacuum pan; the other one is open. On the surface of the Hg in the open end floats a small

bottle (filled with Hg) which is connected, by a silk thread running over a pulley, with an eccentric and a scale which indicates % H₂O. Depending on the pressure in the vacuum pan, the scale indicates to the sugar boiler the % H₂O in the massecuite. A very simple table, by Dokhlenko, is attached to the app., by which the sugar boiler can easily calc. when and how much thick juice must be added to the massecuite. This instrument permits const. control of the massecuite. A full description and a drawing of the instrument are given. V. E. BAIKOW

The importance of proper juice screening. J. W. STEENBLIK. *Facts About Sugar* 23, 1022-3(1928).—The use of elec. vibrating screens in place of the old type of screens in 5 Cuban mills, 2 of which used the Petreé-Dorr process and 3 of which used filter presses, has resulted in increased efficiency and improved product. M. J. P.

Filter for juice of first and second carbonatation with mechanical cleaning. YU. D. LYUBCHENKO. *Bull. Sakharotrest (Bull. of the Sugar Trust)* No. 3, 33-6(1928).—The new filter consists of a rectangular tank with a horizontal plate at the top. A no. of vertical plates are attached to the top plate and are covered with filter cloths. The juice enters at the bottom and is pumped out through a pipe at the top, forming between the plates filter cakes which are washed and blown down by compressed air or steam. The cloths are scraped by a set of scrapers of special construction. The sludge is mixed by a propeller at the bottom of the filter and finally sucked out. The advantages of the filter are small space occupied by it (2.25 m.), reduced labor, and continuous work. The filter cloths can be changed by taking out the entire block of plates at one time and replacing with new ones. V. E. BAIKOW

Rationalization of mechanical filters. YU. D. LYUBCHENKO. *Bull. Sakharotrest (Bull. of the Sugar Trust)* No. 1, 37-8(1928).—Greater economy of labor and filter cloths, also perfect filtration of thick juice and sirups, can be obtained in a filter designed by L. The filter, in which are suspended filter plates covered by a small-mesh screen, is filled with a mixt. of cellulose and water. The cellulose is deposited on the screen and becomes a perfect filtering material. After filtration of the sirup the cellulose can be washed out by reversing the current of water. V. E. BAIKOW

Memorandum on burlap as a supplement to filter press cloths. D. C. BOLIN. *Intern. Sugar J.* 30, 486(1928).—The occasion often arises when it is necessary to increase the capacity of the filter press station. This can be done by increasing the existing equipment or by increasing the efficiency of the equipment. In British Guiana, because of the nature of the soil, the filtration of scums and settlings and clarified juice is comparatively slow. A large filtering area is necessary to avoid discharging soft cake. Although treating the scums with phosphoric acid and "Filter Cel" aided filtration, this proved an added expense without commensurate benefits. Burlap was tried as a covering for the filter cloths and very striking benefits were obtained. The material used was D. W. Twilled Burlap sacking; an increased rate of filtration was immediately noticeable. W. L. OWEN

Hydrogen-ion control of boiler feed waters. ANON. *Intern. Sugar J.* 30, 475-6(1928).—In sugar factories condensed water from the evaporators may contain varying amts. of sugar, which is decompd. in the boilers with the formation of org. acids, which injure the boiler plate. This can be avoided by maintaining the alky. of the water at the optimum p_H which is between 9.5 and 10.0. Recently there has been introduced the Rees colorimeter for the control of the reaction of condenser and boiler feed waters. The instrument measures out a small quantity of indicator (phenolphthalein is recommended) and mixes it with another large quantity of liquid, *i. e.*, the water under examn. After transferring the mixt. to an observation tube, it is compared with a sliding color wedge. The p_H of the boiler water being known one reads from a table prepd. for the purpose the necessary vol. of NaOH soln. of suitable concn. to be added. Feed or boiler water must never become more acid than p_H 4.5 since at this value H begins to be evolved from Fe at ordinary concns. of O. W. L. OWEN

An enquiry into methods for the purification and disposal of waste waters. PARK ROSS AND L. F. DE FROBERVILLE. *Intern. Sugar J.* 30, 376-82(1928); cf. *C. A.* 22, 2677.—The nuisance from waste waters in South Africa having attained serious proportions it was decided to investigate European methods for the disposal of such effluents. The standards for the effluents discharged in fishing rivers are: (1) they should not contain more than 3 pts. per 100,000 suspended matter; (2) they should be non-putrescible on incubation for 5 days at 18°; (3) they should not absorb more than 1.5 pts. by wt. per 100,000 of dissolved or atm. O in 5 days. In Natal the waste waters are principally from 2 sources: (1) molasses distilleries and (2) sugar factories. The waste waters from the former are from 2 sources, *viz.*, the residues from the stills, and the bottoms from the fermenters. The stills are supplied with decanted wort from the fer-

menters, and therefore contain a min. of suspended matter, but some fermentable sugars which have to be eliminated. By pptn. of the wort with lime before concn., the wort remaining in the bottom of the tubs is much more solid and easier to handle. The possible methods of disposing of these wastes are (1) application to the land; (2) evapn.; (3) biological purification. Of the 3 methods the last seems best adapted to South African conditions. In this method all of the pot ale (450,000 gals.) is collected in one tank (a), and the other polluting waters in another (b). A mixt. of 1 part of (a) and 7 of (b) is made and to each 300 gal. 1 lb. of lime is added during the mixing. After settling 24 hrs. the supernatant liquor is drawn off and sent to the biological filter. After leaving this filter with its ammoniacal and albuminoid N reduced to a safe minimum, the effluent is sent over sand filters to remove the suspended matter. Purified effluent was entirely uninjurious to fish. Of the various methods considered for the treatment of cane factory waste waters, the chem. pptn. method, and the recovery and reuse of the water in the factory is the best for the conditions in South Africa.

W. L. OWEN

How must saturation with sulfur dioxide be carried out? LUDWIG KAYSER. *Centr. Zuckerind.* 35, 722-5(1927).—The p_H of the entering juice is fixed at some value a by conditions of carbonation and filtration, and the final p_H desired is fixed at e by conditions in evapn. and boiling. These are both assumed to be on the alk. side. Sulfuring may be carried out (I) by simply sulfuring from a to e ; (II-1) by adding CaO to give the juice a p_H of Z , higher than a , and then sulfuring from Z to e ; (II-2) by sulfuring to e , adding CaO to give a p_H less than a , sulfuring to e , and repeating till the desired amt. of CaO has been used; (II-3) sulfuring with continuous addn. of CaO so that the whole process takes place practically at e ; (III-1) sulfuring from a to a p_H of y on the acid side, and then adding CaO to come back to e ; (III-2) sulfuring to y , adding CaO to give a p_H greater than y but less than e , sulfuring to y , repeating till the desired amt. of CaO has been used, ending at e ; and (III-3) sulfuring at y with continuous CaO addn., ending at e . Expts. are cited showing that up to a p_H of 5.5 there is no inversion in pure sugar solns.; and since all factory juices contain buffer substances, this limit is amply safe in practice. A no. of expts. were made at different concns. and different purities by methods II and III, and the following conclusions reached: The decolorizing effect is better, the lower the av. p_H during sulfuring. This is true both for bleaching the coloring substances, and for the adsorption of color on the $CaSO_3$ ppt. formed. A p_H of 5.5 is safe up to 85°. If juices of varying d. and purity are sulfured without addns. of CaO, the decolorizing effect is better with the thinner and less viscous juices. When there are small addns. of CaO, the results are better as the d. or purity of the juice is higher, but this effect is far overshadowed by the effect of changes in the amt. of CaO used. If 0.05% of CaO is added in sulfuring thick juice, twice as much color is removed as when sulfuring without CaO.

W. L. BADGER

Is it advantageous or not to cover the diffusion battery with insulation? B. HEINEMANN AND P. HOPPE. *Centr. Zuckerind.* 35, 1044-6(1927).—Four parallel tests were made on 2 batteries of 8 cells each. In one battery the cells were insulated and in the other they were bare. The 2 batteries were run under as nearly identical conditions as possible. The wt. of steam condensed was exactly the same for the covered battery as for the bare one, in each test.

W. L. BADGER

Fitting shells to roller shafts. R. B. KAY. *Facts About Sugar* 23, 1023-4(1928).—The replies submitted to a questionnaire sent to various equipment manufacturers and sugar factories indicates that the trend of modern practice is toward a simple shrink fit.

M. J. PROFFITT

Tube plates for multi-pass heaters. P. H. PARR. *Intern. Sugar J.* 30, 473-5 (1928).—Under modern conditions the multi-pass heater or heat exchanger is becoming of great importance, not only for juice heaters in sugar factories but also in chem. engineering. The "setting out" of the tube plates for these heaters often gives considerable amt. of trouble, much of which can be avoided by the following method. First a rough est. is made of the diam. of the heater, and then a rough drawing is made showing this divided up into a no. of equal areas corresponding to the no. of passes (traverse flows, etc.) as required. The circles may be divided into the required no. of sections by radial lines, but circular sectors are not of good shape for holding the tubes, and a rectangular system is to be preferred.

W. L. OWEN

Comparative results obtained in viscosity tests on starches used by North Carolina mills. A. H. GRIMSHAW. N. C. State College. *Textile World* 74, 1963-5(1928).—See C. A. 22, 4256.—A further report of tests on the 63 starches submitted by N. C. mills. A description of tests used by several starch firms for detg. viscosity is included.

RUBY K. WORNER

Potato starch. I. K. HESS, HERMANN FRIESE AND FRANKLIN 'ARTELL' SMITH. *Ber.* 61B, 1975-82(1928).—*I. Acetylation.* Air-dried potato starch (I) contg. 18% water was pretreated by shaking for 24 hrs. with pyridine and then acetylated at 50-70° on the addn. of Ac_2O . After 4 days a triacetate was formed which was completely insol. in all customary solvents. The yield is almost theoretical. Alc. NaOH regenerated (I) unchanged. The triacetate of amylopectin is insol. but amylose triacetate is readily sol. in Me_2CO , CHCl_3 , etc. Expts. were then planned to show whether amylose pre-exists in starch or is formed by the process of sepn. *II. Action of warm water on potato starch.* Agitating (I) with water at 50-55° sepd. it into a sol. fraction (II) which composed 69% of (I) and an insol. residue (III). At 80° 31.8% of (III) dissolved to give fraction (IV). The material insol. at 80° (V) is amylopectin and contained 0.209% P_2O_5 . (II) and (IV) are amyloses. Microscopic examn. revealed that the outer shell of the starch granule was made up of (II) and (IV) exclusively and that the nucleus of the granule was composed of (V). The water-sol. fractions (II) and (IV) were shown to be heterogeneous by fractional pptn. The more sol. fractions contained up to 11.8% of reducing sugar and the product of acetylation gave higher acetyl values than did the acetate of (I). Fraction (II), however, did not reduce Fehling's soln. and complete acetylation gave an acetate with the same acetyl content as the acetate of (I). Conclusion: Although water at 80° partially hydrolyzes potato starch, at least a part of the amylose preëxisted in the original starch. J. G. McNALLY

Soil surveys (EARLE) 15. Field problems on an unirrigated plantation (SPALDING) 15. Apparatus for drying or cooling starch (U. S. pat. 1,690,013) 1. Sugar crystals. AUGUST GRANTZDÖRFFER. Fr. 638,328, July 27, 1927. In concg. sugar solns. to obtain crystals an a. c. is passed through the soln., whereby a more rapid formation of uniform crystals is obtained and org. material is prevented from entering the crystals. Fr. 638,327 describes electrodes used for sepg. crystals, particularly from sugar solns., in which the sides facing one another are cut to a point or chisel-shaped and have perforations terminating at the points of exit of the current. The electrodes may be hollow and used for leading in superheated steam.

Sugar and paper pulp from cane. EUGENIO A. VAZQUEZ (to Vazcane Process, Inc.). U. S. 1,688,904, Oct. 23. The material is sepd. into fibers and these are leached and sepd. from the liquid and sugar is recovered from the latter. U. S. 1,688,905 relates to app. for use in processes of this character.

Cyclic processes of using barium compounds in sugar production. HENRY W. DAHLBERG. U. S. 1,688,071, Oct. 16. Insol. Ba material such as BaCO_3 is converted into a sol. Ba compd. by heating with alumina to form a Ba aluminate compd. contg. water-sol. barytic material, this sol. material is used to treat molasses and form a Ba saccharate, Ba is sepd. from the latter by CO_2 and the insol. Ba compd. thus obtained is used for the production of more Ba aluminate material.

Diffusion battery and press-worm system for extracting sugar on the counter-current principle. A. RAK. Brit. 286,125, May 7, 1927. An app. is described.

Preparing cane molasses for use in manufacture of yeast by the aeration process. FRED RANSOHOFF. U. S. 1,688,831, Oct. 23. The molasses is treated with sufficient NH_3 to render it alk., and NH_4 phosphate is added and undissolved substances are sepd.

Clarifying cane molasses for the growing of yeast. CHARLES HOFFMAN, CHARLES N. FREY AND FRANK M. HILDEBRANDT (to The Fleischmann Co.). U. S. 1,687,561, Oct. 16. A dil. soln. of the molasses is treated with a quantity of Na silicate sufficient to render the resulting mixt. alk. within the limits represented by a pH value of from 7.7 to 12, and the mass is then heated and filtered while hot.

Starch. G. M. MOFFETT (to Corn Products Refining Co.). Brit. 286,289, March 3, 1927. See U. S. 1,655,395 (C. A. 22, 1054).

Starch compositions. O. MEYER. Brit. 286,377, Dec. 6, 1926. Readily pulverizable starch adapted to swell in cold water is prepd. by mixing starch (e. g., potato starch) with a small proportion of cyclohexanone or methylcyclohexanone (suitably about 3% the wt. of the starch), adding caustic alkali soln. and adding an acid such as oxalic acid to obtain a neutral product before drying. When mixed with cold water the product makes a good adhesive.

Apparatus for manufacture of dextrin from starch, etc. WM. A. DARRAH. U. S. 1,689,379, Oct. 30.

29—LEATHER AND GLUE

ALLEN ROGERS

Tanning materials of the British Empire. ANON. *Bull. Imp. Inst.* 26, 311-22 (1928); cf. *C. A.* 22, 2289.—A review of the distribution and uses in the British Empire of the following lesser-known tanning materials, which are not at present in commerce but which appear to be worthy of consideration: *Anaphrenium argenteum* E. Mey (= *Rhus Thunbergii* Hook.), *Anogeissus latifolia* Wall, *Callitris* spp. (Australian pine barks, cypress pines, Coniferae), *Carissa spinarum* A. DC., *Colpoon compressum* Berg. (= *Osyris compressa* A. DC.), *Elephantorrhiza Burchellii* Benth., *Eucalyptus alba* Reinw., *E. calophylla* R. Br. (red gum), *E. diversicolor* F. Muell (karri), *E. gomphocephala* DC., *Phyllanthus emblica* Linn., *Pinus halepensis* Mill (Aleppo pine), *P. longifolia* Roxb., *P. khasya* Royle (Burma hill pine), *Shorea robusta* Gaertn., *Terminalia arjuna* Bedd.

A. PAPINEAU-COUTURE

Measuring the color of tanning materials. A. DE LA BRUERE. *Halle aux cuirs* 1928, 265-71; cf. *C. A.* 22, 4866.—The detn. of the color of tanning exts. by the Lovibond tintometer is inaccurate. Data are presented showing (1) that different operators get different results with the same soln. under the same lighting conditions; (2) that the same operator gets different results with the same soln. under different lighting conditions; and (3) that the practice of detg. color in a soln. of analytical strength and calcg. results to a soln. contg. 0.5% tannin is not justified. The portions of the spectrum transmitted by the yellow and red glasses of the tintometer overlap widely. The spectrophotometer is too costly and its manipulation too delicate for use in control work. The detn. of color by the Toussaint photoelec. colorimeter is advocated. This instrument consists of a photoelec. cell, galvanometer, and 7 color filters transmitting nearly monochromatic light. White light from an Fe arc is rendered monochromatic by passing through 1 filter. The light passes through the soln. and impinges on the photo-sensitive element. The amt. of light of any particular color that is transmitted is measured by the galvanometer deflection, divided by the galvanometer deflection obtained when the same light is passed through H₂O. The ratio, deflection with tannin soln.: deflection with H₂O is plotted as a function of wave length, giving a curve characteristic of the quality and intensity of the color of the soln.

H. B. MERRILL

Standard methods of analysis of dubbing. A. E. LEIGHTON. *Australia Dept. of Defence, Munitions Supply Board* May, 1926. 3 pp.—Dubbing consists of any or all of the following: cod oil, mutton tallow, mineral oil and oil of wintergreen. The mineral oil is detd. as the unsapon.; the cod and tallow are detd. from the I. no. of the dubbing by calcn. The oil of wintergreen is detd. by conversion into salicylic acid which is estd. colorimetrically.

E. SCHERUBEL

Dyes and tannin from Pistachio trees. C. D. MELL. *Textile Colorist* 50, 683-4 (1928). *Pistachio terebinthus*, the so-called Cyprus turpentine tree, is the most widely distributed species and produces most of the galls of commerce. The amt. of tannin varies from 60 to 75%.

RUBY K. WORNER

Manufacture and dyeing of artificial leather. A. J. HANLEY. *Proc. Am. Assoc. Textile Chem. Colorists* 1928, 236-43; *Am. Dyestuff Rept.* 17, 656-63.—This lecture was followed by a long discussion with many questions and answers. L. W. R.

Treating leather. CARL FREUDENBERG G.m.b.H. Fr. 638,257, July 26, 1927. In mineral tanning skins or leather, the leather while damp is impregnated with an emulsion of wax to save or replace the usual dressing.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

The constitution of rubber. HEINRICH LOEWEN. *Kautschuk* 4, 163-4(1928).—It is considered that colloid-chem. research will not in itself solve the problem of the constitution and unique properties of rubber. Fundamental research on the org. chemistry of the rubber mol. is just as necessary, for it is unlikely that rubber is the only substance whose properties depend upon chem. constitution. The great difficulty in ascertaining the chem. constitution of rubber has been the fact that most of its derivs. are also amorphous and of mol. wts. of the same order of magnitude as rubber. The ozonides are about the only derivs. which can be converted into relatively simple compds. The present paper is a preliminary report on a scheme of research, the object of which is to obtain derivs. of rubber which will throw light on the structure of the latter. As a reagent, HCl was considered preferable to Br, because rubber-HCl is more stable than rubber bromide, and because a higher halogen content (with Br) involves more complicated decomps. Assuming rubber to contain the group— $\text{CH}_2\text{CH}:\text{CMe.CH}_2$, it is shown that with HCl, several addn. reactions are possible, with formation of various known compds., depending upon whether partial or complete satn. occurs, upon the part of the mol. where partial satn. occurs, and upon the subsequent character of the cleavage. Crepe (extd. with AcMe) in CHCl_3 was first treated with 0.5 the quantity of HCl gas calcd. for complete satn., after which it was ozonized. The ozonide soln. was then warmed to 70° with water, the HCl neutralized with CaCO_3 , the CHCl_3 evapd., more water added and distd. at 125-35° to 0.5 its vol. The distillate contained probably levulinic aldehyde, while the red-yellow aq. residue contained a light yellow *semi-solid*, which was sol. in EtOH and was not a rubber-HCl. This EtOH soln., after filtration, gave a *ppt.* partially sol. in dil. NaOH, the latter soln. giving in turn *ppts.* with acids, Ba salts and Pb salts. Ext'd. with Et_2O and evapd., the red-yellow aq. soln. (*loc. cit.*) yielded a light yellow *oil*, while the residual soln. from the extn. gave on evapn. a dark *oil*. This latter oil crystd. to a mixt. of 2 substances, which were sol. in EtOH, insol. in Et_2O and gave *ppts.* with sol. Pb or Ba salts. These various compds. have not been identified, but the expts. show that volatile and crystallizable derivs. can be obtained from rubber without subjecting the latter to very energetic reactions. C. C. D.

Improvement of the properties of rubber by a technical change in its microstructure. H. POHLÉ. *Gummi-Ztg.* 42, 2687-8(1928).—A large no. of photomicrographs in natural colors shows the relation between the stress-strain curves of vulcanizates and their microstructures, the curves depending upon the particle size and the state of dispersion of the "active" fillers. The particles which play a predominant role in the quality are of microscopic dimensions, and microscopic analysis will therefore show in what way particles of different sizes influence the stress-strain curves. The influence of particle size on the stress-strain curve can, however, be detd. only when the same substance is under consideration. Under these conditions it is possible to change the shape of a stress-strain curve from convex to concave or *vice versa* by the addn. of a small proportion of particles of a different size to a filler, e. g., by the addn. of a small proportion of colloidal graphite to gas black. Sb_2S_3 , Sb_2S_5 , factice, mineral rubber and different grades of ZnO and C black can be identified by photomicrographic analysis. In the colloidal form, fillers usually show microscopically a granulation of a characteristic color, which enables the particles to be identified and their fineness estd. Thus under a magnification of 2000, C black shows a fine red-brown granulation, while lamp black and "Thermax" appear different enough to be distinguishable both with respect to their identify and their fineness. A uniform appearance of this granulation would suggest uniform dispersion, but microscopic analysis shows that frequently this is not so. By alternate pressing and warming thin sections, it is possible to obtain microsections which split in a way similar to mica, giving lamellas less than 0.001 mm. thick which appear to have been under different tensions. Such a structure may be obtained in a particularly effective way by mixing on a mill pale crepe and crepe contg. gas black, under which conditions the laminated structure becomes finer with the time of milling, but regardless of the time of milling, the mixt. fails to become homogeneous, alternate lamellas of the 2 components remaining visible. C. C. DAVIS

Coagulation phenomena in Hevea latex. VII. Phenomena in alkaline latex. OTTO DE VRIES AND N. BEUMÉE-NIEUWLAND. *Arch. Rubbercultuur* 12, 454-64(1928). (In English 465-71); cf. C. A. 22, 698.—The power of coalse to coalesce flocks in B-mixt. is destroyed not only by heating, by disinfectants and by acidifying to the 2nd liquid zone (cf. C. A. 18, 482; 19, 419) but also by making the

latex alk. Fresh undild. latex loses its coalescing power immediately by the addn. of 0.4 *N* NH_4OH or 0.04 *N* NaOH , and the addn. of 0.1 *N* NH_4OH or 0.35 *N* NaOH destroys its coalescing power in approx. 1 hr. Acidification of the mixts. shortly after addn. of the alkali only partly restores the coalescing power. Accordingly latex preserved in the ordinary way with NH_3 has lost its coalescing power. With the aq. ext. from coagulum obtained with EtOH , the limits at which the coalesce is destroyed are at 0.15 *N* NH_4OH and 0.015 *N* NaOH . The coalesce in exts. is destroyed at a limit of p_{H} 8, both with NH_4OH and with NaOH . Around this limit the coalescing power is lost gradually, and the larger the dose the more rapid is this loss. The acidity of latex, its content of NH_4MgPO_4 , and other factors also influence these phenomena. Addn. of AcONa up to 10 g. per 100 cc. to dild. or undild. latex does not decrease the coalescing power, while the alky. increases only from p_{H} 6.4 to 7, i. e., fails to reach the limit of p_{H} 8 mentioned above. C. C. DAVIS

Preserving latex with borax. N. BEUMER-NIEUWLAND. *Arch. Rubbercultuur* 12, 441-52(1928). (Summarized in English 453).—Borax may be used as an anticoagulant, for which purpose 1.2-1.5 g. per l. of latex is recommended. As a preservative, at least 30 g. per l. must be used. With an addn. of 20-25 g. per l., decompn. of the latex is inhibited, but a layer of rubber seps. on the top and a marked odor of glue becomes evident, indicating that the latex has not been rendered completely stable. Latex contg. borax has a lower viscosity than the corresponding latex without borax. Rubber prepd. from latex preserved with borax dries more slowly than rubber made under the same conditions but without borax. When latex is treated with borax and then kept for different times before coagulation, the rate of vulcanization of the rubber is slower than the corresponding rubber without borax up to about 2 weeks of preservation before coagulating. After allowing latex to stand over 2 weeks before coagulation, the rate of vulcanization of the rubber increases again until it eventually approaches the normal rate. In a similar way, the viscosity of rubber from latex contg. borax is lower than rubber from latex without borax, provided that the rubber is coagulated within a few days after addn. of the borax. If the latex is kept a long time with borax before coagulation, the viscosity of the resulting rubber increases until it reaches that of rubber from latex contg. no borax. Rubber prepd. from latex contg. borax is more plastic than the corresponding rubber from latex without borax. C. C. DAVIS

Chemical analysis applied to the selection of Hevea. A. W. K. DE JONG. *Arch. Rubbercultuur* 12, 472-501(1928). (Summarized in English 502-3).—The expts. represent the beginning of a systematic attempt to develop a method for foreseeing the yield and the quality of rubber from a given *Hevea* tree. Extn. of the blades of leaves with C_6H_6 and detn. of the rubber content showed very little difference between trees with a high yield and those with a low yield. Rubber extd. in this way from the stalks contained only about 80% hydrocarbons and the product oxidized easily, in fact accelerated the oxidation of crepe rubber, resembling the product obtained by exposing rubber solns. in quartz vessels. From the acetone and alc. exts. of the leaves a cryst. substance which m. 278-80° was obtained. Antioxidants are also present in the leaves. C. C. DAVIS

Extraction of gutta-percha leaf. A. W. K. DE JONG. *Arch. Rubbercultuur* 12, 540-55(1928). (Summarized in English 556-7).—Gutta-percha cannot be obtained by mech. methods from fallen leaves. The latter have the highest content of gutta-percha, and so expts. were started to det. whether a relatively pure product can be obtained by extn. of the fallen leaves. In preliminary expts., the addn. of the antioxidant of rubber to trunk gutta and to leaf gutta increased the resistance of the former to heating up to 90-100° but not that of the latter. By extn. with EtOH and then with acetone (to which leaf antioxidant had been added), or by extn. with C_6H_6 to which leaf antioxidant was added, a product was obtained which was extremely durable when heated up to 90-100°. When the powd. leaf was first boiled in AcOEt , and then extd. with C_6H_6 , a product was obtained which even without the addn. of an antioxidant was extremely durable when heated up to 90-100°. This indicates that the antioxidant is not extd. by AcOEt , though upon purification of the antioxidant ext. of the leaf by AcOEt , the greater part dissolved. When purified with acetone or EtOH , the C_6H_6 and benzine exts. of fallen leaves showed antioxidant power. Purification with AcOEt at normal temp. gave a product with little durability, and dry heating of the benzene ext., if already purified, gave a readily oxidizable product. For extn. on a large scale this method cannot therefore be used, but it is possible that a successful method would comprise purification of the powd. leaf with EtOH with addn. of antioxidant, and subsequent extn. with C_6H_6 or benzine contg. antioxidant. C. C. DAVIS

Sodium fluosilicate [in the production of raw rubber]. N. H. VAN HARPEN. *Arch.*

Rubbercultuur 12, 423-31(1928). (In English, 432-40); cf. van Dillen, Knaus, Kraay and Riebl, *C. A.* 22, 2682; van Harpen, *C. A.* 22, 1928.—A comparison of crepes made with the use of HCO_2H and Na_2SiF_6 , resp., as coagulants showed that Na_2SiF_6 gives the better colored crepe. Where the differences were small and close comparisons had to be made, it was found that the Lovibond tintometer was especially good, 0.5 g. of rubber being dissolved in 10 cc. of xylene. The quality of the crepe made with Na_2SiF_6 was as satisfactory as that with HCO_2H , for though the viscosity was lower and the tackiness greater, these were not abnormal. The rate of vulcanization, tensile strength and slope were normal. Na_2SiF_6 can be used as a coagulant for rubber for sole crepe, the properties of the latter being fully as satisfactory as sole crepe made under similar conditions but with HCO_2H . Further expts. show that an appreciable loss of rubber is not to be feared when Na_2SiF_6 is used as a coagulant, in fact with latex with a 20% rubber content a higher final wt. may be obtained because of greater absorption of smoke. This greater absorption probably depends upon the greater softness of the coagulum obtained by coagulation with Na_2SiF_6 . The low susceptibility to molds of sheet rubber prep'd. with Na_2SiF_6 , attributed by certain investigators to the influence of the Na_2SiF_6 , is probably a result of the greater absorption of disinfectant components in the smoke.

C. C. DAVIS

A new rubber dough and solution mixer. ANON. *India Rubber J.* 76, 536(1928).—A new mixer (made by Baker, Perkins, Ltd., Peterborough, England) is described and illustrated, the most novel features of which are a pair of horizontal blades sufficiently powerful to allow the use of unmilled rubber and a special feed pump which controls the quantity of solvent and its rate of addn. It is made in capacities of 22, 44 and 110 gals.

C. C. DAVIS

Proportion of sulfur to be added to diphenylguanidine mixtures. W. B. WIEGAND. *Kautschuk* 4, 156(1928).—Comments on a paper by Esch (cf. *C. A.* 22, 2492). The optimum proportion of S to be used in mixts. with diphenylguanidine as accelerator depends not only upon the general character of the mixt. but depends specifically upon the proportion of diphenylguanidine.

C. C. DAVIS

Proportion of sulfur to be added to diphenylguanidine mixtures. WERNER ESCH. *Kautschuk* 4, 157(1928).—A reply to Wiegand (cf. preceding abstr.).

C. C. DAVIS

Important observations on rubber mixtures containing gas and lamp blacks. WERNER ESCH. *Gummi-Ztg.* 43, 75 8(1928).—Various expts. are described which show the difference between gas blacks and lamp blacks in rubber mixts. The superiority of the gas blacks was so marked that it was possible to replace a considerable proportion of new rubber by reclaimed rubber and still have the quality of the mixts. contg. the reclaimed rubber and gas black as good as the corresponding mixts. with new rubber and lamp black. In a series of mixts. where new rubber was replaced progressively by reclaimed rubber and the other ingredients, including the gas black, altered so that theoretically the same formula was maintained, the quality of the vulcanized mixts. became progressively poorer as the reclaimed rubber content increased.

Heat transmission. COLIN MACBETH. *Trans. Inst. Rubber Industry* 4, 137-47 (1928).—A review and discussion dealing with the importance of heat transmission in the rubber industry, including the part it plays in softening rubber preparatory to washing, washing rubber, drying washed rubber, masticating rubber, mixing, calendering, spreading and vulcanization by various methods. A general discussion follows the paper.

C. C. DAVIS

The absorption of light by stretched and by unstretched rubber and by isoprene. M. KRÖGER AND H. STAUBE. *Univ. Leipzig. Gummi-Ztg.* 43, 22, 24(1928); cf. *C. A.* 22, 3066.—The absorption of ultra-violet light by isoprene, isoprene rubber, unstretched and stretched raw and vulcanized rubber was measured by means of a quartz spectro-

graph to ascertain in what way the absorption of light is dependent upon the state of tension. In all cases the transparency of the stretched rubber samples was greater than that of the unstretched samples, especially with stretched membranes. The transparency of artificial rubber was greater than that of isoprene of the same thickness. Vulcanized rubber had very little transparency. The transparency was judged by the beginning of continuous absorption, not by individual absorption bands. The transparency of stretched raw or slightly vulcanized rubber membranes to ultra-violet light makes possible the manuf. of rubber lenses for ultra-violet radiation, in which case the lenses could be made as a cell contg. water or alc. C. C. DAVIS

Standard methods of analysis of rubber goods. A. E. LEIGHTON. *Australia Dept. of Defence Munitions Supply Board*, May 1926, 11 pp.—A procedure which involves standard methods is outlined for the analysis of rubber goods, including the prepn. of the sample, and detn. of the AcMe, CHCl_3 and alc. KOH exts., free S, total S (inclusive and exclusive of BaSO_4), ash, insol. ash, Pb, Sb, Sb in ash, Fe and Al, Zn, Ca and Mg, Mg, S in ash, BaSO_4 , BaCO_3 and rubber hydrocarbons. C. C. DAVIS

The manufacture of hard rubber dust. MAX RATHKE. *Gummi-Ztg.* 42, 2688-9 (1928).—A description of present developments. C. C. DAVIS

Process for rubberizing fabrics containing copper and manganese. ERICH WURM. *Gummi-Ztg.* 42, 2476-7 (1928).—The patented process of Esch (cf. German Patent 461,134) has no practical importance, and may lead to disastrous results in manuf. C. C. DAVIS

Process for rubberizing fabrics containing copper and manganese. WERNER ESCH. *Gummi-Ztg.* 42, 2477-8 (1928).—An answer to Wurm (cf. preceding abstr.). C. C. DAVIS

Process for rubberizing fabrics containing copper and manganese. ERICH WURM. *Gummi-Ztg.* 42, 2580-1 (1928).—Answer (cf. preceding abstr.). As judged by tests in air at 70° , rubber vulcanized with tetramethylthiuramdisulfide deteriorates rapidly if treated with Cu salts before vulcanization, but if treated after vulcanization their deterioration is normal. C. C. DAVIS

Molded rubber goods. R. CLARK. *Trans. Inst. Rubber Industry* 4, 186-9 (1928).—A discussion of current problems. C. C. DAVIS

Rubber as a floor covering. J. KIRKWOOD. *Trans. Inst. Rubber Industry* 4, 148-60 (1928).—A general review and discussion of present developments, including the various ingredients used and their characteristic effects, and the methods of manuf. of different types of flooring. A general discussion follows the paper. C. C. D.

Some experiments on the manufacture of rubber road blocks. J. G. FOL AND F. C. VAN HEURN. Gov. Rubber Inst., Lab. Building Materials and Lab. Tech. Botany, Delft. *Bull. Rubber Grower's Assoc.* 10, 608-20 (1928).—A new type of paving block is described which consists of a base of hard rubber, which may contain stone or sand, on which is superposed a resilient cap for the wearing surface. This cap may be vulcanized on the hard base by an intermediate semi-hard layer. The base material can be made by addn. of the stone to the uncured mixt. or by the Cresson method, using latex (cf. Brit. Pat. 191,474; C. A. 17, 3084). Various phys. tests of blocks made by different methods and of different compns. are described. The use of ordinary rubber mixts. instead of latex is preferable because (1) the drying operation is avoided; (2) more nearly homogeneous mixts. are obtained; (3) ingredients impossible to use in latex can be used, and (4) low-grade rubbers can be used. Typical formulas for the base, intermediate and surface layers which have given particularly good results are shown, and the technic for the construction and vulcanizing is described. C. C. D.

Rubber solvents, varnishes and coatings. R. ASSMAN. *Farbe u. Lack* 1928, 396, 411, 426-7.—Among the newer solvents for rubber are ethylene dichloride and tetrachloroethane. When 100 g. rubber are treated with 2.5 l. solvent, ethylene dichloride, tetrachloroethane and chloroform dissolve 99.5, 75.6 and 74.9%, resp. Hydrogenated naphthalenes are relatively cheap and several formulas using them are given. Their chief advantage are favorable evapn. rates. A typical formula is 1 kg. of rubber fused in 2 kg. of rosin, to which are added 1 kg. of linseed oil and 1 kg. of tetralin or hydroterpin. A short review of English and German patents of products similar to "Thermoprene" is given. G. G. SWARD

The question of priority for the discovery of thermoplastic products from rubber, which resemble gutta-percha, balata and shellac, and their systematization. F. KIRCHHOFF. *Kautschuk* 4, 142-9 (1928).—A crit. review of the literature shows that the gutta-percha or shellac-like products obtained by Fisher from raw rubber by treatment with H_2SO_4 and sulfonic acids (cf. C. A. 21, 195; 22, 887, 2291) are essentially the same products which have previously been described by Harries (cf. C. A. 14, 1908)

and by K. (cf. C. A. 15, 960; 16, 1885; *Kautschuk* Jan. 1926; Austrian Patents 90,775 (1921) and 93,480 (1922)). Priority for the discovery of sulfo-rubbers is therefore with the German investigators. From the technical point of view the application of these substances (cf. Canadian Patent 256,567 (1925); U. S. Patent 1,805,180 (1926)) represents important progress, since the use of solvents is avoided. Thermoplastic substances in general are discussed, an attempt being made to classify these substances in 4 groups, according to their method of prep'n. and the reagent used: (1) *sulfo-cyclorubbers*, comprising the H_2SO_4 -rubbers of Harries and of Kirchhof and the sulfonic acid-rubbers (thermoprenes) of Fisher; (2) *thermocyclorubbers*, comprising the mono-cyclorubber of Harries and the hydro-cyclorubber and the poly-cyclorubbers of Staudinger; (3) *photo-cyclorubbers* of Porritt and of Asano, and (4) *contact-polymer rubbers*, comprising the metallic halide-rubbers of Bruson and the Cl_2CCO_2H -rubber of the B. F. Goodrich Co. The methods of prep'n., phys. and chem. properties and probable chem. constitution of these substances are tabulated. C. C. DAVIS

Pressure vulcanization. F. H. AMENDE. *Trans. Inst. Rubber Industry* 4, 170-80 (1928).—A general review and discussion dealing with the historical aspects and with different types of vulcanizers. Diagrams and graphs are included. A general discussion follows the paper. C. C. DAVIS

Vulcanization problems. ALFRED A. PERKS. *Trans. Inst. Rubber Industry* 4, 123-36 (1928).—A review and discussion dealing with the dispersion of S in rubber, temps. used for vulcanizing, thermal characteristics of vulcanization, operation of vulcanizers, conditions to be satisfied during vulcanization, curing in different types of vulcanizers, varying degrees of cure depending upon the size of the product, and times of vulcanization. A general discussion follows the paper. C. C. DAVIS

The vulcanization of rubber. NICHOLAS BACON. *India Rubber J.* 76, 459-64, 504-7, 542-5 (1928).—See C. A. 22, 3804. C. C. DAVIS

The vulcanization of rubber with metallic sulfides and an ultra-accelerator. TAKEJI YAMAZAKI. *J. Soc. Chem. Ind. Japan* 31, 165B (1928); *Gummi-Ztg.* 43, 190.—The expts. deal with the influence of ZnS , $(NH_4)_2S$, PbS , CdS , Al_2S_3 and As_2S_3 on the vulcanization of mixts. contg. an ultra-accelerator. It was assumed that the presence of an ultra-accelerator would, in conjunction with the small proportion of free S in the sulfide, be capable of inducing vulcanization. Seven mixts., contg. besides smoked sheets 100, and diethylaminodiethylthiocarbamate 2, the following quantities of ZnO and sulfide, were prep'd.: (1) ZnO 30; (2) ZnO 10, ZnS 20; (3) ZnO 20, $(NH_4)_2S$ 10; (4) ZnO 10, PbS 20; (5) ZnO 10, CdS 20; (6) ZnO 10, Al_2S_3 20; (7) ZnO 10, As_2S_3 20. The mixts. were heated 30 and 110 min. at 3 atm. Mixts. (1), (3) and (6) were not cured at all, mixts. (2) and (4) were partly cured, and mixt. (5) was definitely cured. Of the sulfides which had led to a certain degree of cure, the ZnS contained 2.33% free S, PbS 0.02% free S and CdS 1.60% free S. When the CdS was first extd. with acetone, the vulcanizate had extremely poor phys. properties. Conclusion: The phys. properties of the 6 vulcanizates depended chiefly upon the proportion of free S in the metallic sulfides and only to a small extent on the metallic sulfide itself. The samples of mixts. contg. a sulfide which were thoroughly cured contained about the same proportion of free S as mixt. (1) contg. no sulfide, though their phys. properties were different. C. C. DAVIS

The discoloration of zinc oxide during vulcanization. J. A. ROBERTSON. *Trans. Inst. Rubber Industry* 4, 190-3 (1928).—Experience has shown that when ZnO is darkened by H_2S it also darkens during vulcanization, but no systematic expts. on this problem are on record. This induced a closer examn. of the problem. Samples of ZnO contg. 0.16, 0.20 and 0.013% PbO , resp., all darkened to the same extent when exposed to H_2S or when heated in a rubber-S mixt. After extn. with water and drying, the first 2 samples darkened still more, whereas the 3rd sample was unaffected. Pure $PbSO_4$ was, when dry, unaffected by H_2S , but when moist it was darkened, probably because of the equil. reaction: $PbSO_4 + H_2S \rightleftharpoons PbS + H_2SO_4$, in which case removal of the H_2SO_4 would result in complete conversion of the $PbSO_4$. Two intimate mixts. of ZnO and $PbSO_4$: (1) a thin paste dried, and (2) a dry-ground mixt., were each treated with H_2SO_4 . Only mixt. (1) darkened, probably because while wet the following reaction takes place: $PbSO_4 + Zn(OH)_2 \rightleftharpoons 2ZnSO_4 + PbO \cdot H_2O$. The same relative effects were obtained after the mixts. had been ignited. Samples of basic Pb sulfate were darkened by H_2S . $ZnSO_4$ is very difficult to ext. from ZnO , suggesting that it is not present as such, but is formed by the water from $Zn(OH)_2$ and $PbSO_4$. Mixts. of ZnO and $PbSO_4$ and of ZnO and PbO (in the same proportions) were brought to equil. in water. The filtrate from the ZnO - PbO mixt. contained considerable Pb , whereas that from the ZnO - $PbSO_4$ mixt. contained almost

none. Absence of Pb in filtrates from samples of com. ZnO depends therefore upon the fact that after treatment with water it is present as basic Pb sulfate and not as PbO. The expts. indicate that darkening of ZnO by H₂S results from the actions of the latter on basic Pb sulfate, and that in com. ZnO the Pb is present chiefly as PbSO₄ with traces of basic Pb sulfate and PbO. By treatment of com. ZnO with water, PbSO₄ is converted into basic Pb sulfate, which is darkened by H₂S. This change is so easily brought about that exposure of com. ZnO to air soon makes it susceptible to darkening by H₂S in virtue of the atm. moisture. C. C. DAVIS.

The effect of flour in rubber mixtures vulcanized with sulfur. RUDOLF DITMAR. Kautschuklaboratorium Graz. *Gummi-Ztg.* 43, 191(1928).—Expts. show that various flours, including wheat, rye, barley, oat, corn, buckwheat, rice, bean, pea and potato flour, are excellent plasticizing agents, their plasticizing power depending upon the particular flour and its fineness. As a result, flours facilitate the mixing of fillers, particularly high proportions of gas black. They are suitable for various mixts. provided they are not vulcanized at too high a temp., decompn. of the flour occurring above a certain range. This renders ultra-accelerators particularly useful when flour is used. The unfavorable effect of flours on the aging of vulcanized mixts. can be completely overcome with preservative agents (antioxidants). Flour is unsuitable for use in mixts. vulcanized with S₂Cl₂. C. C. DAVIS

Rubber-proofing of fabrics (MUNRO) 25. Determining total solids [in latex] (KRAUSE) 7. Developments in machines for testing fibers, yarns and fabrics [rubber] (SCOTT) 25. Single texture proofing (RYDINGS) 25. Fossil rubber bark in ancient brown coal (GOTHAN) 8. Electric conduction in hard rubber (RACE) 4. S in highly dispersed form [for rubber compositions] (U. S. pat. 1,688,357) 18. Molds for plastic materials [rubber] (Fr. pats. 638,010 and 638,008) 18.

Stabilized latex containing blood protein. MORGAN R. DAY (to Rubber Latex Research Corp.). U. S. 1,689,581, Oct. 30.

Softening and preventing aging of rubber. G. FESSLE and TECHNISCHE CHEMIE-KALIEN Co. GRS. Brit. 286,171, Sept. 21, 1927. A softening and "anti-aging" ingredient for use in the manuf. of rubber goods is prepd. by extg. the phenolic constituents and aromatic bases contained in tar produced by the distn. of coal, lignite, shale or peat, or in distillates from such tars, and subsequently removing any undesirable light oils. "Methylated spirits," MeOH, EtOH, acetone or EtOAc or their mixts. which may be dild. with water are suitable solvents and soda lye and C₂H₅ may also be used in some cases. The oils obtained are preferably heated to 135–50°, allowed to cool and then added to rubber mixings or scrap rubber in the proportion of 5–10%.

Roller apparatus for mixing and sheeting rubber. L. GRAFFE. Brit. 285,712, June 22, 1927.

Rubber-mixing apparatus. FERNLEY H. BANBURY (to Farrel-Birmingham Co.). U. S. 1,689,990, Oct. 30.

Preserving rubber. L. B. SEBRELL (to Goodyear Tire & Rubber Co.). Brit. 286,288, March 3, 1927. The aging qualities of rubber are improved by adding to the mixt. before vulcanization, a reaction product of an aldehyde and an amine (such as the product from aniline and acetaldehyde) which is formed in a cold reaction mixt. and is not an active vulcanization accelerator. Cf. C. A. 22, 3551.

Preserving rubber articles during storage. THOMAS M. RECTOR (to Vitapack Corp.). U. S. 1,688,355, Oct. 23. Inner tubes for tires or other closed rubber articles are filled with N, CO₂ or other inert gas and also surrounded by inert gas within a sealed container which may be made of sheet metal.

Deposition of rubber. SOCIÉTÉ DU CAOUTCHOUC "ANODEX." Fr. 638,504, Nov. 27, 1926. A partition of glass or ceramic material or cloth is placed between the cathode and the support for the electrophoretic deposition of rubber to keep the rubber free from gas bubbles formed at the cathode. Cf. C. A. 22, 3551.

Reinforced hard rubber. WM. B. WESCOTT (to Rubber Latex Research Corp.). U. S. 1,689,570, Oct. 30. In forming a material suitable for battery jars, insulation, etc., comminuted hard rubber is admixed with disintegrated partially cured rubber, S, fiber such as reclaimed cotton, and with rubber latex, and the mixt. is dried, molded and vulcanized.

Bonding rubber to metal. HAROLD GRAY (to B. F. Goodrich Co.). U. S. 1,689,628, Oct. 30. A vulcanizable rubber compn. is superposed on steel or other metal with an interposed film comprising S chloride in direct contact with the metal and vulcanizing is effected by heating at a usual vulcanizing temp. Cf. C. A. 22, 3318.

Rubber articles. "COGEDEX" COMPAGNIE GÉNÉRALE D'EXPLOITATION. Fr. 638,304, July 27, 1927. The rubber gum, after incorporation of the S and fillers, is put directly into the mold for vulcanization.

Rubber articles formed by dipping. DUNLOP RUBBER CO., LTD., and D. F. TWISS. Brit. 285,938, Oct. 22, 1926. Before dipping a mold in latex compn. or the like, the mold is first coated with gelatin or the like contg. a coagulant such as Na fluosilicate, HOAc, or a salt of Ca, Mg, Zn or Al. The mold or bath is agitated to make the deposit more uniform.

Molded rubber articles formed by dipping. ANODE RUBBER CO., LTD. Brit. 285,844, Feb. 23, 1927. The mold is heated during the intervals between successive dippings in a dispersion of rubber, and may also be heated during the dippings, *e. g.*, by a circulating heating fluid or by elec. current.

Molded articles of cork and rubber composition. RAOUL GRIMOIN-SANSON and HERMAN DANIEL. U. S. 1,688,491, Oct. 23. Tires, tire treads or other molded vulcanized articles are formed of a mixt. comprising rubber, powd. cork, emery and a vulcanizing agent.

Rubber threads, tapes and strips. INDIA RUBBER, GUTTA PERCHA & TELEGRAPH WORKS CO., LTD., AND E. J. SMITH (known as E. J. Edgar). Brit. 286,066, Feb. 10, 1927. A sheet of unvulcanized rubber is applied to a supporting surface such as tin-foil to which it will lightly adhere after vulcanization, is vulcanized, cut into threads or strips, and then stripped from the supporting surface. An app. is described.

Plastic moldable composition containing rubber. CARL KULAS. U. S. 1,688,500, Oct. 23. A mixt. of comminuted rubber and dissolved "resol" (an initial condensation product of CH_2O and phenol) is rapidly calendered to expel volatile constituents and render the mass homogeneous, the latter is seasoned at a moderate temp. (suitably about $30-40^\circ$) which is maintained const. during the seasoning and the material is dried. It is suitable for *elec. insulation*, etc.

Treating waste rubber. RHEINISCHE GUMMI- UND CELLULOÏD-FABRIK. Fr. 638,396, July 28, 1927. Waste rubber is powdered and added to a non-volatile nitro-cellulose solvent such as triphenolphosphate, palatinol, acetanilide, ethylacetanilide or plastol, which lowers the m. p. of the camphor contained in the rubber, after which the mass is submitted to heat and pressure.

Composition for sealing punctures in pneumatic tires. ERNEST E. BOARD. U. S. 1,690,051, Oct. 30. A mixt. is formed from bran 1, flaxseed meal 1, corn sirup 2 parts, and 2 parts of an anti-freeze soln. contg. CaCl_2 27.5%, and K chromate 1 part, with water to make a pasty compn. suitable for introducing into a tire.

Rubber substitute. LOUIS LAURIN. Fr. 638,559, Dec. 11, 1926. An elastic compd. which may be used for pneumatic tubes, etc., is made from chrome-tanned colloids with which a double sulfate of Al and K, glycerol and, if necessary, formol are combined. In an example 100 parts of gelatin, 5 of $\text{K}_2\text{Cr}_2\text{O}_7$, 2 of the double sulfate, 80 of water, 90 of glycerol and 3 of formol are used.

Synthetic rubber. I. G. FARBENIND. A.-G. Brit. 286,272, March 2, 1927. Polymerization of hydrocarbons such as isoprene, butadiene and dimethylbutadiene is effected in an aq. colloidal soln. soln. or suspension contg. one or more electrolytes (which may in general be acids, bases or salts, either inorg. or org., with good elec. conductivity), either in the presence of O, ozone or substances which produce them or in an inert atm. such as N or CO_2 ; *e. g.*, dimethylbutadiene is agitated with egg albumin and Na phosphate in water at a temp. of 80° . Numerous other examples are given. Cf. C. A. 22, 4274.

Vulcanizing rubber. CECIL J. T. CROMSHAW and W. J. S. NAUNTON (to British Dyestuffs Corp., Ltd.). U. S. 1,687,861, Oct. 16. Di-xylylguanidine is used as an accelerator.

Vulcanizing rubber. WINFIELD SCOTT (to Rubber Service Laboratories Co.). U. S. 1,688,755, Oct. 23. A vulcanized product of good "age resisting" properties is obtained by heating rubber and S together in the presence of a reaction product of guanidine or a diaryl-substituted guanidine and hydroquinol or other hydroxy deriv. of benzene. U. S. 1,688,756 specifies the use of *p*-dimethylaminophenyl-*p*-phenetidyl guanidine as a vulcanization accelerator. U. S. 1,688,757 specifies the use of *p*-dimethylaminodiphenylguanidine and U. S. 1,688,758 specifies *p*-dimethylaminophenyl-*o*-tolylguanidine.

CHEMICAL ABSTRACTS

Vol. 23.

JANUARY 20, 1929

No. 2

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

A laboratory apparatus with a conductometric indicator for studying saturation and filtration. VL. STANĚK AND K. SANDERA. *Listy Cukrovar.* 47, 33-7(1928).—A description. FRANK MARESH

Vacuum tubes as oscillation generators. D. C. PRINCE AND F. B. VOGDES. *Gen. Elec. Rev.* 31, 678(1928). C. G. F.

A new iodosobenzene (iodoso-iodoxybenzene) electrode for the determination of p_{OH} and of p_{H} . FELIX GROSSMAN. *Bull. soc. chim.* 43, 1063-72(1928).—See C. A. 22, 4111. E. H.

A new electrical instrument for marking various objects, notably of rubber, and its application to vulcanization. L. GRAND. *Caoutchouc & gutta-percha* 25, 14195(1928).—The marker is of special alloy and can be heated electrically and const. temps. from 40° to 800° can be obtained. C. C. DAVIS

Electric water heating. H. C. WILDER, *et al.* *Elec. World* 92, 1039-41(1928).—Results are recorded of 2 yrs.' study of American and European low-wattage, high-storage-capacity elec. heaters. C. G. F.

Control of the moisture content of air in industrial driers. ANON. *Apparatebau* 40, 233-4(1928).—Description of the "Ranarex" app. J. H. MOORE

Improvements in the method of Hempel-Drehschmidt. H. VAN DAM. *Ing. chim.* 16, 124-7(1928).—A description of an apparatus permitting the use of numerous absorbents for gas analysis. P. THOMASSET

Method for heating liquids containing ether. BIRYUKOV AND PODSHIVALIN. *Masloboino Zhirovoe Delo.* *Oil & Fat Ind.* (Russia) 1928, No. 1, 19-20.—Elec. resistance elements calcd. to produce a temp. of 100° to 105° are used for drying ovens and elements calcd. for 45-50° for extractors. The elements are completely enclosed. Air is circulated and heated to about 100-105° in drying ovens and a water bath is provided for extrn. flasks. All fire hazards are eliminated by this arrangement. A. A. B.

The classification of acetylene generators. ALFRED SCHROEDER. *Acetylen in Wissenschaft u. Ind.* 31, 49-54, 68-9, 115-6(1928).—A discussion and improved scheme of classification of the various types, based on operating principles. F. S. GRANGER

Simple and low-cost gas-pressure regulator. L. MULLER. *Compt. rend. soc. biol.* 99, 1065-8(1928).—The construction and operation of the app. are illustrated and described. L. W. RIGGS

The significance of the surface for the escape of steam in evaporators. HANS MELHARDT. *Chem. App.* 15, 181-3, 210(1928).—Several types of evaporators are shown with tables showing the surface area of the soln., the amt. of steam, the vol. per unit of surface area and the speed of escape at given pressures. J. H. MOORE

Calculation of the allowable stresses in the walls of vessels manufactured from plates of wrought iron, steel, copper and aluminum. HANS MELHARDT. *Chem. App.* 14, 249-51, 263-5(1927); 15, 4-6, 15-8, 37-9, 63-6, 87-9, 110-3, 136-9, 147-50, 171-3, 207-10, 243-6(1928).—Summary of the regulations on materials and construction of stationary boilers by the German steam boiler committee, with 10 cuts, 2 charts, 15 tables and many mathematical formulas. J. H. MOORE

The fodder value of dried grass [drying apparatus] (SUTTON) 12.

Thermometers. FRITZ HÖRNIG. Ger. 466,474, Apr. 23, 1926. A max. thermometer has a rigidly fixed ball at the top of the reservoir, just below the base of the capillary tube, to retain the column in its highest position until shaken.

Thermometers. FIRMA DR. HEINRICH GLOCKEL AND CURT BUNGE. Ger. 466,473, Apr. 13, 1927. An addnl. column of liquid with a special scale is provided on top of

the usual expanding column so that the readings can be taken without removing the expansion liquid from the medium under observation.

Distance type thermometer and corrugated capillary tubing suitable for use with same. HERMAN SCHLAICH. U. S. 1,691,133-4, Nov. 13. U. S. 1,691,135-6 also relate to structural features of thermometers.

Pyrometer construction. REPUBLIC FLOW METERS CO. (Electroflo Meters Co., Ltd.). Brit. 288,105, Nov. 4, 1927.

Pyrometers. HARTMANN & BRAUN A.-G. Ger. 466,476, Dec. 25, 1926. A heat radiation pyrometer is provided with a compensating arrangement to enable it to be adjusted for the temp. of the room.

Refractometer for oils or ether liquids. W. EVERITT. Brit. 286,753, Nov. 9, 1926.

X-ray apparatus. MONTFORD MORRISON. U. S. 1,690,906, Nov. 6.

X-ray spectrograph. ALEXANDRE DAUVILLIER. Fr. 637,650, Nov. 17, 1926. An x-ray spectrograph is described which can be used for the spectral analysis of x-rays of short wave length, and of medium wave length and cryst. analysis.

Electron-discharge device. HARVEY C. RENTSCHLER (to Westinghouse Lamp Co.). U. S. 1,691,446, Nov. 13. An electron-emitting cathode is coated with an alk. earth metal carbonate, the plate and cathode are sealed in an envelope which is then evacuated, and the filament is then heated to decomp. the coating to oxide and while the filament is still heated a metallic "clean-up agent" such as "misch metal" is vaporized within the envelope.

Household filter. HENRY A. VALLEZ (to Vallez Rotary Filters Co.). U. S. 1,690,958, Nov. 6.

Tap filter for liquids. A. HALES. Brit. 287,351, May 17, 1927.

Continuous pressure filter. CHARLES ST. C. BURNS (one-half to Foist Kay). U. S. 1,691,867, Nov. 13.

Rotary vacuum drum filter with associated pressure rolls. RECKITT & SONS, LTD., AND E. H. HALL. Brit. 287,725, April 7, 1927.

Air filter with a rotatable drum. HANS E. BIRKHOLZ (to National Air Filter Co.). U. S. 1,690,813, Nov. 6.

Filter (of nested metal sleeves) for preventing backfiring in oxy-acetylene burners, etc. W. LITZ. Brit. 287,530, March 23, 1927.

Spiral filter for oil, etc. MARSHALL H. WARD (to Motor Improvements, Inc.). U. S. 1,690,564, Nov. 6.

Rotary filter for slurry, etc. R. A. ELTON. Brit. 287,694, Feb. 25, 1927.

Rake gear for sand and similar filters. C. R. B. BROWN. Brit. 287,692, Feb. 23, 1927.

Device for separating suspended particles from gases. OTTO HUBMANN (to Metallbank & Metallurgische Ges. A.-G.). U. S. 1,690,635, Nov. 6.

Apparatus for separating suspended particles from steam or other flowing gases by whirling or centrifugal action. HAGAN CORP. (J. Gordon & Co., Ltd.). Brit. 286,853, Feb. 9, 1927.

Device for separating dust from air currents by deflection. CHARLES A. WINSLOW AND ELBERT J. HALL. U. S. 1,691,536, Nov. 13.

Apparatus for separating suspended particles from a fluid stream. TIRAGE & VENTILATION MECANIQUE. Ger. 466,753, May 23, 1926. The stream is acted on by 2 oppositely directed vanes, the first forcing it against a sepg. wall arranged between the vanes.

Centrifugal apparatus for separating and washing solid substances. L. P. SHARPLES (to Sharples Specialty Co.). Brit. 287,056, March 12, 1927.

Centrifugal strainer for removing solids from various sludges. E. C. ELSMORE, H. J. HOLFORD and A. BISHOP. Brit. 286,855, Feb. 10, 1927.

Apparatus for separating solvents such as gasoline from sludges by treatment with water and sedimentation. BENJAMIN L. HARRISON. U. S. 1,691,000, Nov. 13.

Centrifugal apparatus for separating coal and "slime water" or other materials. A. KITTNAR (to Maschinenbau-Anstalt Humboldt). Brit. 287,442, March 18, 1927.

Apparatus for separating and classifying coal, pigments or other powdered or granular substances by action of air currents. R. LESSING. Brit. 287,262, Jan. 11, 1927.

Reciprocating table and air supply system for separating materials of different densities. R. PEALE, W. S. DAVIES and W. S. WALLACE. Brit. 287,184, Sept. 13, 1926. Air is forced up through material on a pervious reciprocating table.

Apparatus for gravity separation of oil and water or other liquids of different specific

gravities. WILLIAM G. G. P. LUMSDEN (to Rodway Stephens, *Liquidator*) U. S. 1,690,741, Nov. 6.

Apparatus for gravity separation of oil and water or other mixed liquids of different specific gravities. HENRY S. HELB-SHAW and ALBERT BEALE. U. S. 1,690,537, Nov. 6.

Apparatus for separating mixtures of water with benzene, benzine, etc. PASSAVANT-WERKE G. M. B. H. Ger. 466,988, Nov. 22, 1924. The float and the valve of the float-valve regulating the admission of the mixt. to a sepg. vessel are arranged at opposite ends of a double-arm lever.

Apparatus for automatically discharging liquid from a chamber to air-purifying or other devices. G. MURRAY and V. O. SIMPKINS. Brit. 287,244, Dec. 18, 1926. Gas supplied from a pressure cylinder, by chem. action or by electrolysis, may be used to cause continuous or intermittent discharge of liquid.

Apparatus for evaporating salt solutions, cellulose waste lye or other liquids. AKTIEBOLAGET SVENSKA MASKINVERKEN and E. G. ERIKSSON. Brit. 286,982, Sept. 6, 1927. A heating medium such as steam is passed through a hollow device carrying disk-like members, the lower part of which dips in the liquid to be evapd. and which may be rotated.

Apparatus for revaporizing liquefied gases. STUDIEN-GES. FÜR GAS-INDUSTRIE. Brit. 287,909, March 29, 1927.

Apparatus for testing the damping capacity of materials. O. FÖPPL and E. PERTZ. Brit. 287,500, March 22, 1927.

Apparatus for determining the moisture content of paper webs or other materials. SAMUEL S. AMDURSKY. U. S. 1,690,155, Nov. 6. Air is passed over the material being tested after adjustment of the air to a definite humidity and the humidity of the air is detd. after the passage.

Apparatus for mixing food materials or other dry and liquid materials. LIONEL TRUE. U. S. 1,691,535, Nov. 13.

Apparatus for mixing fluids in definite proportions. H. GROECK and F. JORDAN. Brit. 287,070, March 11, 1927. A pump controlling the supply of one fluid is electrically controlled by the flow of the other fluid. Numerous details of construction are described.

Apparatus for pasteurizing liquids in bottles. F. C. HIPWELL and W. B. AUSTIN. Brit. 287,605, Nov. 29, 1926.

Pump for acids, milk, "petrol" or other liquids. R. C. CROSS. Brit. 287,267, Jan. 18, 1927.

Cooling mercury pumps. ALLGEMEINE ELEKTRICITÄTS-GESELLSCHAFT. Fr. 637,739, Jul. 16, 1927. The cooling fluid does not come in direct contact with the walls of the pump.

Colloid mills and method of operation. FREDERICK J. E. CHINA. U. S. 1,690,667-8-9, Nov. 6. A film of material is subjected to the disrupting action of closely spaced surfaces of the app., one of which at least rotates relative to the other.

Rotary drum mill for pulverizing coal or other materials. LOUIS C. BONNOT (to Bonnot Co.). U. S. 1,690,712, Nov. 6.

Apparatus for testing hardness of materials by impact. W. E. BROWN. Brit. 288,009, March 3, 1927.

Charging device for vertical kilns, etc. E. SOBEX. Brit. 286,956, July 15, 1927.

Charging means for shaft retorts, especially for gas producers. Soc. ANON. J. ET A. MOUSSIAUX ET FRÈRES. Ger. 466,963, Apr. 29, 1925. Constructional details are given.

Gas producers and similar apparatus portably mounted. STUDIEN-GES. FÜR GAS-INDUSTRIE. Brit. 287,486, March 21, 1927.

Rotary gas washer. ZSCHOCKE-WERKE KAISERLAUTERN A.-G. Ger. 466,754, June 8, 1926. Small, freely movable fillers are arranged within larger, movable and perforated fillers.

Coating and lining metal pipes with concrete and bitumen. W. R. HUME and HUME STEEL, LTD. Brit. 287,656, Jan. 10, 1926. Mech. features.

Drying apparatus. SIEMENS-SCHUCKERTWERKE A.-G. (Fritz Müller, inventor). Ger. 466,256, Sept. 15, 1925. A steam-heated drier for lignite and like substances has a safety valve in the steam inlet pipe.

Apparatus for drying or "smoldering" loose material. OTTO DOBBELSTEIN. U. S. 1,690,444, Nov. 6.

Apparatus for drying granular materials by passing upwardly through a heater suspended in a gas. O. SÖDERLUND, T. GRAM and TECHNO-CHEMICAL LABORATORIES, LTD. Brit. 286,743, Oct. 7, 1926.

Electric conductor for sealing in hard glass. WM. BENJAMIN GERO (to Westinghouse Lamp Co.). U. S. 1,691,426, Nov. 13. An alloy of W 80 and Mo 20% is used.
 Device for pressure and temperature control. J. H. REINEKE. Brit. 286,742, March 11, 1927.

Steam tube heating system for digesters. H. KOCK and R. QUITT. Brit. 286,955, July 15, 1927.

Heat-exchange apparatus. W. H. ARMACOST (to Superheater Co.). Brit. 286,682, March 9, 1927.

Heat-exchange apparatus for liquids. C. W. STANCLIFFE. Brit. 286,757, Nov. 12, 1926.

Heat-exchange apparatus suitable for use with liquids or gases. GEORGE T. JACOBS (to Whitlock Coil Pipe Co.). U. S. 1,691,012, Nov. 6.

Heat-exchange apparatus suitable for use with oil or other liquids or gases. CHARLES B. GRADY. U. S. 1,690,108, Nov. 6.

Heat-exchange apparatus suitable for use with oil or other liquids. CHARLES H. POTTS (to Vickers, Ltd.). U. S. 1,690,501, Nov. 6.

Heat regenerator. GAS RESEARCH CO. Ger. 466,830, Jan. 20, 1926. Constructional details.

Blast heater. ASKANAI-WERKE A. G. (formerly Centralwerkstatt-Dessau) and CARL BAMBERG-FRIEDENAU. Ger. 466,628, June 1, 1924. In a gas blast-heating app. the combustion air is forced through an injector nozzle, thus drawing addnl. air with it into the gas.

Continuous tunnel oven of the direct flame type. J. WILLIAMSON. Brit. 287,623, Dec. 22, 1926.

Rotary annular plate oven. TROCKNUNGS-VERSCHWELUNGS UND VERGASUNGS. Ger. 466,342, June 3, 1925. Details of construction.

Furnace. J. S. CROSSLEY. Australia 8160, July 7, 1927. A furnace has a rotary grate composed of upstanding circular flanged bars of successively increasing diams. and a further series of equal diam. The fuel is fed in at the end having the smallest bar.

Gas furnace. FIRMA WILHELM RUPPMANN. Ger. 466,586, May 30, 1926; addn. to 464,692. The construction of the burner is improved.

Gas furnace. SOCIÉTÉ POUR L'UTILISATION RATIONNELLE DU GAZ (Surgaz). Fr. 638,945, Dec. 31, 1926. Construction of combustion chamber.

Gas furnaces. VEREINIGTE STAHLWERKE, A. G. Fr. 637,821, July 16, 1927. The gas and air used in gas-heated furnaces of the rotating type, having a flame parallel to the longitudinal axis of the furnace, are heated in regenerators heated by fresh air and gas.

Regenerative continuous-current gas furnace. FRIEDRICH SIEMENS A.-G. Ger. 466,693, Mar. 11, 1927. Addn. to 418,799. Constructional improvements.

Burner for gas furnace. REGNIER EICKWORTH. Fr. 638,801, Aug. 3, 1927. The air is propelled by a paddle wheel operated by the gas under pressure.

Shaft furnace. EMANUEL SOBEK. Fr. 637,437, June 28, 1927. The furnace is enlarged at one side for the descent of fresh charges.

Distillation furnace. JACK ARNOUL DE GREY. Fr. 639,059, Jan. 12, 1927. A vertical distn. furnace in which the matter to be distd. descends between the walls of a casing provided with gratings for evacuation of the distn. gas has vertically disposed heating bodies in the form of parallelepiped-shaped boxes easily accessible from the exterior.

Furnace of regenerative type. POETTER G. in b. H. Fr. 637,307, Mar. 21, 1927.

Rotary furnace. GEWERKSCHAFT SACHTLEBEN AND J. KÜPPERS. Brit. 286,590, March 5, 1927. The walls of an inner muffle are formed of a material of good heat cond. such as SiC, Cr silicide or Mo carbide, while the outer lining is of material of poor cond.

Annular rotary-hearth furnace. JOHN F. BAKER (to Westinghouse Elec. & Mfg. Co.). U. S. 1,691,367, Nov. 13.

"Car-bottom furnace." JOHN F. BAKER (to Westinghouse Elec. & Mfg. Co.). U. S. 1,691,368, Nov. 13.

Furnace for coal dust. JACQUES PIEDBOEUF. Ger. 466,464, Jan. 31, 1926. The coal dust is blown into the fire chamber by an air current.

Catalytic apparatus. PAUL GRENÉ. Fr. 637,648, Nov. 17, 1926. In app. for catalytic reactions where several heated catalysts work in series, such as in hydrogenation, the series of catalysts are used in duplicate and each series is placed end to end in a single vessel and is regenerated as a whole.

Atomizing liquids. ALBERT CHARBONNEAU. Fr. 638,992, Jan. 4, 1927. A

turbine atomizer for liquids having arms of unequal distribution of drops of the liquid on the arms is and means for a regular

Protector for the taps of cylinders containing li- gas. SOC. L'AIR
LIQUIDE (SOC. ANON. POUR L'ÉTUDE ET L'EXPLOITATION DES PR GEORGES CLAUDE).
Fr. 637,667, Nov. 19, 1926.

Apparatus for liquid treatment of bands or strips, particularly cinematograph films.
JOHANN J. F. STROCK. Ger. 466,979, Jan. 15, 1928.

Copper plate, thermocouple and voltmeter for indicating temperatures of articles in contact with the plate. HOWARD D. MATTHEWS (to Westinghouse Elec. & Mfg. Co.).
U. S. 1,691,247, Nov. 13.

Thermionic valve. SIEMENS & HALSKE A.-G. Brit. 288,180, April 2, 1927. A cathode core may be coated with an intermediate coating of BaO and then further coated with an alk. earth metal such as Ba or with an alloy of such metals. The valves may be highly exhausted or may contain a rare gas such as A.

Thermionic valves. RADIOTECHNIQUE. Brit. 287,867, March 28, 1927. Oxide cathodes have cores such as W or Pt not volatilizable at their working temp., coated with a more volatile metal such as Cu which may be applied in a thin layer electrolytically. Ni, Cr and Si also may be used in making the filament as an intermediate layer.

Thermionic valves and similar devices. NAAMLÖÖZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 286,970, May 7, 1927. One or more of the surfaces which space electrodes or other parts of the device which are maintained at different potentials are coated with enamel. A suitable enamel, m. 450°, may be formed of Pb oxide 72, B₂O₃ 15, silicic acid 7, ZnO 3, Sn oxide 2 and Al₂O₃ 1%. Various structural details are described.

Coating thermionic valve cathodes, etc. ALLGEMEINE ELEKTRICITÄTS-GEZ. Brit. 286,650, March 7, 1927. The process of Brit. 268,815 (C. A. 23, 1256) for producing metal coatings on oxide bases is modified by using metallic oxide, instead of, or in addn. to, powd. metal in the coating paste.

Thermostats. OTTO SCHINKEL. Ger. 466,477, Mar. 16, 1926. A tube has a long lever pivoted to this base. A long rod of small coeff. of expansion is adjustably fitted into a socket in the base of the lever so that when the tube reaches a min. temp. its contraction causes the end of the rod to tilt the lever to "make" the heating circuit.

Thermostatic switch. IRA E. MCCABE and RAYMOND W. ARMSTRONG (Armstrong to Arcless Contact Co.). U. S. 1,691,016, Nov. 6.

Thermostatic electric switch adapted for giving warnings of sudden rises in temperature. EDMOND HALF. U. S. 1,690,486, Nov. 6.

Thermostatic valve. H. J. YATES, M. HOWLETT & Co., LTD., and J. DOLPHIN. Brit. 286,831, Jan. 6, 1927.

Thermostatic valve for controlling flow of heating fluids. JAMES J. LAWLER (to Direct-Control Valve Co.). U. S. reissue 17,135, Nov. 13. A reissue of original pat. 1,555,592, dated Sept. 29, 1925.

Thermostatic valve for controlling the supply of gas or other materials. ADOLF BELER. U. S. 1,691,008, Nov. 13.

Thermostatic control for electric circuits of refrigerating apparatus, etc. JOSEPH F. SEIDEL. U. S. 1,691,448, Nov. 13.

Thermostatic apparatus for regulating dampers, etc. DANTE V. MAZZOCCO (to Surface Combustion Co.). U. S. 1,690,829, Nov. 6.

Thermostatic apparatus for regulating dampers of combustion apparatus, etc. WM. M. HEPBURN (to Surface Combustion Co.). U. S. 1,690,819, Nov. 6.

Thermostatic and time control device for electric circuits governing heating apparatus. GEORGE H. HART. U. S. 1,690,898, Nov. 6.

2—GENERAL AND PHYSICAL CHEMISTRY

GEORGE L. CLARK AND J. H. REEDY

American contemporaries—Arthur D. Little. JAMES F. NORRIS. *Ind. Eng. Chem.* 20, 1395-6(1928). E. H.

Jan Zawadzki. ANON. *Przemysl Chem.* 12, 553-60(1928).—An obituary with a bibliography of over a hundred publications by Z. A. C. Z.

Present and proposed activities of the Franklin Institute. HOWARD MCCLENNAN. *J. Franklin Inst.* 206, 735-70(1928). E. H.

Institute of physical and chemical research at Tokyo. JAN ZAWADZKI. *Przemysl*

Chem. 11, 289-94(1927).—This is largely a comparison of support to chemical and physical research and technology given in Japan and in Poland. A. C. Z.

Simple experiment on equivalent-weight determination. JOHN E. S. HAM. *Chemist-Analyst* 17, No. 4, 6(1928).—An expt. is described suitable for beginners, in which the vol. of H_2 evolved from a weighed quantity of Zn is detd. W. T. H.

System of volume chemistry of homogenous liquids. F. WRATSCHKO. *Pharm. Presse* 33, 321-4(1928).—An address. W. O. E.

Method of calculating constitution in volume chemistry. F. WRATSCHKO. *Pharm. Presse* 33, 341-4(1928). W. O. E.

The variation of viscosity with temperature. I. C. WALTHER. *Erdöl u. Teer* 4, 510-11(1928).—From the generalized observation that double logarithms of the viscosities of a given liquid, plotted against the corresponding temps., give a straight line, is derived the formula: $\log \log V = - (M(t - 50)/100) + \log \log V_{50}^\circ$. $V = 100$ (abs. viscosity/sp. gr.). M is the change in $\log \log V$ per degree for the material in question, found from viscosity detns. at any two temps. Thus, for a given oil, the relation of viscosity to temp., without which viscosity is of little significance with reference to lubricating value, is completely defined from 2 viscosity detns. instead of 3, as heretofore. F. S. GRANGER

The stoichiometric law of the constant and multiple proportions as a limit law. GUSTAV F. HÜTTIG. *Hochschulwissen* 4, 261-6, 317-22, 365-70; *Chem. Zentr.* 1927, II, 1925.—The conception that in chemistry the law of the const. and multiple proportions is valid, and that the chem. science is not concerned with facts that do not agree with this law, had to be maintained as long as the at. structure of the matter was based on it. Now since the existence of the atoms has been established by other means, this strict differentiation between chemistry and physics is no longer necessary. In considering solid substances in the first line, it can be demonstrated that the law of the const. and multiple proportions is only a limit law, which would be fulfilled, if only the directing forces in the crystals were acting without the heat motion disturbing the order and causing a no. of atoms to stray around among the atoms arranged in a lattice-like manner. The no. of these atoms is different for each kind of substance. An equil. results that at very low temps. comes very close to the ideal law, while at very high temps., the limit laws of physics free of chemistry may exist. Chem. stoichiometry and osmosis show many phenomena that favor the strict validity of the law of proportions; much neglected up to the present time are, however, the homogeneous phases of which it certainly cannot be asserted that one or the other principle prevails (cf. e. g., the mineral pandermite or an aq. LiBr soln.). Speculations concerning the equil. cannot be extended to the org. substances, which for the larger part do not represent stable systems. At first they may be strictly stoichiometrically constituted; sooner or later, however, an irreversible decompn. occurs. Finally, is considered the "active" state of the matter, which often continuously changes to a stable one and thus cannot claim a fundamental special position inside the conceptions given. G. SCHWOCH

The reflectivity of carbon between room temperature and 1500°. KURT WARMUTH. *Wiss. Veröffentlich. Siemens-Konz.* 7, 307-20(1928).—The reflectivity at room temp. for wave lengths 0.538 μ and 0.663 μ is 0.034 plus or minus 5%. At 1740° K. the value is 0.028. W. concludes that between these temps. the reflectivity of C is independent of the temp., and assumes that this independence continues at higher temps. With R equal to 0.028 the true temp. of the positive crater of the C arc is found to be 3740° K. It is probable that the reflectivity in the infra-red is higher. A new vapor-pressure curve is given for C, based on the temp. of 3740° K. for atm. pressure. The molar heat of sublimation for the pressure range 1-5 atms. and the mean temp. 3900° K. is calcd. to be 125.54 kg. cal. B. MILLER

The influence of the strength of molecular attraction on the internal friction and the conductivity of gas mixtures. HANS SCHMICK. *Physik. Z.* 29, 633-40(1928).—On account of the difference between homo- and hetero-polar mols. a deviation of about a 7% max. from the simple rule of mixts. should be expected. MARIE FARNSWORTH

A study of crystal structure and its applications. T. A. WILSON. *Gen. Elec. Rev.* 31, 612-21(1928).—An exhaustive review. C. G. F.

Space lattice analysis of potassium sulfate and potassium selenate. ELSA KOCH-HOLM AND NICHOLAS SCHÖNFELDT. *Wiss. Veröffentlich. Siemens-Konz.* 6, 177-87(1927).— K_2SO_4 and K_2SeO_4 are isomorphous with K_2CrO_4 (*Wiss. Veröffentlich. Siemens-Konz.* 5, No. 1). The space group is probably B_2^{13} . The unit cell contains 4 mols. The axial lengths, in A. U., are: K_2SO_4 — $a = 7.50$, $b = 10.25$, $c = 5.28$; K_2SeO_4 — $a = 7.60$, $b = 10.40$, $c = 6.02$; K_2CrO_4 — $a = 7.45$, $b = 10.30$, $c = 5.88$. BENJAMIN MILLER

Properties of large iron crystals. J. SEIGLE. *Tech. moderne* 20, 665-70(1928); cf. *C. A.* 21, 356, 2203.—The line of demarcation of the different crystals is visible with the naked eye although it remains a very thin line even under strong magnification. A rod, the cross section of which is formed of single crystals, does not possess an elastic limit. Permanent deformation is produced from the beginning; the resistance to traction is reduced by more than half. The striction is different from that in a rod made of normal crystals. Under torsion the elastic limit has also disappeared, the resistance to rupture is decreased and the rod is deformed along its axis. Fe made of large crystals is very sensitive to shock after a few minutes' immersion in liquid air but at normal temp. it is not thus sensitive and is also very ductile. In rupture by torsion, traction or shock, the line of rupture is never between two crystals but through one of them. Slip-bands and Neumann's lines are easily formed. Hardening by exposure to NH_3 fumes at 600° forms shorter lines than in fine crystal steel.

P. THOMASSET

Crystallographic orientation of metallic precipitates. G. TAMMANN AND M. STRAUMANIS. Univ. of Göttingen. *Z. anorg. allgem. Chem.* 175, 131-40(1928).—When Cu is electrolytically deposited upon Cu surfaces, the crystallite orientation of the deposit depends upon the character of the surface. On a polished surface the deposit is very fine and its orientation bears no relation to that of the cathode. If the surface of the cathode has been previously etched, the crystallite orientation of the deposit is identical with that of the electrode, if the c. d. is not too high. A satisfactory c. d. is 5-10 milliamp./sq. cm. with satd. CuSO_4 soln. as electrolyte. At high c. d. (above 30 milliamp./sq. cm.) the deposit tends to form new crystn. centers and as a result its orientation bears no relation to that of the cathode. If the metal is deposited from complex-salt solns., the formation of new crystn. centers is also favored. When Ni is deposited upon Cu from a NiSO_4 soln., the deposit at first follows the Cu in orientation, but this is only true for a very thin layer, after which the Ni is deposited in very fine crystals with irregular orientation. Cu deposited upon Ni at 2 milliamp./sq. cm. takes the Ni orientation. When Cu is deposited upon a single crystal ball of Cu, upon the surface of which all possible crystal planes are found, the deposit favors the plane with densest packing, the octahedral plane, the altitudes of the octahedra being arranged parallel to the lines of current flow.

H. STORITZ

Light figures of copper and iron. G. TAMMANN AND A. A. BOTSCHWAR. Univ. of Göttingen. *Z. anorg. allgem. Chem.* 175, 121-30(1928).—If a beam of parallel light falls upon an etched metal surface, it is reflected in the form of a definite figure, depending upon the crystallite orientation. The reflected light figure can be picked up on light-sensitive paper and studied. Cu is etched with 20% $(\text{NH}_4)_2\text{S}_2\text{O}_8$, Fe with 10% $(\text{NH}_4)_2\text{S}_2\text{O}_8$. With Al and Ag satisfactory etch figures are not obtained. If the light rays strike the crystallite planes at an angle, the figure obtained is different from that produced when the incident ray is perpendicular. An incident ray perpendicular to an octahedral plane gives a light figure with 3 equal branches with an angle of 120° between them. If the crystallite planes in question belong to the octahedral group, their angle of inclination with respect to the octahedral plane can be detd. by measuring the angle through which the incident ray must be moved to give a figure with 3 equal branches. The light figures obtained from a ball consisting of a single crystal of Cu are studied. This method is much more time-consuming than the detn. of crystallite orientation by the method of max. reflection, but the detn. of the angle of inclination of the various planes is an advantage.

H. STORITZ

The structure of crystalline carbons. ELSA KOCH-HOLM. *Wiss. Veröffentlich. Siemens-Konz.* 6, 188-201(1927).—A series of cryst. carbons was prepd. by the decompn. of hydrocarbons at temps. of 1200 – 2700° . Anthracite coal and retort carbon (made at 900 – 1000°) were taken as the first two members of the series. X-ray analysis showed the graphite space lattice in every case. The particle size increased with the temp. of formation, particularly the length in the 111 direction. The hardness increased to a max. at a 111 length of 90 A. U., corresponding to about 1300° , and then decreased. Porcelain is attacked by carbon and hydrocarbons above 1400° with the formation of aluminum carbide, which was detected by x-ray analysis.

BENJAMIN MILLER

Electric dipole moments of organic molecules. J. ESTERMANN. *Physik. Inst. Hamburg. Z. physik. Chem. Aht. B*, 1, 139-60(1928).—Dil. benzene solns. of three groups of substances, various ethers, compds. contg. two sepd. phenyl rings, and org. compds. contg. both strongly electropositive and electronegative constituents, chiefly esters of amino acids, have been investigated and the variation of their dielec. consts. with temp. have been detd. From these measurements are calcd. the dipole moments. E. discusses the relationship of elec. dipole moments and chem. structure, and also considers in some detail the sources of errors of such measurements, such as the diffi-

culties involved in the behavior of the solvents and errors thereunto attributable. Much exptl. detail, data and sketches are given. **WILLIAM E. VAUGHN**

Molecular light-scattering, dielectric constants and dispersion of several organic compounds. WERNER LAUTSCH. Physik. Inst., Königsberg. *Z. physik. Chem. Abt. B*, 1, 115-33(1928).—The degree of depolarization of 15 compds. in the liquid state is detd. They are acetophenone, benzophenone, *p*-methoxybenzophenone, propylbenzene, biphenyl, bibenzyl, triphenylmethane, naphthalene, decalin, ethyl stearate, ethyl palmitate, ethyl laurate, ethyl oleate, stearic acid and palmitic acid. There exists a parallelism between degree of depolarization and chem. constitution. The changes in dielec. const. with temp. for nine of the substances were measured. The work offers some confirmation to the dipole theory of Debye. Many detailed data are given.

WILLIAM E. VAUGHN

The electrical symmetry of the molecular structure of methane derivatives. L. EBERT, R. EISENSCHITZ AND H. v. HARTEL. Kaiser Wilhelm Inst., Berlin. *Z. physik. Chem. Abt. B*, 1, 94-114(1928).—The methods for the detn. of symmetry of mols. are discussed. The mol. polarization of many compds. of type Ca_4 in dil. soln. in C_6H_6 or CCl_4 have been detd. by use of 2.4-m. waves, and are found to behave as derivs. of three substances, $C(OH)_4$, $C(CH_2OH)_4$, or $C(COOH)_4$. Comparisons with mol. polarization of the same substances in the solid state tend toward the conclusion that a no. of these compds. have definite dipole moments. This decision supports the theory of Weissenbert, according to which there exists a multiplicity of structures of the mol. Ca_4 , as is illustrated by the models of classical stereochemistry.

WILLIAM E. VAUGHN

Determination of electrical dipole moments of organic molecules by the molecular beam method. J. ESTERMANN. Physik. Inst., Hamburg. *Z. physik. Chem. Abt. B*, 1, 161-9(1928).—Mol. beams of biphenyl, diphenylmethane, benzophenone, diphenyl ether and the methyl esters of *o*, *m*- and *p*-aminobenzoic acids were deflected in a non-homogeneous elec. field, and the dipole moments were detd. A detailed description of the app. and technic are given. The values obtained for the dipole moments are in accord with those obtained from dielec.-const. measurements.

W. E. V.

Relation between dipole moment and constitution. J. ERRERA. *Physik. Z.* 29, 689-90(1928).—E. had previously verified Debye's theory of permanent dipoles for the dihalo derivatives of C_2H_4 and C_6H_6 by showing that if the sign of the charges of the atoms of a mol. be known, the position of the atoms within the mol. can be detd. Hence chem. arguments which support assumed constitutional formulas can be directly verified. Van de Walle and Henne have established the position of the atoms in both stereoisomeric chloriodoethylenes (c. i. e.), $ClHC = CHI$, by chem. methods and E. now desires to investigate the reverse problem, *viz.*: Given the configuration, to det. the sign of the charge of some of the constituent atoms. Several chemists have already established the existence of derivs. of c. i. e. in which I is tervalent. For example, when c. i. e. is treated with Cl with simultaneous cooling, a cryst. compd. $ClHC : CHI Cl_2$ is obtained. If I is positively charged relatively to Cl then it follows that the *cis* deriv. in which both halogen atoms are nearest must have a smaller dipole moment than the *trans* deriv. Both *cis* and *trans* c. i. e. configurations have been detd. by the work of W., which is based on the existence of azeotropic mixts. with $PrOH$. E. finds that in the above compds. the hypothesis that I is relatively positively charged to Cl is established because the dipole moment of the *trans* is more than twice that of the *cis* deriv.

S. L. B. E.

The heat conductance of gas mixtures. H. GRUSS AND H. SCHMICK. *Wiss. Veröffentlich. Siemens-Konz.* 7, 202-24(1928).—The heat conductance of gas mixts. shows astonishing deviations from the simple law of mixts. In many cases there is a linear relation between the partial pressure of one of the gases of a binary mixt. and the conductance, while in other gases the mixt. may have higher conductance than either pure gas. The abs. values of the heat conductances of mixts. of air with H_2O , NH_3 and C_2H_2 , and of CO with NH_3 have been detd. at atm. pressure and at temps. between 20° and 80°. Improved app. and methods are described. The results, which are given in tables and graphs, show max. conductances for certain ratios. The departure from the simple law of mixts. is said to be due to the lowered attractive forces caused by the meeting of mols. having diff. orders of symmetry. This leads to fewer impacts, longer mean free paths and consequently higher thermal conductance.

BENJAMIN MILLER

Gas computation chart. FRITZ SCHUSTER. *Gas u. Wasserfach* 71, 1070-1(1928).—A chart gives factors for converting volumes of dry or saturated gas measured at 700-800 mm. Hg and at 0-30° to 0° and 760 mm. pressure, dry.

R. W. R.

Highly dilute flames. I. General. H. BEUTLER AND M. POLANYI. Kaiser Wilhelm Inst. *Z. physik. Chem. Abt. B*, 1, 3 20(1928); cf. *C. A.* 22, 1898.—The interaction of alkali metal vapors with halogens and certain halogen compds. at low pressure (10^{-6} mm.)

is accompanied by a non-thermal emission of the resonance line of the metal. The procedure is to allow the reactants to diffuse from opposite ends of a long tube and to investigate the distribution of d. in the pptn. formed in the region of reaction along with the distribution of intensity of the luminescence. Full details are given of the calcn. of the reaction velocity from an analysis of the pptn. curve. As the max. of the luminescence curve is always displaced toward the side of the entering alkali vapor with respect to the pptn. curve, the conclusion is drawn that the primary reaction, $\text{Cl}_2 + \text{Na} = \text{NaCl} + \text{Cl}$, is not the cause of the luminescence; it must originate in secondary reactions between some of the halogen atoms liberated in the primary reaction and the oncoming alkali vapor. The salt mol. resulting carries over its energy of formation to a Na atom in a collision of the 2nd kind. On the basis of this mechanism, the max. light yield is 0.03 to 0.5% of this value. With respect to the primary reaction it is shown that every collision is effective, with a collision area 10 times greater than the gas kinetic value. II. "Jet flames." ST. V. BOGANDY AND M. POLANYI. *Ibid* 21-9.—The light yield is much increased when the halogen is introduced through a jet into an excess of Na vapor. The influence of the alkali vapor concn. on the intensity of the luminescence was studied. For the reaction between Cl_2 and Na, the yield increased approx. linearly from 1% of theoretical at a Na pressure of 0.5×10^{-3} to 35% at 10^{-2} mm. The curve showed a tendency to bend over toward the pressure axis at higher pressures. The behavior with Br_2 was similar but with HgCl_2 the luminescence curve rapidly reached a limiting value of 7% of the theoretical, beyond which increase of the Na concn. caused no further increase in intensity of luminescence. III. The sodium-chlorine flame. M. POLANYI AND G. SCHAY. *Ibid* 30-61.—The flame reactions belong to two classes, with the following empirical characteristics: Class I (Na or K with Cl_2 , Br_2 , I_2 , ClCN , BrCN). (a) The luminescence curve of the jet flame is much broader than the pptn. curve. (b) Increase in temp. of the reaction zone diminishes the luminescence. (c) The light yield increases with Na concn. more rapidly than the concn. (d) If the reaction between Na and Cl_2 is performed in the presence of H_2 , HCl is formed. Class II (Na or K with HgCl_2 , HgBr_2 , SO_2Cl_2). (a) Luminescence curve of the jet flame coincides with the pptn. curve. (b) Increase in temp. of reaction zone does not affect brightness of luminescence. (c) The light yield increases with Na concn. more slowly than the concn. (d) In presence of H_2 , no HCl is formed in the reaction between Na and HgCl_2 . The following mechanisms account for the observed facts. Type I. (1) Primary reaction, in gas phase without luminescence, $\text{Na} + \text{Cl}_2 = \text{NaCl} + \text{Cl} + 35 \text{ Cal.}$ (2) Secondary reactions (a) $\text{Na} + \text{Cl} = \text{NaCl}$, at wall, without luminescence. (b) $\text{Na}_2 + \text{Cl} = \text{NaCl} + \text{Na} + 75 \text{ Cal.}$ (about) in gas phase. The light is produced by reaction (b), in the collision of an energy-rich NaCl mol. with a Na atom which has not participated in the reaction. Type II. Primary reaction $\text{Na} + \text{HgCl}_2 = \text{NaCl} + \text{HgCl} + 25 \text{ Cal.}$ Secondary, $\text{Na} + \text{HgCl} = \text{NaCl} + \text{Hg} + 53 \text{ Cal.}$ The energy-rich NaCl mol. excites a Na atom as before. The essential difference between the 2 types is that the first requires the production of free halogen atoms and the presence of diatomic Na_2 mols., while the second requires neither. The intensity of luminescence of the $\text{Na} + \text{Cl}_2$ flame falls off exponentially with increasing temp. and leads to a value of the heat of dissocn. of Na_2 mols. of 18 Cal. ± 2 . (Cf. Loomis' spectroscopic value of $23 \pm 2.3 \text{ Cal.}$) A calcn. is made which shows that in the flame reactions, the reaction between free atoms and mols. as $\text{Na} + \text{Cl}_2 \rightarrow \text{NaCl} + \text{Cl}$, takes place at every collision, and in fact with a collision area greater than the gas-kinetic, while the fraction of collisions between Na and Cl atoms in the gas space which lead to formation of a NaCl mol. is not more than 1/10,000. IV. The sodium-iodine flame. H. OOTUKA AND G. SCHAY. *Ibid* 62-7.—A detailed investigation of the Na I flame, with results in accordance with the hypotheses advanced above. V. The sodium-mercuric chloride flame. *Ibid* 68-73. Wm. West

The equation of state of a mixture determined from the equations of state of its constituents, and its application in determining the physical and chemical properties of a mixture in terms of those of the constituents. R. D. KLEEMAN. *J. Franklin Inst.* 206, 511-24 (1928).—The equation of state of a mixt. may be expressed in its general form by $p = \psi(T, v, M_a, M_b, \dots)$. From this the equation $p = \psi((A_1 M_a + B_1 M_b + \dots)/v, (A_2 M_a + B_2 M_b + \dots)/v, \dots)$ is derived, which directly leads to the equations of state of the constituents e. g., $p_a = \psi(A_1(M_a/v), A_2(M_a/v), \dots)$, $p_b = \psi(B_1(M_b/v), B_2(M_b/v), \dots)$, etc. This general formulation can be combined with van der Waals' equation of state. The nature of the phases into which a mixt. seps. can be detd. from the equation of state of the mixt. Other applications of this principle are the detn. of the equation of state of an interacting gaseous mixt. from the equations of state of the constituents, the detn. of the sp. heat of the internal energy and the magnetic and elec. energies of the mixt. at infinite vol. from the energies of the iso-

lated constituents. It should also be possible to express the properties of complex compds. in terms of the same properties of the constituents, *e. g.*, the phys. properties of HCl in terms of those of H₂ and Cl₂. The subject is to be amplified in a subsequent paper.

EMIL KLARMANN

Gaseous mixtures. NELLO CARRARA. *Nuovo cimento* [N. S.] 5, 224-33(1928).—A math. interpretation of the final conditions which would be established in a mixt. of several gases that could not react together chemically. The final conditions of the mixt. were compared with that corresponding to the equation characteristic for a perfect gas.

L. T. FAIRHALL

The specific heat of carbon dioxide. A correction. W. H. MCCREA. *Proc. Cambridge Phil. Soc.* 24, 290(1928); cf. *C. A.* 22, 718.—In his previous paper, McC. suggested the possibility of a transition from one mol. form to another in CO₂. The suggestion was embodied in an equation and the resulting sp. heats for low temps. were given. Now it has been found that this assumption gives a high and altogether impossible max. in the sp.-heat curve for higher temps. before it returns to the neighborhood of the unmodified curve C_p. The effect of assuming a difference of potential energy between the two positions about which the system is considered to vibrate has been tried. A curve was obtained for a value of this energy difference corresponding to a frequency ν_2 , and a fundamental frequency $2\nu_2$ (to give bands ν_2 , $3\nu_2$. . . since Schaefer and Philipps did not find $2\nu_2$), and a moment of inertia 0.5×10^{-40} g./sq. cm. While this curve agrees with observation for low temps. and almost coincides with C_p for high temps. and does give a max. in between, there is still a good deal of discrepancy there. Though the question is not yet cleared up, McC. still holds that a triangular form of the mol. with some anomalous behavior at low temps. is demanded by the facts.

A. L. HENNE

The decomposition pressure of sulfuric acid containing nitro compounds. A. SANFOURCHE AND L. RONDIER. *Bull. soc. chim.* 43, 815-26(1928).—The importance of thorough knowledge of the equil. reactions involved in the chamber process for H₂SO₄ led S. and R. to extend the work of Sorel. The pressures developed by HNO₂, HNO₃, and HNO₂-HNO₃ mixts. in H₂SO₄ of the usual chamber strengths were detd. by a dynamic method, colorimetric analyses being used. Tables are given showing that the decompn. pressure of nitrosylsulfuric acid increases with increase in nitrous content, with increase in temp., and with decrease in H₂SO₄ concn., that the decompn. pressure of nitric-sulfuric acids increases with decreasing concn., passing through a max. about 60° Bé. and then decreasing as diln. continues; that small amts. of HNO₃ in nitrosylsulfuric acid increase the pressure of the latter disproportionately, the increase being more marked as the H₂SO₄ becomes more concd. The effect of HNO₃ on the pressure of SO₂-(OH)(ONO) is due to the formation of N₂O₄.

C. H. PEET

The intensive drying of liquids. SAM LENHER AND FARRINGTON DANIELS. Univ. of Wisconsin. *Proc. Nat. Acad. Sci.* 14, 606-9(1928).—Tubes contg. P₂O₅ and org. liquids were sealed. It was proposed to keep them at room temp. for 9 yrs. and then to det. the b. p., mol. wt., surface tension, refractive index, etc., of the dried liquids. At the end of 4.5 years 3 of the tubes were opened and the B. ps. detd. in a modified Mathews app. (cf. *C. A.* 5, 3529). Two samples of dried C₆H₆ and 1 of CCl₄ showed no abnormal rise in b. p.

R. L. DONGE

The thermal coefficient of expansion of binary mixtures. K. M. STAKHORSEKII. *Ukrainskii Khim. Zhurnal* 3, No. 2, Pt. sci. 219-22(1928).—S. derives an equation for the thermal coeff. of expansion, α , of binary mixts. of the non-assocd. liquids $\alpha = (M_1v_1\alpha_1X + M_2v_2\alpha_2(1-x))/(M_1v_1X + M_2v_2(1-x))$ where M_1v_1 and M_2v_2 are the molar vols. of the pure components, α_1 and α_2 their coeffs. of expansion and x is the molar fraction of the first component of the mixt. This equation is compared with some known data on mixts. of CCl₄ and C₆H₆, CCl₄ and PhCl, CCl₄ and PhBr, C₆H₆ and PhMe, C₆H₁₄ and Et butyrate, PhEt and EtOAc. Fairly good agreement is obtained.

G. B. KISTIAKOWSKY

Osmosis of liquids. General considerations. F. A. SCHREINEMAKERS. Univ. Leiden. *J. Gen. Physiol.* 11, 701-13(1928); cf. Schreinemakers (*C. A.* 19, 1805; 22, 1713).—Ternary liquids may be represented as consisting of substances X, Y and W. If 1 g. of this liquid contains x g. of X, and y g. of Y, it will then contain $(1-x-y)$ g. of W and its compn. is represented by s g. X + y g. Y + $(1-x-y)$ g. W. The compn. of this liquid may also be represented by a right angle triangle, X, Y, W (Fig.), in which $WX = WY = 1$. $Wb = x$ and $Wa = y$. The point q then represents X and Y quantities of the liquid and $qa = x$ and $qb = y$. From the Fig. $qb = Wa$ and $qa + qc = ac = aY$. As $Wa + aY = 1$, we have: $qa + qb = qc = 1$, or $x + y + qc = 1$. $qc = 1 - x - y$, or $qc =$ the W amt. of the liquid. Consequently the point q represents a liquid which

contains $qa = x$ quantities of X, $qb = y$ quantities of Y and $qc = (1 - x - y)$ quantities of W. If q is on WX then $y = 0$ and the liquid contains only W and X; if q is on WY then $x = 0$ and the liquid contains only W and Y; if q is on XY then $(1 - x - y) = 0$ and the liquid contains only X and Y. If q coincides with angular point W then $x = 0$, $y = 0$ and $(1 - x - y) = 1$, the liquid consisting of W only. Also point X represents pure X, and point Y pure Y. Therefore the angular points of the triangle represent the 3 pure substances W, X and Y, the sides the binary liquids contg. either W + X, W + Y or X + Y, and the points within the triangle ternary liquids contg. X + Y + W. Similarly, the relations are developed for an osmotic system in which two liquids are sep'd. by a membrane permeable only for W. W diffuses in one of two directions or does not diffuse at all; in the latter case the liquids are isotonic. Certain points within the triangle may be connected by lines to form isotonic curves, having the following properties: (1) Two isotonic curves never intersect or touch one another; (2) every straight line passing through W intersects a curve in one point only; (3) the osmotic water attraction of the liquids of an isotonic curve is greater the farther this curve lies from W; (4) the isotonic curves are straight lines in the vicinity of W, but are curved at greater distances. The many cases which may occur with the osmosis of one or more substances are shown by a system of signs. Positive and negative osmosis are pictured in this way

C. H. RICHARDSON

Effect of molecular form and association on light-scattering in liquids. I. Fatty acids and alcohols. S. RAMACHANDRA RAO. Sri Minakshi College, Chidambaram. *Indian J. Physics* 3, 1-19(1928).—The variations of intensity and depolarization factor of the transversely scattered light have been studied for MeOH, EtOH, PrOH, BuOH, AcOH, EtCO₂H and PrCO₂H. Graphs show the changes in the values of the depolarization factor with temp. A regular gradation, in shape is noticeable for the alcohols, in ascending the series, MeOH behaving in the usual manner. AcOH shows a rapid fall up to 120° and then a gradual diminution. EtCO₂H and PrCO₂H show an initial fall in the value of r , then a horizontal part and at higher temps., a steady fall. On the basis of Ramanathan's recent expression for the intensity of the transversely scattered light (C. A. 22, 3782) the intensities at different temps., compared to that at 30° in the case of EtOH and to that at 120° in the case of AcOH, have been calcd. It is found that the calcd. and observed values show a closer agreement in the case of EtOH than in the case of AcOH. On drawing curves between Δ , the optical anisotropy, and temp. it is noticed that MeOH shows a high value at ordinary temps., the rise becoming very slow at high temps. The higher alcohols show almost steady values at ordinary temp. The fatty acids behave very peculiarly. AcOH shows a rapid fall in the value of Δ at first, and then a gradual rise. EtCO₂H and PrCO₂H show an initial rise and fall in the value of Δ and later a gradual rise. **II. Some aromatics.** *Ibid* 21-30.—The depolarization factor and intensity of the transversely scattered light and the optical mol. anisotropy have been det'd. for 4 typical polar aromatic compds.: PhNO₂, PhNH₂, PhEt and PhBr. The calcd. and observed values of the intensity of the transversely scattered light at different temps., if that at 30° is unity, do not agree, the difference becoming smaller at higher temps. This was found to be the case with PhNO₂ predominantly and to a small measure with PhNH₂. In the cases of PhNO₂ and PhNH₂, again, the value of the optical anisotropy diminished as the liquids were heated up to a certain temp. and then rose with increase of temp. This behavior as well as the anomaly in the case of intensity are suggested to be due to mol. assocn.

G. CALINGAERT

Volatility with steam of water-soluble organic substances. ARTTURI I. VIRTANEN AND L. PULKKI. *J. Am. Chem. Soc.* 50, 3138-51(1928).—See C. A. 22, 4351. E. H.

The vapor pressures of the heptahydrate and the saturated solution of sodium sulfite. KIMIO ARII. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 891-904, Eng. Ed. 1, 83-4(1928).—The vapor pressure of the systems: (a) Na₂SO₃·7H₂O-Na₂SO₃; (b) Na₂SO₃·7H₂O-satd. soln.; (c) Na₂SO₃-satd. soln., were measured at various temps. by means of the static method; a modified Bremer-Frowein differential tensimeter was used: the values were: (a) (temp. in °C., pressure in mm. Hg): 15, 8.76; 20, 12.99; 25, 18.59; 30, 26.33; 33, 32.78; (b): 20, 16.24; 25, 21.61; 30, 28.38; 33, 32.99; (c): 35, 37.01; 40, 48.88; 45, 63.74; 50, 82.39. These values agree with those calcd. by means of the following equation: (a): $\log p = 10.65647 - 2797.12/T$; (b): $\log P = 8.50733 - 2138.23/T$; (c): $\log p = 9.04857 - 2304.20/T$. At the transition point between the heptahydrate and the anhydride, the vapor tensions of the 3 systems should be the same and the 3 vapor-pressure curves should intersect. The transition point was actually found at 33.6°, while it was calcd. at 33.49° by solving pairs of the above equations and

taking the av. Recent results obtained by Tarassenkows (*C. A.* 22, 1890), are criticized and held as erroneous.

A. L. HENNE

The vapor pressure of water over sulfuric acid-water mixtures at 25°, and its measurement by an improved dew-point apparatus. J. R. I. HEPBURN. *Proc. Phys. Soc. (London)* 40, 249-50 (1928).—A modified method of compilation has been adopted in this paper, by means of which a series of most probable values for the vapor pressure of water over sulfuric acid-water mixts. at 25° has been obtained. An improved dew-point app. was used, with the methods originated by Lescoeur and improved by Cummings. An examn. of data previously used by Wilson showed that serious divergencies exist in the results of the investigators from which his data were drawn. F. V. J. JR.

The reaction velocity between trichloroacetic acid and amylene in different solvents. L. M. ANDREASOV. *Ukrainskii Khim. Zhurnal* 3, No. 2, Pt. sci. 209-18 (1928).—A. describes preliminary measurements of the rate of reaction of amylene and $\text{CCl}_3\text{CO}_2\text{H}$ at 25° in 5 different solvents: C_6H_6 , $\text{C}_6\text{H}_5\text{NO}_2$, CHCl_3 , CS_2 and CCl_4 . The reaction rate decreases in the order of the solvents given above. The velocity consts., calcd. for a bimol. reaction, decrease with progress of reaction, indicating the presence of some secondary processes.

G. B. KISTIAKOWSKY

Catalytic acceleration of the oxidation-reduction of formic acid-methylene blue. J. V. EULER AND ARNE ÖLANDER. *Z. physik. Chem. Abt. A*, 137, 29-44 (1928).—With Bredig's Pt-sol the max. reaction velocity was found at p_{H} 2-3. The reaction velocity is detd. by the existence of a mol. species HCOOH-Pt catalyst, the concn. of which varies with p_{H} . A certain threshold value of the Pt-sol concn. is necessary as the methylene blue consumes a certain quantity of catalytically effective Pt compd. With rising methylene blue concn. velocity of decolorization diminishes. Only mol. HCOOH participates in the formation of the intermediate active mols. A. P. SACHS

Catalysis of reactions of solids by solids. S. ROGINSKII AND E. SHULTZ. *Ukrainskii Khim. Zhurnal* 3, No. 2 Pt. sci. 177-207 (1928).—In continuation of some earlier expts. (cf. *C. A.* 21, 2415) R. and S. have studied the rates of decompn. of KMnO_4 and of $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$ and the effect on these of several powdered oxides. The rate of evolution of O in decompn. of KMnO_4 was found to show a period of induction and to be autocatalytically accelerated. Similar results were obtained with crystals and with the finely powdered substance, although the latter decomposes much faster. The products of decompn. (K_2MnO_4 , K_2MnO_3 and MnO_2) accelerate the decompn. Present in large quantities, they change the character of the reaction, no autocatalysis or induction being observed. Similar results were obtained with $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$. R. and S. reject the theory of the reaction mechanism postulated by Hinshelwood and Bowen (cf. *C. A.* 15, 618) and suggest that the decompn. starts at definite reaction centers on the surface and spreads throughout the crystal. They distinguish two phases of the reaction: the initial stage of the increasing velocity when the reaction zones are small and can grow unhampered in all directions in the crystal and the final stage of decreasing velocity when the whole surface layer of the crystal is decomposed and the reaction can progress towards the center only. For both cases they derive kinetic equations which agree well with their exptl. data. They apply the equations to the exptl. results of Tzentnershver and Bruzs (cf. *C. A.* 20, 3623) and of Tzentnershver and Awerbuch (cf. *C. A.* 20, 3623) on the rates of thermal dissocn. of carbonates of Cd and Pb, obtaining also good agreement. A no. of powdered oxides have been tried for their effect on the rate of decompn. of KMnO_4 . The following were found to be active catalysts: NiO , MnO_2 , CuO , Fe_2O_3 , Co_3O_4 . Their activity depends on the mode of prepn. and can be destroyed by superheating. Promoter action has also been observed in case of Al_2O_3 , which itself is only a poor catalyst but when added to Fe_2O_3 increases the latter's activity very markedly. The effect of catalysts is more pronounced with powd. KMnO_4 than with the cryst. substance. It has been found that when KMnO_4 is rapidly heated to temps. at which the decompn. is fast, in absence of catalysts, the latter act retardingly on the rate. R. and S. call the effect "inversed catalysis" and interpret it in terms of the superheating of the reacting substance due to the heat evolved in the decompn. and of the influence of admixed foreign substances on such superheating. G. B. KISTIAKOWSKY

Autoxidation and antioxygen action. XXX. The autoxidation and polymerization of chloral: the action of light. CHARLES MOUREU, CHARLES DUFRASSE AND GERARD BERCHET. *College de France, Paris. Bull. soc. chim.* 43, 942-57 (1928).—The oxidation of CCl_3CHO (I), is studied. I is purified by converting it to metachloral (II), with the aid of 5-6 pts. H_2SO_4 . II is repeatedly washed, dried *in vacuo* and converted to I by heating to 180-200°. The hydrate of I, m. 57°, was prepd. by the addn. of the calcd. distd. H_2O . The oxidation of I is given as: $\text{CCl}_3\text{CHO} + \text{O}_2 \rightarrow \text{HCl} + \text{CO}_2 + \text{COCl}_2$. The calcd. amt. of O_2 is added to I and the mixt. is allowed to stand 30 days.

A marked increase in pressure is noted after 8-10 days. In every oxidation HCl , CO_2 , COCl_2 , $\text{CCl}_2\text{CO}_2\text{H}$ and Cl_2 are liberated. In sunlight, more than the calcd. HCl and CO_2 are obtained but only 24% of the calcd. COCl_2 . In electric light there is polymerization and much less than the calcd. amt. of gas formed. Pure I in the dark with O_2 showed no oxidation after 83 days. However, I heated in the light forms a product which catalyzes its interaction with O_2 in the dark. The hydrate of I does not appear to be autoxidizable, but if dehydration occurs through the formation of HCl , it will proceed. Exptly., there was induction of 52 days before the formation of I and its oxidation. There appears to be disocn. of $\text{I} \rightleftharpoons \text{CCl}_2 + \text{HCICO}$ or of the type $\text{I} \rightleftharpoons \text{CCl}_2\text{CO} + \text{HCl}$. The idea of a preliminary disocn. is strengthened by the observation of a spontaneous production of gas in I without any oxidation. XXXI. The action of different catalysts. *Ibid* 957-62.—It has been possible to protect I against autoxidation by the addn. of 0.1 to 1.0% antioxygen for the period studied up to 100 days. The following compds. decreased the rate of oxidation very greatly when 0.1% was used: hydroquinone, pyrocatechol, α -naphthol, β -naphthol, pyrogallol, resorcinol, phloroglucinol, hydroxyhydroquinone and gallic acid. 1% PhOH gave similar protection. Complete protection is given by 0.1% PhNH_2 , p - $\text{ONC}_6\text{H}_4\text{NMe}_2$, Ph_2NH or α -naphthylamine and distn. after 3 yrs. showed no evidence of polymerization. H_2NCSSEt was found to have no effect, while S and I_2 were fair and PhNHMe III afforded complete protection. D. H. P.

Oxidation of hexane. MAX BRUNNER. *Techn. Hochschule, Zürich. Helv. Chim. Acta* 11, 881-97(1928); cf. *C. A.* 22, 3130.—The slow oxidation at 210° of a gas mixt. contg. 42% C_6H_{14} , 57% O and 1% N was studied, the vol. and temp. being kept const. At first the reaction proceeds with only a slight change in the pressure, although the reaction velocities are high, as shown by analyses of the reaction products at different states. Later there is an increase in the pressure, which is smaller, less sudden and less rapid if the glass surface has been increased, e. g., by the addn. of powd. Pyrex or quartz glass. During the reaction, moloxides (*i. e.*, unstable intermediate oxidation products) and peroxides are probably formed first; they then undergo secondary reactions, resulting in the formation of H_2O , unsatd. compds., fatty acids, CO_2 , CO and other gases. Quant. investigations of the reaction products show that in addn. to the (assumed) formation of moloxides and of peroxides, the manner of oxidation of H atoms is of importance. The unsatd. intermediate products thus formed will take up O, forming new (secondary) peroxides. The decompn. and reaction of both primary and secondary peroxides results in a series of further changes, which may lead to the formation of aldehydes, peracids and other products. Soon after the peroxides have reached their max., no more free O is present; a further formation of moloxides, peroxides, H_2O and fatty acids cannot occur, but the decompn. of the peroxides present into CO_2 , CO and other gases continues. It is this decompn. which causes the marked increase in pressure toward the end of the reaction.

LOUISE KELLEY

Unilateral and non-unilateral reaching of equilibrium in the literature. EMIL BAUR. *Z. physik. Chem. Abt. A*, 137, 63-71(1928).—In certain cases of inversion or transformation a true equil. exists, but it can be reached only from one side as the reaction const., contrary to Guldberg's classical law, is not the same in both directions. This conception of unilateral equil. differs from Duhem's principle of false equil. which postulated relatively reactionless zones near the equil. point while maintaining the principle of equal velocities at equal distances from the equil. point. B. gives as examples the isomerization of BuBr , the transformation of hexachloro- α -keto- β -R-pentene into hexachloro- α -keto- γ -R-pentene, and the isomerization of the tolane dibromides. A. P. S.

A theory of partial osmotic pressures and membrane equilibria, with special reference to the application of Dalton's law to hemoglobin solutions in the presence of salts. G. S. ADAIR. *Proc. Roy. Soc. (London)* A 120, 573-603(1928).—The osmotic pressures of hemoglobin solns. in equil. with solns. of diffusible salts have been measured and correlated with detns. of the membrane potentials, and the distribution of diffusible ions. Although the relationships between the activities of diffusible ions and the membrane potentials are in accordance with Donnan's theory, his assumptions concerning osmotic pressures are not applicable to the protein solns. of finite concn. which have been studied in this work. (Cf. F. Donnan, *C. A.* 6, 1559; F. Donnan and A. J. Allmand, *C. A.* 9, 171.) Within certain ranges of hydron, salt and protein concn., a modified form of Dalton's law of partial pressures appears to be applicable for the purpose of analyzing the observed osmotic pressures in terms of p_i , the diffusible ion pressure difference, and p_p , the partial osmotic pressure of the protein ions. Systematic exptl. investigations of the partial pressures indicated that certain variations formerly attributed to changes in aggregation are due to the existence of great deviations from the law of van't Hoff. In solns. with H-ion concns. from 10^{-4} to 10^{-9} , and with NaCl

concs. from 0.01 to 4 mols. per l., and in solns. with different species of ions, including K, Na, NH₄, Mg, Cl, HCO₃, SO₄, H₃PO₄, HPO₄, the degree of aggregation of hemoglobin appears to be const. Methods for detg. the mol. wt. of proteins in non-ideal solns. contg. salts have been developed. The value 67,000 obtained for hemoglobin in physiol. salt solns. agrees with that previously detd. for hemoglobin in distd. water. G. C.

The pore size of compressed carbon and silica membranes. F. E. BARTELL AND H. J. OSTERHOF. Univ. of Michigan. *J. Phys. Chem.* 32, 1553-71 (1928).—A discussion and extensive review is given of the literature referring to the methods for the detn. of capillary radius by means of (1) decrease in vapor pressure with increasing curvature of meniscus, (2) height of rise in a capillary and (3) application of Poiseuille's law to the rate of flow through a capillary. The pore sizes of compressed C and SiO₂ membranes are measured by capillary rise and by Poiseuille's formulations and a comparison made between the results obtained. With C membranes C₆H₆, McPh and CHCl₃ were used, since they have zero contact angles. Similarly with SiO₂, H₂O and C₆H₆ were used. The equation used is: $R = 2S/Pg$ where S = surface tension at 25°, P = the equil. pressure in g. per sq. cm. and g is 981 dynes per g. The values of the pore radius of C for the different solvents were 9.29, 9.26 and 9.36×10^{-6} cm., resp., and for SiO₂ were 210.6 and 210. Poiseuille's formulation is cor. for this study and used in the following condition: $R = \pi/2 \cdot l \cdot \sqrt{8\eta Q/PVgt}$, where l = interior length of the displacement cell, η is a const. in dyne secs. per cm., Q is the vol. in cc. of liquid forced through the cell, and V = total pore vol. The value for R obtained by this method is 8.83 for C and 168 for SiO₂. By extrapolating these values to zero time the values 9.23×10^{-6} cm.² and 205×10^{-6} cm.² are obtained, which are in astonishingly close agreement with the values given above. The C was packed under 2500 lb. pressure and the SiO₂ under 3000 lb. pressure. The no. of pores per sq. cm. of membrane surface was calcd. for C as 20.8×10^8 and for SiO₂ as 30.9×10^8 and it is clear that the mean effective pore radius decreases as the no. of pores in unit cross section increases. The velocity of the liquid through a C pore is given as 4.08×10^{-4} cm. per sec. D. H. POWERS

Studies in periodic precipitation. F. E. LLOYD AND V. MORAVEK. McGill Univ. *Plant Physiology* 3, 101-30 (1928).—The expts. were conducted in glass or vitreous tubes of various bores (15 mm.–0.5 mm.) and also in the capillary spaces between the glass slides and square cover-glasses used in microscopy. These were filled with "Gold label" or "Difco" gelatin contg. the "reacting material"—either Co Na hexanitrite or Co-(NO₂)₂·6H₂O. After the mixt. had set the "entering reagent," either (NH₄)₂S or NH₄OH, was added. The details of the technic adopted are given. Photographic records of all expts. made are recorded in the 74 figures accompanying the paper. The ppt. is laid down as fine or coarser granulations or droplets in a metastable condition. Because of the proximity of surfaces favoring local absorption of the ppt., these granulations become distinctly visible when there is a structural basis, such as minute tubercles, etc. Localization of ppt. is due to the role played by the surface of the inclosing vessel (the gelatin or water-glass-wall interface) whereby a ring-and-disk structure arises. In minute glass tubes, having a diam. greater than a certain crit. value, the ppt. occurs attached as a ring to the walls, without the disk. This crit. diam. is related to the rate of movement of the ions concerned, i. e., periodic pptn. does not depend for its occurrence on a capillary space, but its fixation depends on the presence of appropriate surfaces. Thus, in a wide enough tube, and in the case for example of Co(OH)₂ pptd. in gelatin, the ppt. is adsorbed on the glass wall as a ring, and within or upon the gelatin itself as a disk. In the absence of a glass (or other) wall only diffusion-shell patterns will arise. It is urged, however, that some surfaces ("nuclei") are further required. L. and M. consider that the evidence derived from their expts. support Bradford's ideas (*Sci. Progress* 10, 369, 1916) that the ppt. furnishes surfaces toward which the surrounding solute moves, adding to each particle more material. The more surfaces that are provided and the more irregular they are, the more diverse the patterns are which arise from periodic pptn. The heterogeneity of the medium, such as that which the living cell or body presents, furnishes conditions in which extreme irregularity of pattern would arise from periodic pptns. Biol. material should be examn. free from prejudice from the conditions producing "Liesegang rings." Differences of temp. affect the results in a large degree. Low temps. did not favor regularity, or even the obvious occurrence of periodic pptn. WALTER THOMAS

The alcosol of silicic acid. KENKYO INABA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 948-56; English Ed. 1, 92-3 (1928).—The alcosol of SiO₂ is easily prepd. from Si(OEt)₄ by hydrolyzing it with the calcd. amt. of H₂O in the presence of small quantities of HCl or H₂SO₄. To attain the best results Si(OEt)₄ is first dild. with EtOH to keep the acid concn. from exceeding 0.02-0.06 N. The mineral acid present in the alcosol is

removed either by means of a metallic oxide such as Ag_2O or PbO which is itself insol. in EtOH and forms a salt also insol. in EtOH , or by electrodialysis, with a parchment paper or collodion film as a diaphragm. The SiO_2 -alcosol thus prep'd. is a colorless, transparent, viscous liquid. The sp. cond. of an alcocol contg. 16–18% SiO_2 at 25° is $2.5\text{--}3.0 \times 10^{-5}$ and the sp. viscosity is 3–3.5 at the same temp. The stability of the alcocol is greater than that of the hydrosol. Sols contg. about 20% SiO_2 remain unaltered for 90 days; those at 10% keep over years. The relation $C = C_0/1 + \alpha T^n$ (where $C = \text{SiO}_2$ concn. T = time required for coagulation, $C_0 = C$ at a time $T = 0$, α and n = consts. depending on the nature of the sols) exists between the stability and the concn. Though the addn. of an electrolyte decreases the stability, the sensitivity of the alcocol toward electrolytes is only trifling. The influence of inorg. acids is greater than that of org. ones. The action of neutral substances is comparatively slight. Ethyl phosphate, camphor and naphthalene increase the stability of the sols. A. L. HENNE

Some further experiences with the production of colloidal lead or salts of lead. M. C. REINHARD, K. W. BUCKWALD AND K. L. TUCKER. *J. Cancer Research* 2, 160–5 (1928).—A method is described for the production of colloidal solns. of Pb and Pb salts, from Pb acetate in gelatin and 10% Na orthophosphate. The influence of pH and of the protective colloids was studied, and also the microscopic characters of such colloidal solns. H. G. WELLS

Colloidal solution of composite (high-molecular) compounds by means of substances which possess true solubility in abundance and which are inclined to a great solvation. P. P. V. VEIMARN. Imp. Univ. of Kyoto. *Japan. J. Chem.* 3, 71–87 (1928); cf. *C. A.* 21, 3514.—Ten g. casein was easily dispergated within 15 min. in 100 cc. of a concd. aq. soln. of pyrogallol (I) at 108° , and also, but more slowly, in a concd. aq. soln. of resorcinol (II) at $108\text{--}10^\circ$. Japanese silk (15 g.) was rapidly dispergated in 100 cc. of I at $115\text{--}25^\circ$, and in II at $135\text{--}40^\circ$. When cellulose in the form of very pure filter paper was heated with a concd. aq. soln. of I at $145\text{--}55^\circ$ (0.70 g. in 30 cc.) only a part of it was dispergated after 10–15 min. Aq. solns. of thiourea and guanidine thiocyanate also dispergate composite compds., e. g. silk. LOUISE KELLEY

Breaking up of emulsions by high-voltage alternating current. STEFAN PAWLKOWSKI. Lwow Polytech. *Przemysl Chem.* 12, 501–25 (1928).—The effect of outside influences on the stability of H_2SO_4 in crude-oil emulsions was studied. The emulsions were prep'd. according to a standardized elec. dispersion method and their breaking up was studied under the influence of a 50-cycle a. c. up to 17,000 volts. Cottrell's theory of the action of elec. forces dependent on potentials and dielec. consts. of the substances has been amplified and confirmed. A condition of rapid coagulation of an emulsion is inequality of the elec. field. Droplets of the dispersed liquid are drawn into places where the lines of elec. field are the densest and are there coagulated. Only in certain simplified cases was it possible to find the optimum conditions for deformation of the field whether by the application of slits or the use of holes of definitely varied diams. in the electrodes. Several types of app. used are described. The result of coagulation is a function of the potential employed; this phenomenon is explained by further proving that a secondary dispersion of the coagulated phase may take place at the electrodes on increasing the potential sufficiently. A. C. ZACHLIN

Rhythmic precipitation in gels. D. AVDALIAN. *Ukrainskii Khim. Zhurnal* 3, No. 2, Pt. sci. 223–30 (1928).—A. has studied the formation of Liesegang rings in gelatin caused by the reaction of $\text{K}_2\text{Cr}_2\text{O}_7$ and AgNO_3 . An addn. to the gel of indifferent electrolytes, as for instance KNO_3 , progressively diminishes the distance between the rings. The effect is interpreted on the basis of Ostwald's theory as due to a decrease of the metastable limit of the supersatd. solns. by added electrolytes. Phenomena occurring when AgNO_3 diffuses into a gelatin gel contg. $\text{K}_2\text{Cr}_2\text{O}_7$ and NaCl in varying concns. have also been studied. Various types of ppts. are interpreted as the combined effect of a continuous pptn. of AgCl and a rhythmic pptn. of $\text{Ag}_2\text{Cr}_2\text{O}_7$. G. B. KISTIAKOWSKY

The degree of dispersion in solutions of metals in fused salts (pyrosols). ERICH HEYMANN. *Z. anorg. allgem. Chem.* 175, 241–4 (1928).—Eitel and Lange have demonstrated experimentally (cf. *C. A.* 23, 16) that solns. of Pb in fused PbCl_2 or of Cd in fused CdCl_2 do not contain colloidal metal particles; the dispersion is rather a mol. one. By applying March's equation, which defines the conditions of stability of disperse systems (cf. *C. A.* 22, 3088), the mean diam. of a metal particle can be calcd. from the surface tension at the boundary of metal and salt. At 1000° abs. the mean diam. of a Pb particle is not more than 3×10^{-8} to 8×10^{-8} cm., i. e., the individual particle consists of a few atoms, possible of one atom only. For Cd a mean diam. of 10^{-7} to 3×10^{-7} is obtained. This would indicate that the Cd particle occurs in an extremely fine colloid subdivision comparable with that of the very finely dispersed amicrotic Au

particles. The latter finding, which also represents an upper limit of particle size, requires exptl. corroboration.

Solubilities of some inorganic fluorides in water at 25°. R. H. CARTER. *Ind. Eng. Chem.* 20, 1195(1928).—A comparison of the values given in the literature with those obtained by C. Literature references to solubilities are also given. C. H. PEET

Eutectic. DAVID W. HORN. *Am. J. Pharm.* 100, 558-61(1928).—A discussion and defense of the original definition of the scientific term *eutectic* as introduced by Frederick Guthrie (*Phil. Mag.* [5], 17, 426(1884)). W. G. GABSSLER

Enantiotropy and monotropy. II. NOBORU NAGASAKO. *Bull. Chem. Soc. Japan* 3, 209-17(1928).—The affinity of transition (Z) and the heat of transition (X) from diamond to graphite and from white to red P have been evaluated on the basis of the Nernst theory. Under atmospheric pressure, they are monotropic changes. The former case will probably be enantiotropic under high pressure, whereas the latter case will remain monotropic. For diamond to graphite, if T (in °K.) is 0, 100, 200, 300, 400, 500, 600, 700, 800, 900, 1000, 1100; X (in cal. gr. atom) is 277, 264, 212, 150, 11, 62, 35, 1, 890, 377,

formula for the heat of transition of transition the dimorphism in Fe_2O_3 , ICl , benzophenone, phthalide, bromonitrobenzene, acetamide, chloroacetic acid, nitro-*p*-toluidine and erythritol have been estd. to be monotropic.

A. I. HENNE

Thermal study of a few mixtures of incompatible components. ANTONIO ANGEL-ETTI. *Giorn. farm. chim.* 77, 97-113(1928).—Incompatible means here forming eutectics at room temp. The expts. were carried out with 10 g. substance in a Beckmann tube. Readings were made every 10 sec. *Acetanilide* (I) - *resorcinol* forms a eutectic with 53.9% I at 24°. The sepn. of the eutectic is assocd. with supersatn. phenomena. All mixts. with 20-90% I are liquid or pasty above 24°. *I-phenol*: eutectic at -14° with 38.6% I. The other eutectics were not detd. because of the high viscosity. *I-thymol*: eutectic with 33.3% I at 24.5°. Mixts. with 60-40% I show marked undercooling on solidification of the eutectics. Solid solns. are formed with 100-70% I. *I-chloral hydrate* shows for 35-42.5% I a gap in the miscibility. Mixts. with 100-70% I had to be heated above the decompn. point of chloral hydrate. There is a eutectic with 42.7% I at 25° and another with 31.5% I at 18°. Above this temp. only pasty or liquid mixts. are obtained. *Salol-methylacetanilide* forms a eutectic with 79% salol at 29°. At 20.0% salol solid white cryst. solns. are obtained. *Salol-naphthalene*: eutectic with 21.2% naphthalene at 24.5°. *Salol-terpinol hydrate*: Only mixts. up to 30% terpinol hydrate could be prepd., since temp. over 100° must be avoided. Eutectic: 97% salol, 39°. *Antipyrine-menthol*: eutectic at 33° with 18.9% antipyrine. *Antipyrine-methylacetanilide*: eutectic at 73.5° with 51% methylacetanilide. Above 80 and below 30% antipyrine solid mixts. are formed. All mixts. with a hygroscopic component gradually liquefy below the eutectic point.

MARY JACOBSEN

The precise determination of thermal capacities with particular reference to that of molybdenum. T. E. STERN. Princeton Univ. *Phys. Rev.* 32, 298-301(1928).—A Bunsen ice calorimeter modified by the addn. of a silvered vacuum jacket yielded precise values of the total heats of substances. The falling body was contained in a metal capsule to eliminate errors due to radiation and convection during fall. Thermal contact was established in the calorimeter by a Cu cup, contg. H_2O or Hg, and surrounded by H_2O . The probable error of a single observation of the motion of the Hg thread caused by a hot body was about 1 part in 1000. By this method the sp. heat of Mo was found to be $C_p = 0.05973 + 0.00001619t$ mean cal. between the temps. of 0° and 444.5°.

BERNARD LEWIS

A simple relation between thermal conductivity, specific heat and absolute temperature. C. C. BIDWELL. Lehigh Univ. *Phys. Rev.* 32, 311-4(1928).—A relation of the form $k/aC = K_1/T + K_2$ between thermal cond. k , at. heat (aC) and abs. temp. T , is shown to hold for Zn, Na, Li, Cu, Pb, Al and Hg. The possibility is indicated of an equation of this sort based on the assumption of a double mechanism of heat conduction—an at. lattice along with energy is transmitted as elastic waves (Debye) and a structure of atoms (cryst. or amorphous), through which energy is transferred by impacts. The lattice and at. contributions to the thermal cond. may be obtained from the slopes and intercepts of the lines. The values at 0° C. are as follows (lattice part being given first): Li 0.150, 0.006; Na 0.092, 0.169; Zn 0.084, 0.192; Cu 0.920, 0.171; Pb 0.018, 0.068; Al 0.127, 0.358; Hg 0.031, 0.033. The line for Hg suggests that the at. part is at least approx. the cond. in the liquid state. The single and polycryst. Zn lines have

the same intercept but different slopes, indicating that the increased thermal cond. of the single-crystal specimen is in the elastic wave contribution. **BERNARD LEWIS**

Entropy and oscillation number of solid inorganic compounds. W. HERZ. Bröslau. *Z. anorg. allgem. Chem.* 175, 245-8(1928).—The product of entropy and square root of the oscillation no. ($S\sqrt{\nu}$) is a const. for a no. of binary and ternary inorg. salts. The entropy was calcd. from Latimer's formula $S = \frac{1}{2}R \log A - 0.94$ (cf. C. A. 15, 1842).

EMIL KLARMANN

Calculation of the heat of dilution in accordance with the Debye-Hückel theory. G. B. BONINO AND V. VAGLIO. *Nuovo cimento* [N. S.] 5, 115-26(1928).—Evidence is presented to show the value of the Debye-Hückel theory as a means of calcg. heat of diln. The math. expression of the theory is interpreted as considering the heat of diln. not as proportional only to the square root of the concn., but as the sum of two terms one of which is proportional to the square root and the other to the first power of the concn. itself. The calcd. values for heat of diln. on this basis of KNO_3 , NaCl and LiCl compare as a satisfactory approximation with observed values reported in the literature.

L. T. FAIRHALL

Contribution to the thermodynamics of mixtures. V. FISCHER. *Z. Physik* 50, 419-24(1928); cf. C. A. 22, 1892.—Temp. and vol. are taken as the independent variables in equations for mixts. Free energy, internal energy and heat content are introduced into the equil. conditions for a mixt. of two components. Equations with pressure and vol. as the independent variables are also given.

E. R. SMITH

Use of the quinhydrone electrode. R. R. MCKIBBIN AND L. I. PUGSLEY. *Can. Chem. Met.* 12, 283-6(1928).—The history of this method for detg. H-ion concn., comparison with the hydrogen-electrode method, construction of the gold electrode devised by Cullen, and some of the conditions to be taken into account in using the hydroquinone \rightleftharpoons quinone method are given together with a cut of the set-up. The p_H obtained by both the above methods for a number of colored fruit juices, animal body fluids, one moistened soil and one buffered soln. are tabulated. Where the liquid was not too deeply colored, the p_H as shown by selected indicators is also given. The general principles of the quinhydrone method are given and the procedure followed by McK. and P. in detail. For plant fluids the quinhydrone method gave slightly higher figures than the hydrogen electrode. The quinhydrone method was much more rapid. With undil. human saliva the agreement was very poor. With the moist soil and the buffer the agreement was good. A short list of references is included.

E. G. R. ARDAGH

The electromotive force between copper and its amalgam and the reproducibility of the copper electrode. MITSUGU OKU. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 905-14, English Ed. 1, 84-6(1928).—Previous detns. of the e. m. f. between Cu and its amalgam lack accuracy, because the Cu electrode could never be reproduced. O. succeeded in preparing a reliable Cu electrode. A soln. of CuSO_4 (about 0.1 M) acidified with H_2SO_4 was electrolyzed with a Pt cathode and a Cu anode, the c. d. being kept at 0.5-1.0 amp./sq. cm.; the electrolytic Cu thus produced was in a very spongy form and was further kept in the acidified CuSO_4 soln. for some days, during which the adhering H was removed by occasional shaking. The e. m. f. of the combination $\text{Cu}|\text{CuSO}_4 \text{ soln.}|\text{Cu amalgam}$ (heterogeneous) was measured at 25°, with great precaution against the oxidation of the electrodes by air. The mean value was 0.00513 ± 0.00005 v. when the electrolyte contained 1.0 mol. and 0.00511 ± 0.00003 v. when it contained only 0.5 mol. The temp. coeff. was detd. by measuring the e. m. f. at various temps. between 0° and 40°; the e. m. f. is strictly a linear function of the temp.; $dE/dT = -0.0000737$ v./degree; so that for Cu-Cu amalgam (heterogeneous), $\Delta F_{298} = -236.3$ cal. and $\Delta H_{298} = -1250$ cal. The reproducibility of the Cu electrode is perfect. The electrolytic Cu produced by the electrolysis of a neutral soln. (Lewis and Lacey, C. A. 8, 2839) lacks in reproducibility, but after being kept in an acidified CuSO_4 soln. it gave the same e. m. f. as mentioned above. Cu powder obtained by the reduction of CuO with H shows a high and consistent e. m. f., but this defect may be removed by treating with acidified CuSO_4 . Many previous detns. of the e. m. f., were defective because the electrodes were not properly protected against oxidation.

A. L. HENNE

The Hall effect in very intense magnetic fields. ALESSANDRO MAZZARI. *Nuovo cimento* [N. S.] 5, 215-23(1928).—M. has measured the Hall coeff. of Bi in magnetic fields varying from 11,900 to 36,500 gauss. The value of the coeff. R beginning at -3.44 at 11,900 gauss changes more or less regularly to -2.64 at 29,800 gauss, from which point it remains more or less const. Its value at 36,500 gauss is -2.63 . **L. T. F.**

Eliminating eye estimates from color measurements. L. BLIN DUBARDET. *J. Soc. Dyers Colourists* 44, 327-35(1928).—Curves were drawn with wave lengths as abscissas and intensity of tone as ordinates, a white plaster surface being taken as a standard

at 100 and abs. black as zero. The "Toussaint Photoelectric Photocolorimeter" for detg. the values to be used in the construction of the curves is illustrated and described. The results are shown in 12 charts of curves. L. W. RIGGS

The preparation of thin sections of friable rock. MAX LÉGETTE. *J. Geol.* 36, 549-57(1928).—A friable rock when impregnated with bakelite varnish and then heated in an oven produces a sound rock chip from which sections can easily be made. MeOH and a few drops of acetone are used as a solvent for the varnish. The n of the bakelite varies from 1.60 to 1.64. The technic is described in detail. W. F. H.

The sun's outer atmosphere. EDWARD A. MILNE. *Proc. Roy. Inst. Gr. Britain* 25, 404-12(1928); cf. *C. A.* 22, 2887.—The depth of the photosphere is estd. as tens of km.; that of the reversing layer as hundreds of km., that of the chromosphere as thousands of km.; that of the corona as hundreds of thousands of km. The limits of the photosphere are defined by pressures from 10^{-6} to 10^{-8} atm. Conditions governing radiation in the strata are discussed. A. E. BADGER

Wolfram, not tungsten. Vanadium or erythronium. F. MOLES. *Anales soc. españ. fis. quim.* 26, 234-52(1928).—Original literature shows that the name tungsten for element 74 is not justified. V was discovered by Del Rio, who called it erythronium because of the red color of its oxide. E. M. SYMMES

Milliliter or cubic centimeter? W. H. LINNELL. *Pharm. J.* 121, 423(1928).—The non-identity of the two terms is explained. The best recently detd. equiv. is 1 l. = 1000.028 cc. "Although the difference between cc. and ml. is negligible for general purposes, the use of the ml. should be encouraged because it will tend to concentrate attention on the true meaning of the terms." The term ml. for unit of vol. became official in Brit. Pharm. 1914. S. WALDBOTT

Constitution of hydroxides and hydrates (NATTA) 6.

3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

S. C. LIND

Packing effect and characteristic nuclear size. L. STRUM. *Z. Physik* 50, 555-8 (1928).—H is chosen as the unit and upon this basis the "packing effect" is calcd. for a no. of elements. The relationship of the effect is not linearly proportional to the no. of protons in the nucleus, but nearly so. A mode of calcn. of the packing effect and

energy involved upon the basis of Frenkel's formula, $U = \frac{1}{2} \sum_{\alpha=1}^n \sum_{\beta=1}^n \frac{e_{\alpha} e_{\beta}}{r_{\alpha\beta}}$, for the total potential energy of the particles composing the nucleus, and of the Virial theorem, is derived. WILLIAM E. VAUGHAN

Jollivet-Castelot's process of transmutation. An attempt to explain. A. LÉLEVÉ. *Ann. chim. anal. chim. appl.* 10, 285-7(1928).—Jollivet-Castelot claims to be able to form Au from Ag, Sn and sulfides of As and Sb (*C. A.* 22, 3619). This is noteworthy because it represents the formation of an element with at. no. 79 from elements having at. nos. 16, 33, 47, 50 and 51. Methods of Rutherford and his followers have resulted in at. disintegration, whereas this appears to be a case of at. synthesis. It is easy to see how it would be possible to obtain the requisite protons and electrons from As and either Sb or Sn. If the nucleus of the atom is once opened there is probably enough energy available to accomplish the regrouping of electrons and protons, which is assumably a reaction of endothermic nature. In some way not yet clear, Ag seems to catalyze the reaction. W. T. H.

Helium studies. II. Application of the sensitive helium determination to the problem of the transformation of elements. FRITZ PANETH AND KURT PETERS. Univ. Berlin. *Z. physik. Chem., Abt. B*, 1, 170-91(1928); cf. *C. A.* 22, 3110.—P. and P. utilize their sensitive He-detection app. in attempts to identify He as a product of decompn. of elements. Several methods were tried: bombardment of KCl, KI and KBr with cathode rays for long periods of time; elec. discharges through H₂ at various pressures by use of metal electrodes, H₂ electrodes and ozonizers; application of β and γ rays upon H₂ and Hg in various ways, such as by the decompn. of Th B and Th C. The results obtained are considered as decidedly neg., only such amts. as are indicated by

vols. of 10^{-3} cc. being detected, this probably being occluded gases. The exptl. detail and data are given, with a rather complete bibliography of the field. W. E. V.

The separation of isotopes and a further separation of mercury by evaporative diffusion. WILLIAM D. HARKINS AND BERNARD MORTIMER. Univ. of Chicago. *Phil. Mag.* 6, [7], 601-31(1928).—A comprehensive survey of the sepp. of isotopes actually achieved has been made, and the possibilities of any larger sepps. have been discussed. The difference of at. wt. between samples of Hg as obtained in this work is 0.189 unit, the largest difference in at. wt. yet achieved by artificial means. The app. developed by Harkins and Mulliken (*C. A.* 16, 1359) was modified by the introduction of a ground joint between the flask and condenser, which greatly reduced the time of repair and replacement of the filter-paper membrane. *The theory of isotopic resolution by evapn. and diffusion is briefly reviewed. It is shown that the change in at. wt., ΔM , depends largely on the sepn. coeff., the cut and the efficiency. The details of the method of systematic fractionation, with cuts of 2, used in this work, are given in detail. The time required for the production of any extreme fraction, allowing for the time necessary to build up the intermediate fractions, is given by $t = K(\Delta M)^2 Q_0 / DE^2 B^2$, in which K is a const., B the sepn. coeff., E the efficiency, and D the rate of production of the light fraction. Study of this equation shows the difficulty of obtaining large values of ΔM , especially if B is small, as it is with Hg. The completion of nine full rows of the fractionation scheme applied to the heavy fraction yielded 101.96 g., 0.0962 unit of at. wt. heavier than ordinary Hg, and a set of 23 fractions each 0.004 unit heavier progressively than ordinary Hg. The completion of 13 full rows of the fractionation scheme applied to the light fraction yielded 108.76 g. of Hg 0.0931 unit lighter than the ordinary element; in addn. there is the corresponding set of 23 fractions, each progressively 0.004 unit lighter than ordinary Hg. The existence of this isotopic Hg affords an opportunity for the investigation of the variation of properties with isotopic compn.

GEORGE CLOCKLER

The first separation of chlorine isotopes. WM. D. HARKINS AND CLARENCE E. BROEGER. Univ. of Chicago. *Z. Physik* 50, 537-47(1928); cf. *C. A.* 14, 1480, 2123; 16, 196; 20, 8.—This constitutes a comprehensive description of H.'s work on the sepn. of Cl isotopes, a research initiated in 1916-17. The essential method consists in passing a continuous stream of pure HCl gas through 12.2 m. of porous porcelain pipe-stems; $10/20$ of the gas diffused through the pores of the clay, while $1/10$ passed out of the end over water where it dissolves. The so-called "cut" in this case is 20 and the portion ($1/20$) which passed through the tubes is designated "the heavy fraction." The "fractionation" of the "heavy fraction" was continued 3 times, the total cut being 8000. The increase of at. wt. of the Cl in the heavy fraction was detd. for 5 sepps. and found to be 0.052, 0.059, 0.057, 0.055 and 0.053 (av. 0.055). This increase amounts to 60% of the theoretical as predicted by Rayleigh's theory of diffusion, which does not necessarily apply to the method used. A plot of the extent of the sepn. according to theory and a complete diagrammatic sketch of the app. are given. The increase in the at. wt. was detd. very accurately by comparison of the ds. of solns. of equal molar strength of the "isotopic" HCl and of ordinary HCl. The accuracy of these detns. is estd. as 0.001 or 0.002 units of at. wt. ΔA , the increase, is given by $36.468 \Delta W / W_e$, where ΔW is the difference in wt. of the equal vols. of the 2 HCl solns. and W_e is the wt. of the soln. of ordinary HCl; or by $[T_e / (T_e - 1)] (d_{HCl} - d_{H_2O}) / d_{HCl}$, where T_e and T_i are the strengths of the ordinary and "isotopic" solns. and d_{HCl} and d_{H_2O} the wts. of HCl and water in the soln. of ordinary HCl.

WILLIAM E. VAUGHAN

The isotopic system. II. GUIDO BRÜCK. Univ. Wien. *Z. Physik* 50, 548-54 (1928), cf. *C. A.* 22, 2314.—B. attempts to develop a picture of the structure of isotopes, especially of the nuclei, utilizing as "building blocks" protons, electrons and α -particles, employing the latter as discrete units. Particular attention is given to those isotopes of at. wt. $4n$, n being any no. By using quantum considerations, such as the Pauli principle of limitation of not more than 2 electrons in 1 quantum state, and utilizing reasoning to allow for the inaccuracy of the Coulomb law in the near vicinity of the nucleus, there are developed conditions for the stability of various new orbital states. The no. of stable orbits is a function of P , the no. of effective charges in the kernel. Shift in outer-shell electrons to stable positions nearer the nucleus is exemplified with Ca of wt. 40, which by motion of 2 electrons toward the kernel into a stable state, would result in its isobar, A of wt. 40. The no. of these isobaric states, B , is given by $1/2$ of the no. of electrons added to the nucleus, since the shift of each pair results in but one new orbit, in which the electrons rotate in opposite directions. A plot of B vs. P gives a parabolic curve for 18 isotopes of wt. $4n$.

WILLIAM E. VAUGHAN

Wave mechanics and radioactive disintegration. RONALD W. GURNEY AND

EDW. U. CONDON. Princeton Univ. *Nature* 122, 439(1928).—To explain radioactive decay it has hitherto been necessary to postulate some instability of the nucleus. It is pointed out that disintegration is a natural consequence of the laws of quantum mechanics without any special hypothesis. In the classical mechanics the orbit of a moving particle is entirely confined to those parts of space for which its potential energy is less than its total energy. If a ball be moving in a valley of potential energy and have not enough energy to get over a mountain on one side of the valley, it must certainly stay in the valley for all time, unless it acquires the deficiency in energy somehow. But this is not so in quantum mechanics. It will have a small but finite chance of slipping through the mountain and escaping from the valley. According to this view the α -particle is not hurled from a nucleus with explosive violence, but rather slips away almost unnoticed.

JAMES M. BELL

The constancy of the activity of radioactive preparations. HANS J. VOGLER. *Physik. Z.* 29, 678-81(1928).—The ionization of the air from the action of radioactive substances is not const. but undergoes considerable fluctuations during the course of a day. The results vary with different ionizers and with the kind of exptl. arrangement. The course of the curve is analogous to that of the cond. of the atm. at the same time. There is no theoretical discussion.

MARIE FARNSWORTH

An attempt to accelerate the rate of radioactive transformation. H. HERSZFINKIEL AND L. WERTENSTEIN. *Nature* 122, 504(1928).—The expt. of Danysz and Wertenstein was repeated. Three similar sources, each contg. 1 mg. of ThO_2 , were prepd. Two were irradiated with 28 millicuries of Rn. On comparing activity of three sources no change of activity within 2% could be detected.

L. D. ROBERTS

Condition of radium salts after storage in sealed glass tubes. A. G. FRANCIS AND A. T. PARSONS. *Nature* 122, 571(1928).—No pressure was developed in glass tubes contg. RaCl_2 and RaBr_2 which had been sealed for 7 years. The salts had been dried at 240° before sealing. A fine Pt wire was fused into the tube. The cotton-wool packing and the labels were disintegrated.

L. D. ROBERTS

Experimental evidence of the existence of aggregates of active-deposit atoms in gases containing radon. E. L. HARRINGTON. Univ. of Saskatchewan. *Phil. Mag.* 6, [7], 685-95(1928).—Exptl. evidence is given of the existence of aggregates of atoms of active deposit in mixts. of Rn and air, also of Rn and A, including in either case more or less water-vapor. The evidence is both direct and indirect. Photographic evidence as to the nature and variety of these aggregates is included. Suggestions as to the possible origin of these aggregates seem to account for the facts exptly. obtained by various observers.

GEORGE GLOCKLER

The formation of a gaseous helide of radium active deposit. D. M. MORRISON. *Proc. Cambridge Phil. Soc.* 24, 268-75(1928).—In the light of the hypothesis that the He atom can exist in a H-like form in which one electron is relatively far removed from the nucleus with respect to the other, a series of expts. has been carried out with a view to det. whether or not He could be obtained in the form of a compd. similar to certain known hydrides. The mass of evidence points to a positive result. A gaseous compd. was shown to form when excited He was passed over a strong source of the active Ra deposit. Compd. formation was proved by counting scintillations caused by the transportation of the radioactive material from the discharge tube into a bulb contg. a ZnS screen. It has been proved that the effect observed in the bulb was due to the presence of a gaseous radioactive helide and not to Rn or solid particles in suspension. It was shown to be very unlikely that the effect was due to H impurities in He. The compd. in H was more efficiently condensed by a CO_2 -ether mixt. than that in He. The catalytic effects of tap grease and Hg vapor on the reaction were noted.

A. L. HENNE

Electrolysis of radioactive B- and C-products and of polonium. HARRY RAUDNITZ. Inst. für Radiumforschung, Vienna. *Sitzb. Akad. Wiss. Wien Abt. II*, 136, 447-51(1928).—In order to obtain a view on the colloidal properties of Ra C and Po, the electrolytic isolation of these two elements has been studied, as a function of the acid concn. in the soln. Ra C nearly free of Ra B is obtained at the cathode when a 0.5 N HCl soln. is used as electrolyte. The electrolysis of radioactive $\text{Pb}(\text{NO}_3)_2$ solns. gives also an optimum Po deposit at the cathode when the acidity of the electrolyte is 0.5 N HCl.

A. L. HENNE

The photographic action of H-rays. MARIETTA BLAU. Inst. für Radiumforschung, Wien. *Sitzb. Akad. Wiss. Wien Abt. II*, 136, 460-80(1928); cf. *C. A.* 21, 2612; 22, 3841.—An app. is described for the photography of natural H particles. It easily gives a great no. of definite point series. It is shown that the AgBr particles of the point series lie closer when they are caused by H radiation than when they are caused by α -rays. The length of the point series is a measure of the remaining range of the active

H particles, although only a small point series. H rays from _____ating atoms could be _____ly detected by means of the retrograde method. Even numerically, the results were in accordance with the results obtained previously in Vienna by the scintillation method and give addnl. support to the assumption that the C atom can also be disintegrated.

A. L. HENNE

Action of the Geiger α -particle counter. JAMES TAYLOR. *Proc. Cambridge Phil. Soc.* 24, 251-8(1928).—The action of the counter is developed from 3 bases: the threshold current hypothesis; the shape and significance of the volt-ampere characteristic; and the photoelec. theory of sparking potentials. The theory explains the following points: the action of the gas, and the electrode shape; the fact that the counter can be used for radiation intensity as well as for α - and β -particle detection, and the fact that the counters are much more efficient for α -particle counting than for β -particle counting (provided that the counter is not too critically adjusted); the fact that plane parallel electrode tubes can be used as counters; the partial reversibility of the counters; the self-restoring property of the system.

A. L. HENNE

Relation between mean stopping power and mean range of β -rays. E. J. WILLIAMS. *Proc. Cambridge Phil. Soc.* 24, 315-9(1928).—Mathematical.

A. L. HENNE

The velocity and distribution of β -particles after passing through thin foils. P. WHITE AND G. MILLINGTON. Clara College, Cambridge. *Proc. Roy. Soc. (London)* A120, 701-26.—The velocity distribution of β -rays ($H\beta$ 1410 to 1938) which have passed through sheets of mica (2 to 6 mg. per sq. cm.) has been found by photometry of a magnetic spectrum and the results expressed in terms of a fundamental straggling curve. The relation between most probable loss of velocity and thickness of stopping material has been investigated for $H\beta$ 1410 to 5904, and surface density 2 to 14 mg. per sq. cm., and has been found to show a small systematic divergence from Bohr's theory, which is beyond the limits of exptl. error. The same has been found of the relation between initial velocity and most probable loss of velocity.

G. CALINGAERT

Color change of pressed salt. KARL PRZIBRAM. *Inst. für Radiumforschung, Wien Sitzb. Akad. Wiss. Wien Abt. II*, 136, 345-6(1927); cf. *C. A.* 22, 1532.—A blue NaCl crystal becomes yellow after having been powdered, then pressed again; after exposure to light it recovers its blue color. Natural blue salt, or crystals which became blue after Ra irradiation and heating, turn violet by compression, without becoming first yellow. Fluorite becomes blue by irradiation, and calcite yellow; when they have been compressed, irradiation makes them purple. Many commercial salts have been examd. When they are first compressed, irradiation develops a color slightly different from the color obtained without compression, but the color is always purple or turquoise-blue. K_2SO_4 is hardly colored if not submitted to pressure; it becomes green when it has been melted, allowed to solidify, then irradiated; if it is compressed instead of melted, it becomes purple. NaF, Na_2CO_3 , K_2CO_3 , $CaCO_3$, $BaCO_3$, Na_2SO_4 , $SrSO_4$, and $BaSO_4$ are not colored by irradiation alone, but become blue or purple after compression followed by irradiation.

A. L. HENNE

Artificial blue coloration of rock salt at room temperature. KARL PRZIBRAM. *Anz. Akad. Wiss. Wien* 63, 150-1(1926); cf. *C. A.* 18, 1781; 22, 28.—An artificial blue coloration of NaCl crystals is obtained when the salt is compressed to its limit before or after being treated with Ra rays, and is then exposed for a few hrs. to daylight. Heating the salt to 150° before exposing it to the Ra rays inhibits the phenomenon.

A. L. HENNE

Relation between the scintillations and the structure of zinc sulfide. The cause of the scintillation process. BERTA KARLIK. *Sitzb. Akad. Wiss. Wien Abt. II*, 136, 331-61(1927).—K. describes a photometric method by means of which the relation between the residual range of the α -particles and the brightness of the scintillations can be detd. by differently prepd. ZnS-Cu phosphors. The influence of size of grain has been studied and curves have been obtained showing the relation between the residual range and the brightness on a no. of different specimens. It is shown that the form of the curves can be explained by assuming that the brightness of the scintillations is proportional to the total no. of ions produced in the passage of the α -particle through the ZnS crystal. This confirms the view that a scintillation depends on an action on the Lenard centers in the phosphore, which in each element of the path is proportional to the ionization produced. The effect of optical absorption and reflection in the crystal was studied and found to be small. The differences of brightness of the scintillations in the same prepn. was studied.

A. L. HENNE

Theory of the color change of rock salt by Becquerel rays. K. PRZIBRAM. *Inst. für Radiumforschung, Wien Sitzb. Akad. Wiss. Wien Abt. IIa*, 136, 679-84(1927);

cf. C. A. 21, 1411.—The observed relation between the coloration of NaCl and the irradiation intensity is further explained by the assumption of the simultaneous presence of 2 kinds of color centers of different stabilities, of which the more stable is more easily decolorized by the dark reaction than by irradiation. A theory is developed, based on the existence of color centers which can be destroyed and regenerated; this theory also gives an explanation of the luminescence phenomena. A. L. HENNE

Natural blue rock salt. KARL PRZIBRAM. Inst. für Radiumforschung, Wien. *Sitzb. Akad. Wiss. Wien Abt. IIa*, 136, 685-8(1927); cf. C. A. 22, 28.—The examn. of the macroscopic colorless halos on certain faces of naturally blue rock salt crystals sustains the assumption that the pressure has an important role in the coloration. A. L. HENNE

The dynamics of an electron. D. MEKSYN. King's College, London. *Phil. Mag.* [7], 6, 977-91(1928).—Mathematical. GEORGE GLOCKLER

The number of impacts associated with the diffusion of slow electrons in an electric field. W. HARRIES AND G. HERTZ. *Z. Physik* 46, 177-87(1928).—The no. of impacts of slow electrons in a rare gas calcd. with reference to the no. of electrons captured by the collecting plate is shown to be dependent only very slightly upon the strength of the field employed, although the no. of these electrons depends very largely upon the strength of the elec. field. Diffusion in a field-free cylindrical condenser and the Ramsauer effect are also discussed. A. L. HENNE

Collision of two-point charges according to wave mechanics. W. GORDON. *Z. Physik* 48, 180-91(1928).—The Rutherford scattering expt. is considered, by means of wave mechanics, on the line of Born's work. The Rutherford formula for the distribution of scattered α -particles is shown to hold good for arbitrary velocities. A. L. H.

Dissociation energy of nitrogen. GERHARD HERZBERG. *Nature* 122, 505-6(1928).—Gaviola's value of 9.8 v. (C. A. 22, 4370) for the dissocn. energy of N_2 is confirmed. It is suggested that Spomer's interpretation of the afterglow be altered. L. D. ROBERTS

Entropy of electron-gas calculated upon the basis of Fermi's statistics. ALLAN C. G. MITCHELL. Inst. Physik, München. *Z. Physik* 50, 570-6(1928).—Basing his calcs. upon Fermi's statistics, M. detrs. the entropy of electron-gas at various temps., considering the material to be a dissocd. gas; this condition increases with rise of temp. A value of 5.43 cal./mol./deg. for S_{298} is obtained. The detn. and value of A , which is the deg. of dissocn. of the material, is a factor upon which the entire derivation is highly dependent. The Sackur-Tetrode formula, $S = 5/2 R \log T + 3/2 R \log M - R \log P + R \log ((2\pi)^{3/2} K^{3/2} e^{5/2}) / (\lambda^3 N^{3/2})$, gives 3.28 cal./mol./deg. This "classical" expression is corrected by M. through addn. of a term $+R \log G$, where G is the "quantum wt." given the electron; in this case $G = 2$. This factor G is independent of the mode of derivation, whether by classical, Bose-Einstein, or Fermi's statistics. The corrected value of the S.-T. equation is 4.98 cal./mol./deg. However, the entropy of the gas is 0 at 109.2° K. according to this amended formula and is, obviously, of a neg. value at temps. lower than 109.2° K. Fermi's statistics give an entropy of 0 at 0° K., in accord with the "Third Law." Much more exptl. work is necessary for strict and rigorous proof of this problem. W. E. V.

Theory of the diffraction of electrons in crystals. H. BETHE. *Ann. Physik* 87, 55-129(1928); cf. C. A. 21, 1927; 22, 538, 2511.—A mathematical explanation, from the Schrödinger equation, of the expts. by Davisson and Germer and others on the selective reflection of electrons from crystal faces. B. reconciles the discrepancy between the de Broglie wave length within the crystal, Δ , and that calcd. from the Bragg equation, λ , by postulating an index of refraction $\mu = \Delta/\lambda$, which is greater than 1. The diffraction potential for Ni is calcd. from D. and G.'s results as 14.8 v. The theoretical development of the Richardson work function, the diffraction potential, the Fourier coeff. of the potential, and in calcd. examples the numerical values of the reflecting and resolving power of crystals agree satisfactorily with expt. G. M. E.

Degradation of gaseous electrons within stars. WILHELM ANDERSON. *Z. Physik* 50, 874-7(1928).—If p = pressure, n = no. of mols./cc., R = Boltzmann's const., T = abs. temp., m = mass of the mol., h = Planck's const., then for ideal gases, $p = nkT$ (i). For weak degradation the equation is $p = nKT (1 + 1/16(h^2 n)/(\pi m K^{3/2})) + \dots$ (ii) and for strong degradation $p = 1/20(6/\pi)^{3/2} h^2 n^{3/2}/m + 2^{3/2} \pi^{3/2} / 3^{3/2} m^{3/2} k^2 T^2/h^2 + \dots$ (iii). In shooting stars the central density is 5425 times as great as the av. density. In many denser dwarf stars the law cannot hold because such gases can only be compressed to a definite limiting density. Within dense stars like Sirius B it must be assumed that practically all the atoms are ionized and the real vol. of such strongly ionized gases is relatively very small; hence even with very dense stars the gas

can be still treated as ideal. Assuming the inside of stars to be Fe, one has $32,468 \times 10^4$ atoms/cc. On complete ionization 26 free electrons per Fe atom are lost, i. e., 844×10^{10} electrons/cc. Putting this for n in (ii) and $T = 7 \times 10^7$, $p = 9 \times 10^{-10}$, $h = 6.55 \times 10^{-27}$, $av k = 1.372 \times 10^{-16}$, then $p = 8.172 \times 10^{17}$ dynes/sq. cm., while from (i) $p = 8.107 \times 10^{17}$ dynes/sq. cm., or a difference of 1%. With less complete ionization the difference is even smaller and hence the degradation of gaseous electrons must be small. The degradation is found to be small in the chief star of Sirius. Similar calcs. for Krüger B show that the degradation p is about 2.05 larger than the classical p . If the 2 electrons in the K shell of Fe remain, then degraded p : classical $p = 1.97$. If in addn., the 8 electrons in the L shell remain, the ratio becomes 1.64. From (iii), p for Sirius B is less than h from (ii). Equation (iii) shows that a degraded gas must have a finite pressure even at zero abs. The degradation of gaseous electrons within our sun and many other stars is so small that it may be neglected. In stars of unusual density, e. g., Sirius B, the degradation cannot be neglected or serious error may be committed. Eddington's theory makes the center of the star be 50 times the mean density. Kerr Grant makes it nearer 50×10^6 times as great and according to this, the pressure and energy at zero abs. of gaseous electrons in the sun must be very large.

S. L. B. ETHERTON

A determination of a limit of the number of free electrons in a metal. F. EVELYN COLPITTS. *J. Franklin Inst.* 206, 489-50 (1928).—The existence of free electrons plays an important role in a no. of theories of metallic conduction. C. detd. the no. of free electrons on the basis of a suggestion in J. J. Thomson's Corpuscular Theory of Matter. The lower limit of the no. of free electrons in Au was found to be of the order of magnitude of 2×10^{17} /cc. and in W 9×10^{16} /cc. For details of app. consult the original.

EMIL KLARMANN

The high-frequency electric discharge at low pressures. JAMES TAYLOR AND WILFRID TAYLOR. *Proc. Cambridge Phil. Soc.* 24, 259-67 (1928).—Expts. have been conducted upon elec. discharges through gases under the influence of oscillations of the order of 10^7 cycles per sec. The following points are especially considered, in connection with the character of the discharge: effect of the wall material; general nature of the phenomenon; appearance of the discharge in narrow tubes; conduction of the luminosity along the tubes and round corners; elec. effect due to the wall; effect of injecting electrons into the glow; discharges in a bulb; effect of magnetic fields; clear-up effects and spectra.

A. L. HENNE

Reflection of electrons by insulators. A. WEHNELT. *Z. Physik* 48, 165-73 (1928).—W. publishes two dissertations written in 1922 in connection with his discovery of the reflection of electrons by insulators, which has recently been theoretically deduced by Klemperer. The number of secondary electrons emitted by glass and by other insulators increases with the angle of incidence. At potentials of 1300 to 3000 v. a well-marked diminution of the reflected current occurs at a certain angle. This is well accounted for on the wave theory of electrons.

A. L. HENNE

The reflection of electrons from an aluminum crystal. D. C. ROSE. *Phil. Mag.* [7], 6, 712-29 (1928).—Expts. have been performed in which electrons have been reflected by the planes of an Al crystal in the manner suggested by the wave theory. The app. was similar to a Bragg x-ray spectroscope, having the beam of x-rays replaced by a beam of electrons. It would be expected that a beam of electrons would be reflected in a manner analogous to x-rays when the accelerating potential, spacing const. of the crystal, and angle of reflection were connected by the usual relations $\lambda = h/mv$ and $n\lambda = 2d \sin \theta$. Four different orders of reflected beams were found whose position agreed with that predicted by theory within the accuracy of the expt. Two orders of another set of beams were found, which are attributed to Al_2O_3 or some other contamination of the surface of the crystal. A comparison is made between these expts. and those of Davisson and Gernier (*C. A.* 22, 350) who obtained different results with a Ni crystal. Their results differed from those predicted, but could be explained by the assumption of a refractive index.

GEORGE GLOCKLER

Equipment for routine spectral transmission and reflection measurements. H. J. McNICHOLAS. *Bur. Standards J. Res.* 1, 793-857 (1928).

Theoretical diagram of the stationary and transitory phases of electrical discharge in gases. GIORGIO VALLE. *Nuovo cimento* [N. S.] 5, 195-203 (1928).—A general discussion of recent investigations and theories of elec. discharge in gases illustrated diagrammatically. The diagram constitutes a means of synthetic representation of the phases of elec. discharge and of attendant phenomena.

L. T. FAIRHALL

The effective cross section of gas molecules against alkali ions of 1-30 volts velocity. CARL RAMSAUER AND OTTO BEECK. *Techn. Hochschule, Danzig-Langfuhr. Ann.*

Physik 87, 1-20(1928); cf. *C. A.* 15, 3933; 22, 1273.—The exptl. methods are those used in R.'s detn. of the cross section of gas mols., against slow-moving electrons. The results have been given previously. GREGG M. EVANS

New method for the determination of ionization potentials of elements. SENHAMOY DATTA AND SURESHCHANDRA SEN. Calcutta. *Z. Physik* 50, 849-60(1928).—Detns. of the ionization potentials of K, Na, Li, Mg, Ca, Sr, Ba and Hg were carried out by the new method and the results agreed with values from other methods. The new method of D. and S. combines thermal and elec. excitation; it measures the cond. of a flame colored with metal. An even flame is necessary and D. and S. found the atomizer of Bancroft and Weiser most convenient. Both Pt anode and cathode are in the flame; the anode about 1 cm. above the cathode is connected with the positive of a potentiometer. The cathode is connected with a rheostat through a high-resistance galvanometer. The best electron source was found to be a piece of Th gas mantle. It was placed upon the cathode and a concd. soln. of the desired metallic salt was then introduced. The reading (A) was taken on the galvanometer when the potential was varied from zero to a max, when no salt was present in the flame. This is the cond. due to the electrons. The salt was added and reading (B) obtained. This gave the increased cond. due to dissoed. metallic atoms and electronic collision of ionized atoms. The Th gauze was then removed and the reading (C) obtained; the cond. due to the thermal dissoen. of the metallic atoms, $B - C - A$, corresponds to the increase in cond. due to electronic collision of ionized atoms. The results agreed within the limits of exptl. error. The possibility of a free electron obtaining energy depends only on the partial pressure of the metallic vapor in the flame. This is small, of the order 10^{-6} , so that the actual free path will suffice for the purpose. Moreover, near the cathode, the potential gradient of the flame is large; hence the fall in potential per mean free path is much greater in this region. Therefore, in the applied field, the electrons attain the full velocity earlier before they collide for the first time with an atom. However, the degree of ionization must needs be small. Mg, Ca, Sr, Ba and Hg have 2 resonance lines corresponding to $1s-2p_1$, and $1s-2p_2$, in the old notation. Conclusion: In the flame, Mg may exist in the $2p_1$ and $2p$ states, Ca, Sr, Ba in the $2p_1$ state and Hg only in the $2p_2$ state; these views are confirmed by the flame spectra. S. L. B. ETHERTON

The ionization accompanying the oxidation of nitrogen dioxide. A. PINKUS AND L. HENRY. Univ. Brussels. *Bull. soc. chim. Belg.* 37, 285-303(1928).—The ionization accompanying the reversible oxidation of NO has been studied in an app. capable of indicating 10^{-15} amps. At room temp., and at 100° , replacing O by mixts. of NO + O or NO₂ + O in the ionizing chamber causes only temporary elec. effects, which are attributed to the different dielec. consts. of NO₂ and O₂. The same effect is obtained with HCl, but not with air or N, whose dielec. consts. are very similar to that of O. At about 300° , the reacting mixts. NO + O₂ are conductive, and give an ionization current of 10^{-14} — 5×10^{-13} amps. This is independent of the sign of the elec. field. The current intensity increases with the potential gradient and the proportion of NO or NO₂ (O₂ being always in excess). The phenomenon is not a thermionic effect. Conclusion: The reversible reaction $2NO + O_2 \rightleftharpoons 2NO_2$ is accompanied by the formation of pos. and neg. ions at 300° . The fact that the ionization cannot be detected at room temp., or even at 100° , seems to prove that the effect is due entirely to the dissoen. of NO₂. But it is possible that the neg. results at low temp. are due to adsorption of the NO₂ mols. by the electrodes; this would build an isolating pellicle; the ionization would then be detectable only at a temp. where the adsorption phenomenon becomes negligible. As a whole, the results agree with A. K. Brewer and F. Daniels (*J. Am. Electroch. Soc.* 44, 171(1923); cf. *C. A.* 17, 3458; 18, 2104).

A. L. HENNE

The ionization accompanying the thermic decomposition of ozone. A. PINKUS AND R. RUYSEN. Univ. Brussels. *Bull. soc. chim. Belg.* 37, 304-25(1928).—The thermic decompn. of O₃ is accompanied by the formation of pos. and neg. ions, causing the reacting gases to become appreciably conductive. It has been shown by expts. carried out below 250° that this cond. is to be attributed exclusively to the chem. reaction in the gaseous phase, and not to a thermionic effect. Ionization is also to be observed when the decompn. of O₃ is catalyzed by Cl at low temp. In a 845-v./cm. field, the ionization current increased from 1.2×10^{-12} to 1.1×10^{-11} amp. when the no. of O₃ mols. decomposed per sec. increased from 8.9×10^{16} to 7×10^{17} . The ratio n/m = no. of captured ions/no. of dissoed. mols., remained practically const. (close to 10^{-11}). The results were nearly the same in a positive and a negative field. A study of the variation of the ionization chamber shows that satn. currents are yet far from being reached in fields of about 3000 v./cm. A theory is proposed which explains

the mechanism of the thermic dissocn. of O_3 . This theory admits two consecutive steps: (a) ionization step, resulting from the impacts between the mols. of O_3 , yielding positive and negative ions of O; (b) recombination step, the ions yielding neutral mols. of O_2 . This interpretation explains the proportionality of the current and the no. of transformed mols., the low value of the ratio n/m and the difficulty of reaching satn. currents.

A. L. HENNE

Total actinometry with the photoelectric cell. IVO RANZI. *Nuovo cimento* [N. S.] 5, 234-8(1928).—R. describes an actinometer consisting of a photoelec. cell of K hydride in which the cathode is connected to the neg. pole of an accumulator and the anode in series with a Ag coulometer. The amt. of Ag transported by the current is used as an index of mean light intensity during a certain period of time. It furnishes a means of detg. the mean value for illumination and the value for the so-called light sum.

L. T. FAIRHALL

The photoelectric threshold and the heat of dissociation of the potassium molecule. R. W. DITCHBURN. *Proc. Cambridge Phil. Soc.* 24, 320-7(1928).—The absorption curves and the photo-ionization expts. agree to give a value for the mol. photoelec. threshold of $\lambda 2555 \pm 20$ A. U. If D.'s view of the ionization process is correct, the dissocn. energy is 0.505 ± 0.01 v. If the picture of the ionization is wrong, the dissocn. energy may be a little lower (a few hundredths of a v.). The corresponding heat of dissocn. is 11,400 cal. In the range of temp. 200-500° generally used in expts. on K vapor, the fraction assocd. varies from 10^{-4} to 10^{-2} . An equation for calcg. the fraction assocd. at any temp. was given in a previous paper (*C. A.* 22, 1278).

A. L. HENNE

The photoelectric properties of thin films of the alkali metals. N. R. CAMPBELL. *Phil. Mag.* [7], 6, 633-48(1928).—The thin films mainly studied are those produced by depositing an alkali metal on some other material, driving it off by heat, and subjecting the remaining film to a discharge in H_2 . By this process photoelec. cathodes can be produced that have very remarkable and stable sensitivity to red light; photoelec. currents can be obtained with light of $\lambda 8000$ A. U. of the same order as those obtained in normal K cells with light of $\lambda 4500$ A. U. The sensitivity depends very greatly on the material on which the film is deposited. The observations are closely related to those of Ives on the photoelec. properties of thin films and to those of the many workers who have investigated the effects of gas films on photoelec. emission. The surfaces concerned almost certainly consist of a succession of monomol. layers, similar to those of Cs and O_2 on W (Langmuir and Kingdon) or of Ba and O_2 or other gases (Ryde). But the conditions of their formation are exceedingly complex, and little progress has been made toward an analysis of their constitution. The observations seem to have an important bearing upon attempts to correlate thermionic and photoelec. emission.

GEORGE GLOCKLER

Spatial distribution of the electrons produced by polarized Röntgen rays. FRITZ KIRCHNER. *Ann. Physik* 84, 899-906(1928); cf. *C. A.* 21, 2604, 3309.—A continuance of the work previously described. The observed spatial distribution in a Wilson chamber cannot, as was thought by Watson, be explained in terms of scattering from the gas. The latest measurements by Loughridge for unpolarized rays shows that the form of the distribution is independent of the nature of the gas as was proved previously by K. for polarized radiation.

A. L. HENNE

The intensity distribution of the general and characteristic x-radiation from molybdenum. L. R. G. TRELOAR. Univ. of Reading. *Phil. Mag.* [7], 6, 1008-19(1928).—Measurements are given of the intensity distribution of the general radiation at various voltages, the corresponding intensities of the $K\alpha$ and $K\beta$ line radiation and the ratio of the homogeneous to the general radiation.

GEORGE GLOCKLER

Secondary normals for x-ray wave lengths. MANNE SIEGBAHN. Upsala. *Z. Physik* 50, 443-7(1928); cf. *C. A.* 22, 3352.—This is a criticism of Iwata's work on secondary normals. The previous detns. of the Mo $K\alpha_1$ wave length are reviewed. Iwata's results are not in good agreement. In particular, the data of Larsson (cf. *C. A.* 21, 2606) are very much more consistent and presumably therefore more reliable than those of Iwata. Iwata's value for the W $L\alpha_1$ line agrees very well with previous more accurate work by Friman though it is suggested that the Fe $K\alpha_1$ line would be a better standard in this region. In general, it is not important in wave-length measurements whether the rotating-crystal method or the wedge method is used. The important point is not how the spectrum is produced but how the measurements are made. The whole idea of secondary normals in x-ray spectroscopy is, however, a mistaken one based on the erroneous assumption that relative measurements can be made with greater accuracy than abs. ones.

A. W. KENNEY

Thermal degeneration of the x-ray halos in liquids and amorphous solids. S. S.

RAMASUBRAMANYAM. *Indian J. Physics* 3, 137-49(1928).—X-ray diffraction in a no. of liquids, *vis.*, cyclohexane, pentane and glycerol, as well as that of an amorphous substance (a synthetic hydrocarbon resin) at different temps. has been studied. As predicted by Raman and Ramanathan in 1923, 3 definite effects were observed on raising the temp.: (1) a visible contraction of the ring, (2) broadening of the ring and diffuseness of the edges, (3) a large amt. of internal scattering. It is pointed out that the first effect is due to thermal expansion of the liquid, since the distance between the mols. is increased thereby. The second effect is due to increased displacements of the mols. from their mean positions. The third effect is explained as due to local fluctuations of density of scattering electrons arising from the varying positions and orientations of the mols. within the liquid. On raising the temp., the compressibility increases and the fluctuations of electron density become larger and hence give rise to an increased scattering at small angles. In spherical or nearly spherical mols., this effect is limited, whereas in long-chain compds. it reaches its max. The case of the amorphous solid is similar to that of the liquid, once it passes the transition interval and melts completely, in conformity with the expectation of Raman and Ramanathan.

G. CALINGAERT

Relation between chemical constitution and x-ray K-absorption spectra. VII. General review of the results obtained. ORTO STELLING. *Z. Physik* 50, 506-30 (1928).—Different methods of measuring absorption edges lead to different recorded results by different workers, more particularly since some of the corrections are not made uniformly. The results obtained, particularly with P, S and Cl, by attempting to correlate absorption spectra and chem. compn. are reviewed at some length. Of all the P compds. investigated, none gives a longer wave length for the absorption limit than elementary P, and of the 3 allotropic forms, white P gives the softest edge. All those compds. in which the absorbing atom is in the same radical give the same absorption edge, regardless of the structure of the rest of the compd., *i. e.*, only those atoms immediately adjacent to the P atom influence the results. In general, the shift of the absorption edge is greater the larger the no. of inserted atoms or groups. As for the direction of the shift, the phosphate group has the hardest edge of all compds. investigated. N compds., where the N is attached to the P, come next; so that the substituting elements may be arranged in the order of decreasing hardness as follows. $O \rightarrow N \rightarrow H \rightarrow C \rightarrow (Cl^?)$. The results of S. and of Lindh on the S compds. are in excellent agreement. As the valence of S increases the absorption edge becomes harder. The wave length of the edge depends also on the nature of the group attached to the S; but it is not possible to generalize with certainty on the character of these effects. The sulfates give the edge of shortest wave length independently of the cation. The absorption edge of Cl has been studied in a large no. of compds. All Cl compds. give harder edges than the gaseous element. With increasing valence the absorption edge is shifted toward shorter wave lengths. For univalent Cl the wave length of the edge is dependent on the atom attached to the Cl. When Cl enters non-ionogenically into a complex ion, it gives 2 distinct absorption edges, of which the softer lies near the soft edge of the element itself, and the harder edge corresponds to that of ionic Cl. In org. compds. the absorption edge of the Cl is not appreciably influenced on the long-wave-length side by the radical attached to the Cl, but it is on the short-wave-length side. The absorption edges of the chlorates and perchlorates are independent of the metals. The explanation of the change of the absorption edge with constitution must be related to the structure of the atom, specifically to changes in the energy levels, which may be described as distortions or deformations of the atom. A comparison of ionic distances in lattices of the same type shows that greater ionic distances are usually assocd. with longer-wave-length absorption edges, for the same element. In general, those factors (ionic distances, lattice type, electron configuration, etc.) which influence "deformation" have the predicted effect on absorption edges.

A. W. KENNEY

The change of x-ray absorption spectra in crystal lattices. K. FAJANS. Chem. Lab. Bayer, Akad. Wiss., Munchen. *Z. Physik* 50, 531-6(1928).—A quant. investigation has been made of the analogy suggested by Stelling between the changes which take place in the wave lengths of the x-ray absorption edges on the one hand, and the mol. refraction of ions in the crystal lattice on the other. As a matter of fact, the inverse proportionality to the fourth power of the ionic distances in the lattice, which according to Fajans holds for the changes of the mol. refraction of an anion seem to hold also for the x-ray spectra. If this high exponent is established by measurements of increased precision, it will be evidence that the x-ray spectrum is also influenced by the polarization (deformation) of the ions in the lattice.

A. W. KENNEY

Excitation of mercury fluorescence with the mercury line 2536 A. U. S. PIENKOWSKI. Inst. for Exper. Physics, Warsaw Univ. *Z. Physik* 50, 787-92(1928).—The green fluorescence of Hg vapor can be obtained by illumination with many short-wave ultra-violet sparks, particularly from Al or Zn. The absorbing centers are Hg₂ mols. which, upon excitation, emit fluorescence by an intermediate process. Since the line 2536 A. U. can only excite Hg atoms, it must be assumed that the intermediate process begins with atom excitation. Since the luminescence spectra in the 2 cases are identical, the end conditions in both processes must be the same. Upon illuminating streaming Hg vapor an after-glow lasting up to 10⁻³ sec. is noticed in both excitation processes. P. investigates the period of darkness lasting from the moment of excitation to the moment of the emission of the luminescence using the Al spark and the Hg line method and showed the identity of the time of induction for both methods. Apparently, absorption in the band 2540 A. U. is responsible for the production of the green fluorescence with the Hg line 2536 A. U. A diagram and a description of the app. are given.

S. L. B. ETHERTON

The spectrum of potassium excited during its spontaneous combination with chlorine. L. A. RAMDAS. *Indian J. Physics* 3, 31-6(1928).—The paper gives data concerning the spectrum of K excited while it burns spontaneously in an atm. of Cl₂. The arc lines, an intense broad band in the red region (due to mols. of K) and a few feeble lines which appear to be the enhanced lines in the violet region are emitted. The explanation of these results has been attempted in a general way and the possibility of thermal excitation has been considered.

G. CALINGAERT

The absorption spectra and constitution of diazotates. L. CAMBI AND L. SZEGÖ. Univ. di Milano. *Ber.* 61, 2081-6(1928).—A continuation of the discussion between Hantzsch (C. A. 21, 1970) and Angeli (C. A. 21, 3603) on the constitution of diazo compds. C. and S. present data on the absorption spectra of the normal and isodiazotates and the corresponding nitrosophenylhydroxylamine and phenylnitroamine. Data are also presented on the absorption spectra of the *p*-Cl and *p*-Br derivs. of the above. All of the curves obtained are similar in character; the normal diazotate and aryl-nitrosophydroxylamine have less absorption than the isodiazotate and phenylnitroamine. The data agree with the theory of Angeli that these compds. are structural isomers and not stereoisomers as Hantzsch describes them.

WALLACE R. BRODE

The absorption spectra and constitution of azoxy compounds. L. SZEGÖ. Univ. di Milano. *Ber.* 61, 2087-91(1928).—The theories described in the preceding abstract are applied to Br, NO₂ and OH derivatives of azoxy benzene. S. assumes the presence of a tervalent and a quinquivalent N in the compd. The α and β forms give nearly identical absorption spectra, only the di-substituted derivatives in the α form showing an additional band in the far ultra-violet. S. explains the failure of the mono-substituted isomers to show different absorption on the basis that the mono-substituted halogen or nitro on the benzene nucleus is without influence on the optical properties of the compd.

WALLACE R. BRODE

Ultra-violet absorption spectra of several benzene derivatives. F. W. KLINGSTEDT. *Z. physik. Chem., Abt. B*, 1, 74-93(1928).—The absorption spectra of acetanilide in pentane, in hexane, and in EtOH and of aniline in hexane, and of benzene in hexane were detd. Acetanilide in hydrocarbons shows 2 regions of selective absorption between 2900 and 2630 A. U. as do several other benzene derivs. The phenyl radical seems to be characteristic of such behavior, since other mono-substitution products behave likewise. In alc. soln. a different activity is revealed in the disappearance of the minor absorption regions. Aniline has a very different spectrum from that of acetanilide, the presence of the acetyl group causing a change in selective absorption toward shorter wave lengths.

WILLIAM E. VAUGHAN

The ultra-violet absorption bands of oxygen. A. S. GANESAN. *Indian J. Physics* 3, 95-104(1928).—The paper deals with the structure of the 5 ultra-violet absorption bands of O₂, $\lambda\lambda = 1946-1953, 1923-1934, 1902-1920, 1882-1897$ and $1864-1878$. The lines in the bands are given by the well-known relation of the type $\nu = A + 2Bm + Cm^2$. The band-heads are given by $\nu_0 = 49,350 + 708n - 13n^2$, where n has values from 3 to 7.

G. CALINGAERT

Kinetics of the action of iodine on potassium nitrite in the dark and in the light. A. BERTHOUD AND W. E. BERGER. *J. chim. phys.* 25, 542-61(1928).—See C. A. 22, 2112.

E. H.

A study of the Raman effect in glycerol and glycerol-water mixtures. S. VENKATESWARAN. Government Test House, Alipur. *Indian J. Physics* 3, 105-22(1928); cf. C. V. Raman, C. A. 22, 2707, 2884.—The paper gives the results of investigations on the modified radiations produced in glycerol when light from a

quartz Hg lamp is diffused through the liquid. The spectrogram of the scattered light contains a bright continuous spectrum and a no. of modified lines including one of enhanced frequency. The modified lines present in the scattered spectrum have been measured and analyzed, and the frequency differences between the modified and unmodified lines have been calcd. The shift of frequency of the modified lines corresponds to certain characteristic infra-red frequencies of the mol. The wave lengths corresponding to these have been compared with the values of the maxima obtained by Pfund in his reflection measurements of glycerol. It is shown that the method of detg. these natural frequencies from the spectrum of the modified radiations is far more convenient and accurate than reflection measurements. The values for the depolarization of glycerol scattering with white sun light as the incident radiation and with different filters in the path of the incident light are given. The depolarization factor is found to be practically independent of the wave length of the incident light. With the help of suitable filters the modified and unmodified parts of the scattered light were isolated and their polarization was measured. It is shown that the scattered light consists mainly of the continuous spectrum and that the degree of polarization of the modified and unmodified parts are of the same order. These have been confirmed by spectroscopic observations. The origin of the continuous spectrum is discussed. The effect is observed in many liquids even after the most careful purification, suggesting that it is characteristic of the chem. nature of the liquid. The strong continuous spectrum observed in glycerol is definitely shown to be characteristic of the pure liquid. Expts. are described to find the relation between the continuous spectrum and the viscosity of glycerol. The intensity of the continuous spectrum falls off rapidly at high temps. although the classical scattering increases with temp. There is a slight diminution of the intensity of the modified lines with increase in temp., suggesting that these are incoherent. The effect of diln. has also been studied and it is shown that the intensity of the continuous spectrum diminishes on diln. These suggest that the presence of the continuous spectrum in glycerol is intimately connected with its high viscosity. There appears to be some interrelation between the continuous spectrum and the modified lines. The intensity of the former shows a discontinuity, brightening up on the longer-wave-length side after every modified line. A similar relation exists between the characteristic frequency of the mol. and the continuous spectrum in liquids where the latter effect is due to impurities. The importance of this relation to fluorescence is indicated.

G. CALINGAERT

Raman effect in gases and vapors. L. A. RAMDAS. *Indian J. Physics* 3, 131-6 (1928); cf. C. V. Raman, *C. A.* 22, 2707, 2884.—By means of a specially constructed spectrograph of very large light-gathering power, the Raman effect was successfully photographed with Et_2O , vapor and liquid, at room temp. The change of wave length in scattering is found to be the same in the vapor and the liquid, within the limits of exptl. error. The intensity of the radiations of modified frequency in relation to that of original frequency is smaller in vapors than in liquids. This is accounted for by measurements of the intensity of the modified radiation, which show it to be roughly proportional to the density of the fluid while that of the radiations scattered without change of frequency is much less in liquids than in proportion to the density. Some observations on the modified scattering in CO_2 liquid and vapor at and near the crit. temp. are also described.

G. CALINGAERT

The Raman spectra of scattered radiation. R. W. WOOD. *Johns Hopkins Univ. Phil. Mag.* [7], 6, 729-43 (1928).—W. obtains Raman spectra with CCl_4 , CHCl_3 , C_6H_6 , quartz and calcite and compares them with the near infra-red spectra of these substances.

GEORGE GLOCKLER

The Raman effect in crystals. I. RAMAKRISHNA RAO. Bihar National College, Bankipore. *Indian J. Physics* 3, 123-9 (1928).—In this paper, the effect discovered and explained by C. V. Raman of the change of wave length which occurs when light is scattered in fluid and solid media has been studied in cryst. ice and quartz. The difference between the incident and scattered frequencies corresponds to the characteristic infra-red frequencies of the crystals. Compared with the case of water, the bands observed with ice are sharper and of shorter wave length. This agrees with the infra-red absorption data.

G. CALINGAERT

Dispersion of light in crystals. G. LANDSBERG AND L. MANDELSTAM. *Inst. for Theor. Physics, Moscow Univ. Z. Physik* 50, 769-80 (1928).—L. and M. permit light from a Hg lamp to fall upon quartz and calcspar and find that every spectral line of the incident light corresponds not only to a line of the same frequency in the dispersed light which they term the fundamental line, but it also corresponds to a no. of satellites. The wave lengths and intensities of the satellites have a definite regular

relation to the fundamental lines. L. and M. used a 110-v. Heraeus Hg lamp consuming 70 v. and 3 amp. and a Fuess, Model B, quartz spectrograph with Ilford, Iso-Zenith and Monarch plates. The image was developed with hydroquinone for 6 mins. in total darkness. A Hilger comparator was used to measure the spectrogram and Hartmann's interpolation formulas were used to calc. the wave length. Five systems of satellites were found for quartz and 2 for calcspar. For every system of satellites the difference, $\Delta\nu_i$, between the frequency of the satellites and the corresponding fundamental line is a const. for all fundamental lines. This indicates that for every satellite system $\Delta\nu_i$ corresponds to a definite crystal frequency. For corresponding wave lengths the values found are, for quartz, $\lambda_1 = 21.5\mu$; $\lambda_2 = 48\mu$; $\lambda_3 = 81\mu$; $\lambda_4 = 13.5\mu$, $\lambda_5 = 9\mu$ for calcspar, $\lambda_1 = 9.1\mu$; $\lambda_2 = 34\mu$. The connection between the characteristic frequency detd. and the infra-red frequency of the crystals is discussed. The intensity of the violet satellites increases with rising temp. as compared with the intensities of the red satellites.

S. L. B. ETHEKTON

The scattering of light by particles of metallic oxides dispersed in dry air. T. C. NUGENT AND H. P. WALMSLEY. *Proc. Phys. Soc. (London)* **40**, 269-80(1928).—An examn. has been made of the time changes in the brightness of the Tyndall-light from ZnO, CuO CdO and As₂O₃ clouds. These changes indicate a gradual decrease in the no. of particles per unit vol. which must be due to loss by aggregation or sedimentation. A series of clouds vaporized from various masses (m) of As₂O₃ were obtained in which the brightness of the Tyndall-beam was approx. proportional to $m^{3/2}$. The actual fluctuations in brightness occur in groups, the times of occurrence of a large no. of the minima being represented by the formula $T = Ar^n$, where n is an integer and A and r are consts.

FRANK V. JOHNSON, JR.

Variations in the fine structure of H α . G. H. HARRISON. *Proc. Phys. Soc. (London)* **40**, 300-6(1928).—A study was made of the intensity changes in the fine-structure components of the Balmer lines of H, taking place at fixed pressures and current densities, with alteration of the bore of the discharge tube. Variations in the intensity ratio taking place with tube bore or gas pressure, which in the present expts. reach 100%, may be attributed to the changes of the elec. field surrounding an emitting particle. The mean value of 0.304 cm.⁻¹ for the doublet sepn, remained practically const. throughout the expt.

FRANK V. JOHNSON, JR.

A method for determining the Kerr constant of a poorly insulating substance with the help of an electric alternating field. WALDEMAR ILBERG. *Univ. Leipzig. Physik. Z.* **29**, 670-6(1928).—The Kerr const. of nitrobenzene is detd. The value varies from 31.1×10^{-6} for a wave length of 467 to 20.2×10^{-6} for a wave length of 639. The measured values are in good agreement with those calcd. from the Havelock formula.

MARIE FARNSWORTH

The falling off of the after-glow in air. MARIA MAJEWSKA. *Z. Physik* **50**, 372-84(1928).—After stopping the elec. discharge in a vacuum tube contg. air at about 1 mm. pressure a yellowish green luminescence persists and extends beyond the region of discharge. This after-glow was obtained in a glass tube connected to the discharge tube and photographed up to a distance of 1.5 m. The logarithm of the intensity of the luminescence decreased linearly with the distance from the discharge line, showing that the relation is exponential. On the assumption that a definite chem. reaction is responsible for the excitation of the after-glow in air, the observed results can be explained only by a monomolecular reaction.

E. R. SMITH

Life period of excited mercury atoms. T. ASADA. Kaiser Wilhelm Inst. *Physik. Z.* **29**, 708-10(1928); cf. *C. A.* **22**, 4369. —A. has shown that the "stepwise" fluorescence of Hg vapor, discovered by Fuchbauer, can also be obtained in a resonance vessel contg. N which is far away from the stimulating Hg lamp. The long life period of the metastable Hg atoms in the $3P_0$ state which are obtained by the collision of the previously excited $3P_1$ atoms with N mols. may be easily demonstrated by the app. indicated. The brightness of the visible fluorescence is not induced by the momentary illumination with the Hg lamp but grows with illumination. From photographic-photometric measurements of the brightness of fluorescence as a function of the speed of rotation of the disk in the app. described, the dependence can be quantitatively followed and it is found that at a pressure of several mm. the av. life period of the $3P_0$ atoms is about 10^{-3} sec. The length of life depends on the purity and the freshness of the N, for H, etc., destroy the excited atoms. The above value was obtained with N freshly made from Na azide. Excited violet light also annihilates the $3P_0$ state. A brief description and use of the app. is given together with errata and explanations of work published previously.

S. L. B. ETHEKTON

X-ray phosphorescent and thermophosphorescent radiations of kunzite. OTTO

STUHLMAN, JR., AND A. F. DANIEL. *J. Opticql Soc. Am.* 17, 289-94(1928).—The spectral distribution of the phosphorescence excited in kunzite crystals by general x-radiation was detd. The color of the light led to the suspicion that the emission possessed the same spectral distribution as the cathode phosphorescence of kunzite described by Nichols and Howes and Ra-excited phosphorescence described by Lind and Bardwell. A Coolidge tube operated at 50,000 v. and 20 milliamp. was used to radiate samples of kunzite. Visual examn. showed a strong orange-red and a blue-green band. A pale lilac crystal radiated gave the usual shades. At 168° a rose-colored light was emitted. The bands widened up to 400°, at which temp. the phosphorescence ceased. At room temp. the blue-green color had disappeared. Radiation built up the color again. Heating does not drive off water of crystn. Luminescent radiations of kunzite are independent of the method by which they are produced and depend only on the reaction between the solvent and solute taking part in the chem. reaction with the emission of chemiluminescent radiations. L. D. ROBERTS

Spectra of calcium sulfide-strontium sulfide samarium mixed phosphors. Remark on the work by M. Travnicek. ERICH RUMPF. *Ann. Physik* 84, 840(1928); cf. *C. A.* 22, 728.—The actual compn. of the CaS-SrS-Sm phosphorescent grains in a sample was detd. from the grating const. taken by the Debye-Scherrer method. According to the percentage concn. the wave length of the red band should have been, on Travnicek curve, 6056.0 A. U. It was actually 6057.8. This confirms the possibility suggested by Travnicek of estg. the actual compn. of mixed phosphors from the position of the phosphorescence bands. A. L. HENNE

Luminous carborundum detector and detection effect and oscillations with crystals. O. V. LOSSEV. Nijny-Novgorod. *Phil. Mag.* [7], 6, 1024-44(1928).—Observations are described of the phenomenon of luminescence produced at the contact of a carborundum detector. The view is held that the luminescence is the consequence of a process at the contact which is very similar to cold electronic discharge. G. G.

Ultra-violet fluorescence of iodine bromide vapor. A. FILIPPOV. Optical State Inst., Leningrad. *Z. Physik* 50, 861-73(1928).—F. investigates the ultra-violet fluorescence of the vapors of Br₂, IBr, ICl and also the mixts. I₂ + N₂, IBr + N₂ and ICl + N₂. The gases were activated by light from the sparks of a large induction coil in an arrangement described. Br gave neg. results but IBr gas gave a violet light on activation with sparks from Al. The following bands were found: 2890, 2915, 2935, 2960, 2995, 3015, 3050, 3125, 3160, 3205, 3265, 3325, 3400, 3500, 3650, 3705, 3770, 3855, 4055, 4160, 4210, 4364, 4495, 4675 and 4850 A. U. Bands between 1850 and 2200 A. U. were found by photographing on oil-sensitized plates but no values were obtained in this region. N₂ added to IBr or I₂ vapor has a considerable effect on the fluorescence, changing the violet of IBr to blue and the violet of I to deep green. Bands are obtained which split into a no. of single bands and remain up to atm. pressure. Conclusion: The ultra-violet emission of IBr vapor is due to activation of the IBr mol. The Br₂ band at the edge of 2930 A. U. splits like the 3460 of I₂ into a no. of single bands. S. L. B. ETHERTON

Fluorescence and photochemical changes. KRISHNA GOPAL MATHUR AND S. S. BHATTNAGAR. Univ. of the Punjab, Lahore. *Indian J. Physics* 3, 37-51(1928).—Solns. of quinine sulfate eosin, uranine, acriflavine and erythrosin were exposed to sunlight (a) and their fluorescences, absorption spectra and n_D measured accurately before and after exposure. The expts. were repeated (b) with gelatin present in the soln., (c) with NaOH present and (d) in sealed tube in the absence of air. Sunlight exposure in (a), (b) and (c) decomposes these substances as evidenced by a decrease in fluorescence and a change in absorption spectrum and index of refraction. The decompn. is less in (b) and (c) than in (a). In (d) no decompn. takes place. The photo-decompn. of fluorescent dyes and their subsequent transformation into non-fluorescent compds. are probably an oxidation phenomenon, which may have nothing to do with fluorescence. G. CALINGAERT

Influence of variation of the incident energy upon the velocity of several photochemical reactions. A. K. BHATTACHARYA AND N. R. DHAR. Allahabad Univ., India. *Z. anorg. allgem. Chem.* 175, 357-66(1928); cf. *C. A.* 22, 2111.—Several new photochemical reactions, (1) decompn. of aq. solns. of Na₂Co(NO₃)₆, (2) decompn. of aq. solns. of K₂S₂O₈, (3) K₂S₂O₈ + KI, (4) Br₂ + CH₃OH, (5) Br₂ + C₂H₅OH, (6) oxalic and chromic acids, (7) acetone and I₂ in aq. HCl solns., (8) lactic acid and KMnO₄ in presence of MnSO₄, and (9) tartaric acid and KMnO₄ in presence of MnSO₄, have been studied under the radiation both from a 1000-w. lamp and from the sun. The intensity of the incident energy was assumed to be proportional to the size of the opening into the reaction cell. Corrections for thermal effects are made. With the exceptions

of reactions (6) and (3) which had reaction rates proportional to the light intensity, all of the observed velocities were fairly comparable to the square root of the incident radiation d . Comprehensive exptl. data and theoretical explanations are given.

W. E. VAUGHAN

Action of the electric effluvia on the gaseous mixture sulfur dioxide and oxygen. J. MAISIN. Univ. Louvain. *Bull. soc. chim. Belg.* 37, 326-33(1928).—Berthelot's expts. on the effect of the non-disruptive electric discharge on a mixt. of SO_2 and O_2 have been repeated and completed. Contrary to Berthelot's results, but in accordance with Meyer (*C. A.* 17, 35) S_2O_7 is not formed. S_2O_{11} was found, which seems to be a definite compd., in contradistinction with Meyer who regards it as a mixt. of 2 different anhydrides.

Process for the treatment of ilmenite for the recovery of electrolytic iron and titanium oxide concentrate for pigment and other purposes. R. J. TRAILL AND W. R. McCLELLAND. *Can. Dept. Mines, Mines Branch No.* 688, 96-101(1928); cf. *C. A.* 21, 724.—In this preliminary study the results indicate the practicability of operating a plate cell at about 35 amp. per sq. ft., without causing undue Cl evolution at the anode, by arranging a rapid flow of electrolyte through the catholytic compartment of the cell. Process for the hydrometallurgical treatment of high iron-copper sulfide concentrates. Recovery of iron by electrolysis, copper as cement copper, and sulfur by distillation. *Ibid.* 101 9.—The main topics are leaching with residue retreatment, leaching with excess FeCl_3 and leaching with roast residue, single roast and single leach method. Roasting must be had at some stage in the process. This applies particularly to chalcopyrite-pyrite mixts. Further work is in progress.

L. W. RIGGS

The electrolytic zinc plant of the Sullivan Mining Co. ELLERY R. FOSDICK. *J. Am. Inst. Elec. Eng.* 77, 808-11(1928); *Elec. West* 61, 315(1928).—The present capacity is 50 tons per day. Provision has been made for additional units to increase the capacity to 150 tons per day. The Tainton-Pring process is used (*C. A.* 12, 253). The electrolyte enters the cells with 20% Zn and 22% H_2SO_4 and leaves for use in leaching with 2% Zn and 28% H_2SO_4 . Each cell contains 10 cathodes and 20 anodes. A unit consists of 150 cells in series. The cathode c. d. is about 11.1 amps. per sq. dm. This is automatically adjusted to keep the power input const. The current efficiency averages 85% and the energy efficiency 60%. Motor-generator sets supply electrolysis energy; their efficiency is 91%, including transformer losses.

B. M.

The anodic behavior of copper-antimony alloys. HANS NEUMARK. *Metall u. Erz* 24, 305-11; *Chem. Zentr.* 1927, 11, 1394.—The expts. were carried out to find a

way of working up Cu ores contg. Sb. In the electrolytical sepn., a current-impermeable film of Sb oxides soon appeared at the anode, which was the main obstacle in this process. In tartaric acid soln., this formation did not take place; but at a c. d. of 0.006 amp./sq. cm., a disturbance occurred on account of formation of an impermeable film of Cu tartrate. In the expts. with H_2SO_4 solns. of different concns., Sb oxide was formed at 0.08 amp./sq. cm., independent of the H_2SO_4 concn. Expts. with H_2SO_4 -tartaric acid mixts. showed that with 0.1 N H_2SO_4 + 0.1 N tartaric acid (1:1), only 0.05 amp./sq. cm. were attainable; with N H_2SO_4 + N tartaric acid (1:1), it was found that up to 0.15 amp./sq. cm., the voltage and current intensity increase continuously, then they decrease on account of the film formed. In these expts., Cu was deposited at the cathode as a spongy ppt. In a soln. of 0.5 N CuSO_4 + 0.5 N H_2SO_4 (1:1) at 0.054 amp./sq. cm., the potential started to rise and the c. d. to decrease on account of the anodic layer. The expts. showed that at 0.06 amp./sq. cm., a continuous electrolysis with well adhering Cu deposit at the cathode and without Sb entering the bath liquid, is possible. In 10% $\text{Cu}(\text{NO}_3)_2$ soln., the reaction takes its normal course up to 0.49 amp./sq. cm.; the oxide formed drops from the cathode as a dark gray ppt. Contrary to the sulfate electrolyte, not the least decline of the current or of the difference of potential could be observed. No Sb or nitrite was found in the electrolyte. Continuous tests at 0.09 amp./sq. cm. confirmed the favorable result with the nitrate electrolyte. In mixts. of N CuSO_4 + N $\text{Cu}(\text{NO}_3)_2$ up to 0.08 amp./sq. cm., the same result was obtained as in pure nitrate soln., but an increase of potential occurred. Expts. in HClO_4 soln. has a result similar to those in H_2SO_4 soln. Examn. of the polished surface of the alloy employed in these tests showed besides mixed crystals also free Cu dendrites. Expts. were made with an alloy of 57.3% Cu and 42.6% Sb. Examn. of the polished surface showed mixed crystals only. N. examd. the conditions in N and 0.5 N tartaric acid, N H_2SO_4 + tartaric acid soln., and CuSO_4 soln. In the tests with CuSO_4 - $\text{Cu}(\text{NO}_3)_2$ mixts., the optimum mixt. was 1:1; the current efficiency was 76% for Cu and 22% for Sb, together 98%. Further expts. with $\text{Cu}(\text{ClO}_4)_2$, N HClO_4 and $\text{Cu}(\text{ClO}_3)_2$ showed that a continuous electrolysis at any c. d. is only possible in nitrate, chlorate and nitrate-sulfate soln. For the technical use, only the nitrate and nitrate-sulfate soln. can be considered; the tartaric acid- H_2SO_4 method, which is feasible at low c. d., has to be eliminated because of Sb being deposited together with the Cu at the cathode. In expts. with a technical alloy contg. 63.3% Cu, 13% Sb, 9.6% Pb, 4.7% Sn, 1.8% As, 2.7% S, 0.34% Fe, 0.03% Ag, in $\text{Cu}(\text{NO}_3)_2$ soln., pure Cu was deposited at the cathode, and the potential stayed const. up to 0.21 amp./sq. cm. Pb, but not Sb or Sn, could be detected in the electrolyte. In expts. with mixts. of $\text{Cu}(\text{NO}_3)_2$ and CuSO_4 , out of 50 cc. N $\text{Cu}(\text{NO}_3)_2$ + 40 cc. N CuSO_4 + 10 cc. N H_2SO_4 , within 72 hrs. at an anodic c. d. of 0.01 amp./sq. cm. and a cathodic c. d. of 0.004 amp./sq. cm., a firmly adhering deposit of cryst. Cu was obtained; the current efficiency was 97% of the Cu value given by the coulometer. The Cu loss of the electrolyte was 11% of the Cu deposited. The anodic current efficiency for Cu was 86%. Therefore, the nitrate-sulfate electrolyte is the most suitable one for obtaining a technically pure Cu with good current efficiency. G. SCHWOCH

Studies on electroplating. (Second series.) Electrodeposition on aluminum. III. The non-adhesion of electrodeposits. W. F. HUGHES. *Metal Ind.* (London) 33, 293-6(1928).—See C. A. 22, 4384. BENJAMIN MILLER

Protective effects of metal deposits on iron. S. The establishment of a *standard accelerated corrosion test* is recommended. BENJAMIN MILLER

High-voltage arcing and alternating current electrolysis. J. W. SHIPLEY AND CHAS. F. GOODEVE. Chem. Dept. Univ. of Manitoba. *Trans. Roy. Soc.* III [3], 22, 87-102(1928); cf. C. A. 21, 860, 1597.—The decompn. of water into H_2 and O_2 by high-voltage arcing on Fe electrodes was investigated for a. c. at voltages between 110 and 4200. The max. rate of gas evolution for electrodes of 0.203 cm. diam. was 266 cc. per min., representing a value of 826% of that calcd. for the same current from Faraday's law. The gas contained 65% H_2 and 30.6% O_2 by vol. For electrodes of 0.062 cm. diam. the rate of gas evolution of the same approx. compn. represents a value 1350% of that calcd. for the same current by Faraday's law. The cond. of the water was raised by adding NaOH. At const. c. d. the rate of decompn. of the H_2O due to arcing increased as the surface of the electrode increased. The current at which arcing commenced increased as the diam. of the electrodes increased, while the c. d. at which arcing commenced decreased as the surface of the electrodes increased. At high voltages arcing commenced at a definite point, varying inversely as the potential between

the electrodes. The rate of gas evolution was found to depend primarily on the rate of consumption of elec. energy and the decompn. is mainly due to thermal decompn. of the H_2O at the high temps. produced in the arc. Application of external pressure suppressed the arc; 3 lb. pressure above atm. suppressed the arcing at 700 v. whereas 31 lbs. was required to suppress it at 2200 v. Because of the explosion hazard connected with accumulations of H_2 and O_2 , elec. boilers should operate under sufficient external pressure to prevent arcing in the electrode chamber. The hot water would be conducted into a second lower pressure chamber and there permitted to boil.

J. W. SHIPLEY

Ballistic galvanometer method of potentiometric measurement for high resistance cells. H. T. BEANS AND GEORGE H. WALDEN, JR. Columbia Univ., New York City. *J. Am. Chem. Soc.* 50, 2673-8(1928).—A semi-deflection method of potentiometric measurement for cells having internal resistances as high as 50 megohms is described and the necessary precautions are pointed out. With cell resistances as high as 10 megohms, a precision of ± 0.1 mv is possible when all precautions are taken, and with cell resistance of 50 megohms a precision of ± 0.5 mv is possible. JAMES M. BELL

Wood separators for lead storage batteries. C. A. ROBAK. *Ind. Eng. Chem.* 20, 1151-2(1928).—The mechanical strength of smooth wood separators in contact with positive plates of lead storage batteries deteriorates more than that of separators in contact with negative plates, but the difference is not great enough to be a controlling factor in design. BENJAMIN MILLER

Effect of hydrogen-ion concentration on the voltage of the Leclanche dry cell. BERTHEL M. THOMPSON. *Ind. Eng. Chem.* 20, 1176-8(1928).—The voltage of a mixt. of MnO_2 and graphite is a linear function of the p_H of the soln. with which it is in contact. The p_H of the soln. must be measured after it has come to equil., since it is changed by contact with the electrode. The slope is -0.07 rather than -0.059 (the theoretical value) in the case of natural MnO_2 . With artificial MnO_2 the slope is -0.10 . The discrepancies are attributed to impurities. The method of prepg. the artificial MnO_2 is not given. No explanation is offered for the greater discrepancy in the case of the artificial material. BENJAMIN MILLER

The electrochemical reduction of azo dyes to their respective amino compounds. LEO P. HURBUCH WITH ALEXANDER LOWY. *Trans. Am. Electrochem. Soc.* 55, (preprint) 13 pp.(1929).—Six azo dyes, methyl orange, Metanil Yellow, Acid Scarlet, Crimson, Congo red and Fast Brown O, representing 6 different types, were reduced electrochemically to their resp. amino compds. in a Na_2CO_3 soln., at a Hg cathode. In general, the conditions found favorable for this reduction were a temp. of 95° , a c. d. of 0.885 amp./sq. dm., and a concn. of 7.5 g. of dye per 200 cc. of soln. It is shown that azo dyes, without an amino or a hydroxyl group in the *ortho* or *para* position to the azo group, can be reduced electrochemically in an alk. soln. to their corresponding amines. C. G. F.

The inventor of the Swan electric lamp. KENNETH SWAN. *Pharm. J.* 121, 425 6(1928).—The circumstances of the invention of the C filament lamp by Sir Joseph Swan and its demonstration, Dec. 1878, are recounted by his son. S. WALDBOTT

Storage battery and associated hydrometer device for indicating the density of the electrolyte. FRANK SCHWARTZ. U. S. 1,691,084, Nov. 13.

Storage battery with electrodes separated by glass wool. D. P. BATTERY CO., Ltd., B. M. DRAKE and J. WADDELL. Brit. 287,666, Jan. 19, 1927. Various structural features are specified. Cf. C. A. 22, 4389.

Storage battery electrodes. JOSEPH L. WOODBRIDGE. U. S. 1,691,794, Nov. 13. Two electrodes of sheet Pb with a thin wood veneer spacer between them are rolled into cylindrical form with the grain of the veneer substantially parallel with the axis of the cylinder.

Storage battery separators. NATHAN FALLEK. U. S. 1,690,573, Nov. 6. In forming separator plate elements, a pulp formed of wood fiber or other suitable vegetable fiber and water is boiled and washed to remove dirt and impurities, subjected to the direct action of steam, washed with a soda soln., rewashed to remove all traces of soda and then mixed with a small quantity of pulverized rubber and Na silicate and dried.

Controlling the level of electrolyte in storage batteries. SOCIÉTÉ DES ACCUMULATEURS ÉLECTRIQUES (Anciens établissements Alfred Dinin). Fr. 637,575, July 13, 1927. The covers of storage batteries are made of Pb contg. Sb and have projections on the lower face which form contact with the electrolyte and thereby close an elec. circuit which gives an audible or visible signal.

Apparatus for continuous casting of molten metal to form storage battery plates. JASPER N. DAVIS. U. S. 1,690,887, Nov. 6.

Apparatus (with an electric heater for the electrolyte) for electrodeposition of metals. W. Y. NEWLAND. Brit. 286,563, May 2, 1927.

Electrodeposition of chromium. FROHWALD WALTER WÜRKE. Ger. 467,025, June 28, 1925. Pure chromic acid to which a small quantity of the salts of the alk. earth or heavy metals, excepting Cr, has been added, is used as the electrolyte.

Electrodeposition of tin. SIEMENS & HALSKE A.-G. Brit. 286,673, March 8, 1927. Coherent Sn deposits are obtained from an alk. soln. which has been treated with an oxidizing agent (such as ozone, or H_2O_2 or an alkali metal or alk. earth metal peroxide) until practically all the Sn is present as stannate. Gelatin or other suitable colloid 1.5-10 g. per l. is added.

Electrodeposition of zinc. URLYN C. TANTON. Ger. 466,279, May 5, 1927. Manganiferous $ZnSO_4$ soln. is electrolyzed. A Pb anode, preferably free from Ag, Sn or As, is used and its surface is coated with a Pb-Ag alloy contg. at least $1/10$ Ag. Cf. C. A. 22, 2890.

Beryllium. KEMET LABORATORIES CO. Brit. 287,734, April 20, 1927. See Fr. 633,360 (C. A. 22, 3359).

Obtaining beryllium and other metals by electrolysis. KEMET LABORATORIES CO. Brit. 287,762, April 20, 1927. Metals are obtained by electrolysis of their halogen compds. in a fused halide electrolyte in a cell serving as cathode, the material of which contains at least 5% Cr. Nichrome or a Cr-Fe alloy contg. about 20% Cr is suitable.

Foraminius cathodes for electrolysis of alkali metal chloride solutions. A. ERGANG. Brit. 287,760, July 11, 1927. Structural features.

Electrolytic coatings of varying thickness. BERNDORFER METALLWARENFABRIK A. KRUPP A.-G. Brit. 287,402, Sept. 14, 1927. The electrolyte is applied to the un-submerged surface of the article being coated with metal, in the form of a jet, and the thickness of the deposited metal coating at different portions of the article is controlled by the strength, size and speed of the jet and the duration of its impingement.

Rotary apparatus for electroplating small articles. F. KIRSCHNER and J. HESS. Brit. 287,350, May 16, 1927.

Coppering. HJALMAR E. SUNDBERG. Fr. 637,525, July 12, 1927. In the electrodeposition of Cu from a bath contg. a halogen salt of univalent Cu, such as $CuCl$, one or more substances which increase the cathode potential by increasing the viscosity or forming diaphragms or by exercising an adsorbent or oscillating action on the cathode are added to the bath. Suitable compds. are compds. of other metals, carbohydrates, gelatin, peptone, org. amino compds., quinones, alkaloids or coloring substances; these substances may be added in the colloidal state. Cf. C. A. 22, 2116.

Nickel plating. AUGUSTO PASSALACQUA. Fr. 638,987, June 3, 1927. Metals,

particularly Al or its alloys, to be nickel plated are cleaned chemically and then immersed in a cold aq. bath contg. H_2SO_4 , NaHSO_4 , AlCl_3 , NH_4Cl , H_3BO_3 , alum and $\text{Al}_2(\text{SO}_4)_3$, then into a bath contg. CuCl_2 , H_2SO_4 and HCl and finally into a bath contg. NiSO_4 and NH_4Cl .

Coating articles with platinum and other metals. E. G. Bæk. Brit. 287,641, Dec. 24, 1926. In coating material of low m. p. with Pt as described in Brit. 244,487 (C. A. 21, 211), a Cd or Zn coating is first applied, a Pt coating is then applied and the materials are heated. Two or more layers of Pt may be applied with a heating after each application to produce a product of the desired color or an underlying coating of Au may be used. Red gold is made white by a deposit of Ni or green by a deposit of Cd or Ag with suitable heating. Yellow gold is made white by a deposit of Cr. Green gold is made red by suspending for a half min. in a warm alkali Cu bath, applying borax and heating to 500–550°.

Covering cable wires. FÉLIX KIRSCHNER and JOSEF HESS. Fr. 637,445, July 1, 1927. Metal cables and the like of Cu are protected against the action of S by a galvanic deposition of Sn, or a deposition of Sn followed by Zn and then Sn again, or a deposition of Ni or Cr followed by Zn.

Metal production in electric furnaces. EMIL G. T. GUSTAFSSON (to Hampus Gustaf Emrik Cornelius). U. S. 1,691,439, Nov. 13. In production of metals such as Fe or Fe alloys by practically continuous operation in an elec. furnace, a charge is smelted by elec. heat while forming metal and slag, the furnace is emptied to bare its bottom, a quantity of the slag is reintroduced in practically its original tapped condition for protection of the furnace bottom against the elec. arc, and charging for the next heat is then started.

Forming points or edges on metal blanks by electrolytic removal of metal. S. O. COWPER-COLES. Brit. 287,588, Sept. 27, 1927. An app. is described.

Iron and iron alloys by reduction of oxide ore. HENNING G. FLODIN and EMIL G. T. GUSTAFSSON (to Hampus Gustaf Emrik Cornelius). U. S. 1,691,274, Nov. 13. In order directly to produce dense Fe or Fe alloys from oxide ore contg. a metal such as V or Ti capable of deoxidizing and degasifying iron, from a charge of such ore, in finely divided condition, lime and charcoal or other suitable carbonaceous material, mixed and solidified, the charge is fed successively into an elec. furnace and smelted while floating on a slag bath in the furnace, iron and slag are sepd., an oxidizing slag is formed on the iron, the slag contg. the main part of the V or Ti is removed, and after slagging off, the slag from the oxidizing period is reduced in the presence of the refined Fe or Fe alloy in an elec. furnace and the Fe alloy is tapped.

Removing oxide or gases from metals. J. VON BOSSE. Brit. 286,632, March 7, 1927. Occluded gas is removed from metal deposited electrolytically on an object by mounting the latter as an electrode in an evacuated vessel and passing a discharge. Al may be thus deoxidized and it is also stated that a like process may be used for disintegrating waste rolled gold.

Non-magnetic alloy of high electric resistance. W. S. SMITH, H. J. GARNETT and J. A. HOLDEN. Brit. 287,236, Dec. 17, 1926. Fe 67–71, Ni 23–7, Cr 1.5–4 and Al or Si 1.5–4%, free from or low in C, with or without Mn about 1% or less.

Iron and iron alloys low in carbon. HENNING G. FLODIN and EMIL G. T. GUSTAFSSON (to Hampus Gustaf Emrik Cornelius). U. S. 1,691,273, Nov. 13. A charge of mixed and solidified Fe oxide ore and finely divided charcoal or other suitable carbonaceous material is reduced and melted in an elec. furnace in a non-oxidizing atm. Less reducing agent is used than that theoretically required for reduction of the ore, and the elec. cond. of the slag formed is decreased and metal of the metal oxides in the slag is liberated by adding a thermal reducing agent such as ferro-Si to the slag bath.

Metals and alloys low in carbon. GUSTAV H. FLODIN. U. S. 1,691,272, Nov. 13. Ore such as Fe and Cr ore is mixed with such a quantity of carbonaceous material such as charcoal as will substantially all be consumed on reduction, the mixt. is briquetted and the briquets are smelted in an elec. electrode furnace in which heat is developed by elec. resistance in the slag bath with the charge swimming on the slag. An app. is described. Lime may also be used in making the ore briquets.

Fused silica. QUARTZ ET SILICE. Fr. 639,006, Jan. 5, 1927. In the production of fused SiO_2 from sand packed round a C rod raised to a high temp. by an elec. current, an oxidizing atm. is maintained in the furnace by circulating air or O in the furnace, or preferably by adding a small quantity of water to the sand before it is introduced into the furnace.

Dielectric materials. A. JORRE. Brit. 286,747, Sept. 8, 1926. In producing dielectric layers of high resistance to leakage, as described in Brit. 257,060 an elec.

current is passed through the dielectric at a high temp. (suitably about 500°). Glass, mica, calcite, mother-of-pearl, Al₂O₃ and Al phosphate may be thus treated.

• **Dielectric materials.** A. JOFFE. Brit. 287,039, Sept. 8, 1926. In producing thin insulating layers of the type described in Brit. 257,080, having a high resistance to leakage and of a thickness less than 0.01 mm., a dielectric which reacts with O is suitably treated with air, O or ozone and Cl, e. g., linseed oil may be polymerized at 250° with a Co or Mn siccative.

Dielectric materials. S. BOYER (to British Thomson-Houston Co., Ltd.). Brit. 287,140, March 16, 1927. Materials (suitable for use in condensers or like app.) of high dielectric const., specific resistance and dielectric strength, such as PhNO₂, are mixed with another dielectric material such as nitrotoluene, to lower the f. p. and prevent any change in the dielectric character of the compn. when used at low temps. Other substances such as dinitrobenzene and PhCl may be added. Impurities in PhNO₂ such as water, acids or salts are removed by mixing Al₂O₃ with either ingredient, heating to 100° and distg. Structural features of a condenser made with the specified dielectrics are described.

Electrolytic rectifier. WALTER E. HOLLAND (to Philadelphia Storage Battery Co.). U. S. 1,691,806, Nov. 13. A non-film-forming electrode of an asymmetric cell is formed of Fe contg. at least 10% Si. This may be used with an electrolyte comprising H₃PO₄ or a phosphate, borate or carbonate and another electrode formed of Al. Various structural features are described.

Electrolytic rectifier. L. LEVY. Brit. 287,778, Aug. 24, 1927. In a device such as described in Brit. 265,652 comprising an Al-Cu contact with an intermediate layer of Cu sulfide, the latter is kept moist by liquid NH₄ hydrosulfide supplied by capillary action through a wick. Various structural details are described. Cf. C. I. 22, 2721.

Rectifier for alternating currents. J. SLEPIAN (to Metropolitan Vickers Electrical Co., Ltd.). Brit. 288,174, April 2, 1927. An effective elec. connection to a surface of poor cond. material such as the oxide coating in Cu oxide rectifiers is obtained by cementing to the surface a layer of finely divided cond. material such as graphite, by means of a solidified insulating material such as paraffin or a phenol condensation product. A Pb plate may be pressed onto the graphite coating and the condensation product may be solidified by heating.

Materials for rectifying alternating currents. SIEMENS SCHUCKERTWERKE A.-G. Brit. 288,151, March 31, 1927. Various means are specified for cooling the inner surfaces of annular elements of the Cu-Cu oxide type, by circulating liquid or gaseous cooling media through the app.

Electric discharge devices. ALLGEMEINE ELEKTRICITÄTS GES. (to International General Electric Co.). Brit. 287,138, March 16, 1927. Anodes or other parts are formed of an alloy of W or Mo, or both, with 0.5-1.0% of metals such as Al, Cr, Hf, Mn, Th, Ti, Zr, Ce or other rare earth metal, or Si, which are as readily or more readily vaporized than Mo.

Electric discharge devices. H. SUNDBERG. Brit. 287,883, March 28, 1927. A general method and app. are described relating to emission of electrons from metals or their compds. by heat and transmission of energy.

Electrode material of electric discharge devices. E. HARSANYI. Brit. 287,098, March 14, 1927. Refractory metals such as W, Mo or Ta, oxides such as alk. earths, Th or Ce oxides, or a mixt. of W and Ti, are deposited on a metal core connected as cathode, by electrophoresis from a colloidal dispersion. Electrolytic action is avoided by using a low voltage (suitably 2 v.), by using a depolarizer at the cathode, or by using an electrolyte which does not yield gaseous ions at the cathode. Numerous details are given.

Electrodes. PÖRSCKE ELEKTRICITÄTS-GESELLSCHAFT M. B. H. Fr. 637,746, July 15, 1927. Electrodes are made from metallic oxide or spongy metals, the surface of which is multiplied several times by artificially formed spaces through the mass.

Electrodes. METALLBANK UND METALLURGISCHE GES. Ger. 466,357, June 4, 1920. Deposits on emission electrodes are removed by scraping or rubbing.

Electrode holder and mantle for electric furnace electrodes which are baked while in use. MARTIN WALTHER (to Det. Norske Aktieselskab for Elektrokemisk Industri). U. S. 1,691,505, Nov. 13. Structural features.

Glowing cathodes. SIEMENS & HALSKE. A.-G. (Albert Lotz, inventor). Ger. 466,462, Dec. 18, 1924. A glowing filament of high m. p. is provided with a coating of Hf. The filament may be coated with a Hf compd., e. g., the oxide and reduced by an alkali metal.

Electric furnace. SIEMENS ELEKTROWARME-GESELLSCHAFT M. B. H. (Stephan

Schneider, inventor). *Ger. 466,502, May 24, 1925. In a salt-bath furnace 2 crucibles are used one inside the other, and the salt-bath-heating-substance is placed between them.

Electric furnaces. RENÉ DUFOUR. Fr. 638,801, Aug. 3, 1927. High-frequency induction furnaces are so constructed that the induction elements dip into or are surrounded by the material to be heated.

Electric furnaces. COMPAGNIE GÉNÉRALE D'ÉLECTRICITÉ. Fr. 637,601, Nov. 10, 1926. In an elec. resistance furnace the metallic heating wires or bands are placed directly in the atm. of the heated chamber.

Electric furnace for light metals. ALUMINIUM-INDUSTRIE AKT.-GES. Ger. 166,551, Jan. 6, 1926. Addn. to 456,806.

Electric furnace construction. GUIDO SAGRAMOŠO. U. S. 1,690,795, Nov. 6.

Electric arc furnace. JAMES C. WOODSON (to Westinghouse Elec. & Mfg. Co.). U. S. 1,691,365, Nov. 13.

High-frequency electric induction furnace for heat treatment of metal disks or other articles. GEORGE F. HARRINGTON and PORTER H. BRACE (to Westinghouse Elec. and Mfg. Co.). U. S. 1,691,349, Nov. 13.

Bright-annealing furnace heated by electric resistances. KARL TAMELE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,691,259, Nov. 13.

Electric resistance furnace. ALBERT J. HANSON (to American Metallurgical Corp.). U. S. 1,690,678, Nov. 6. Structural features.

Electric resistance furnace. FRANK T. COPE (to Electric Furnace Co.). U. S. 1,690,273, Nov. 6. Structural features.

Electric resistance furnace adapted for bright-annealing. KARL TAMELE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,691,258, Nov. 13.

Electric resistance materials. A HEKROWSKY (to Elektro-Heiz und Warme Ges.). Brit. 287,458, March 19, 1927. Resistances are formed from C such as graphite or gas coke, mixed with materials necessary for the formation of an oxide of Si, Ca or Al or the like, formed into a plastic material with a binder and pressed into filament form. The filaments are dried and elec. heated until the desired resistance is attained and may then be surrounded by a body of cast metal. Oxides of Zr, Th or U may be employed in the case of resistances which are to be used at high temps.

Oven heated by electric resistances. SOC. ÉTABLISSEMENTS SABLYET (to F. W. Tabby). Brit. 287,173, March 18, 1927. Structural features.

Apparatus for electrically heating metal articles. RICHARD E. BISSELL (to Thompson Products, Inc.). U. S. 1,691,562, Nov. 13.

Electrical conductor. FRANK F. FOWLE. U. S. 1,691,869, Nov. 13. Metal of high cond. such as a Cu wire is substantially enclosed in an Fe base metal such as surrounding steel wires which have relatively great mech. strength and contain at least 0.30% C. Cf. C. A. 22, 3592.

Loaded electrical conductor. ADOLPH F. BANDUR (to Western Electric Co.). U. S. 1,691,029, Nov. 13. A central conductor such as wrapped wire is provided with a coating of material such as mica which will act as a separator and which will not be consumed by heat treatment, a magnetic loading material such as a suitable alloy is wrapped around the conductor and the loading material is given the proper elec. characteristic by heat treatment.

Loaded electric conductor. WILLOUGHBY S. SMITH, HENRY J. GARNETT and JOHN A. HOLDEN. U. S. 1,691,309, Nov. 13. A metal spacer such as Ag-Cu alloy which is fusible at a temp. not exceeding the temp. for annealing the loading is laid upon a conductor such as Cu and loading material is wound over the spacing material; the assembled materials are then subjected to heat treatment which causes the metal spacer to melt. Cf. C. A. 22, 3592.

Electrical device for indicating the electrolyte specific gravity or condition in electric battery cells. EDGAR G. PETERS. U. S. 1,690,500, Nov. 6.

Electric accumulator with alkaline electrolyte. AXEL ESTELLE and PAUL HAGSPILL. Ger. 466,801, Apr. 8, 1926. An alk.-electrolyte accumulator of the type having O compds. of Ni and Co as the active mass of the pos. electrodes and twice as many pos. electrodes as neg. electrodes is constructed so that each pos. plate is resiliently supported against the neighboring pos. plate or against the wall of the accumulator.

Preventing and removing incrustation in boilers. G. S. NEELEY and G. WATKINS. Brit. 287,196, Nov. 12, 1926. An a. c. is applied to the feed water before it enters the boiler and another current of different phase and voltage to the shell of the boiler and water in the boiler. Various details of elec. connections are described. Cf. C. A. 22, 32.

Ozone. SIEMENS & HALSKE AKTIEN-GESELLSCHAFT. Fr. 637,503, July 12, 1927. In an app. for the production of ozone by high frequency, wherein the generator circuit is tuned to the frequency of the source of supply, a coreless transformer is used to produce the high tension necessary for the discharge. Cf. C. A. 22, 2518.

Ozone generators. ALBERT CHARBONNEAU. Fr. 638,991, Jan. 4, 1927. Two forms of generators are described: in one the electrodes are disks with metallic brushes and the connection between the oscillating circuit and the electrode circuit is made by induction by means of coils surrounding the discharge elements; in the other the discharge elements are made of metallic boxes forming one electrode and contg. the other.

Treating various materials with ozone. S. ACZEL. Brit. 287,904, March 29, 1927. Fibrous substances, fabrics, waxes, drugs, foods, candles, oils, etc., are treated with ozone by direct exposure to elec. discharges, by being placed between or around the electrodes. Cellulose may be converted into oxycellulose. An app. is described.

Pressure-actuated control for electric circuits. IRA E. McCABE. U. S. 1,690,689, Nov. 6.

Heat-exchange apparatus for electric transformer tanks, etc. BRITISH THOMSON-HOUSTON CO., LTD., AND R. DUMAS. Brit. 287,624, Dec. 22, 1926.

Pressure-responsive device for control of electric circuits. GLENN MUFFLY. U. S. 1,691,666, Nov. 13.

Apparatus for separating constituents of emulsified oils such as petroleum by electric treatment. CHARLES W. McKIBBEN. U. S. 1,691,578, Nov. 13.

Electric system for measuring the rate of flow and temperature of steam, gas, water or other fluids. CHARLES F. BRUSH, JR. and RICHARD D. FAY (to Brush Laboratories Co.). U. S. 1,691,600, Nov. 13.

Electric arc. ALLGEMEINE ELEKTRIZITÄTS-GESELLSCHAFT. Ger. 466,380, Oct. 10, 1925. An arrangement for regulating an elec. arc furnace is described.

Mercury vapor lamps. HANOVIA CHEMICAL & MANUFACTURING COMPANY. Fr. 638,802, Aug. 3, 1927. The arc tube is surrounded by an envelope of quartz contg. any desired gas, the whole being placed in a cooling vessel contg. water.

Mercury vapor lamp for the production of light or ultra-violet rays. HENRI GEORGE. Fr. 637,657, Nov. 18, 1926. A deformable body contg. gas or air under pressure is placed in the bulb filled by the Hg, and by its action on the level of the Hg in the bulb causes lighting of the arc.

Maintaining vacuums in vacuum tubes. CLARENCE W. BALKE (to Fansteel Products Co.). U. S. 1,691,177, Nov. 13. A piece of Cb is placed adjacent a filament so as to be heated by the filament and to absorb gases present in the tube.

Apparatus for evacuating electric bulbs and like vacuum vessels. NAAMLÖÖZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN (Johannes Marinus van der Poel, inventor). Ger. 466,639, May 8, 1926. Addn. to 427,354.

Electric arc lamp with connections for directing gas currents along the electrodes. Y. A. ROCARD and P. DE ROTHSCHILD. Brit. 287,160, March 17, 1927.

Electric incandescent lamps. NAAMLÖÖZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 287,563, March 25, 1927. A filling of substantially pure A may be used without risk of discharge occurring by placement of a screen of quartz, mica or glass between conductors or parts of the filament.

Electric incandescent lamps. B. ERBER. Brit. 286,687, March 9, 1927. Bulbs with filaments of Ta carbide or the like have a filling of inert gas to prevent decompn. of the carbide. The filaments may have a metal core and may be helical in form.

Double incandescent electric lamps. YUKITOSHI SAKAKURA. Ger. 466,638, Nov. 5, 1926. The inner lamp is made readily replaceable.

Apparatus for degassing incandescent lamp filaments and applying gettering material, etc. PATENT-TREUHAND-GES. FÜR ELEKTRISCHE GLÜHLAMPEN (to General Electric Co., Ltd.). Brit. 286,718, March 10, 1927.

5—PHOTOGRAPHY

C. E. K. MEES

Apparatus for liquid treatment of bands or strips, particularly cinematograph films (Ger. pat. 466,979) 1.

Photography. I. G. FARBENIND. A.-G. (Bruno Wendt, inventor). Ger. 467,179,

Jan. 8, 1927. The Ag salt is carried by an emulsion which does not form a compd. which increases sensitiveness when treated with S.

Photography. KALLÉ & Co. A.-G. (Maximilian Paul Schmidt and Wilhelm Krieger, inventors). Ger. 467,090, Sept. 7, 1927. Light-sensitive layers are prepd. by a mixt. of at least 2 diazo compds. having the same base. Thus, a film contg. a mixt. of the CdCl_2 double salt of 5-diethylamine-2-diazo-1-phenol and 4-chloro-2-diazophenol-6-sulfonic acid is used and gives an orange picture. Other examples are given.

Photography. G. KÖGEL. Ger. 467,089, July 8, 1926. The film contains a ketone sensitive to light and is developed with Ag salts or org. substances such as methyl-*p*-aminophenolsulfite.

Color photography. J. H. POWRIE. Brit. 287,388, Oct. 11, 1926. Mech. and optical features.

Color photography. RICHARD GSCHÖPF. Fr. 637,423, June 2, 1927. Ger. 467,091, May 21, 1927. See Brit. 279,381 (C. A. 22, 2891).

Optical system for color photography. SOC. CIVILE POUR L'ETUDE DE LA PHOTOGRAPHIE ET DE LA CINEMATOGRAPHIE EN COULEURS. Brit. 287,488, March 21, 1927.

Film for color cinematography. J. E. THORNTON. Brit. 286,568, Oct. 12, 1927. Mech. features.

Multi-color screen system for color photography. J. H. POWRIE. Brit. 287,188, Oct. 11, 1926.

Color absorption screen for use in photography. ADELBERT AMES, JR. U. S. 1,691,366, Nov. 13.

Color photographs. WERNER LANGGUTH and CHARLES HUMMEL. Fr. 637,392, July 9, 1927. See Brit. 274,129 (C. A. 22, 1918).

Photographic films. PAUL SCHLOCHOFF. Fr. 637,675, June 8, 1927. Photographic and like films are made resistant to heat or variations of temp. by treating them with a soln. contg. 250 parts of a transparent plastic substance dissolved in acetone, 150 of glacial AcOH , 300 of acetoacetic ester, 75 of oil of turpentine or benzine, 200 of dissolved gum lac and 25 of crude camphor.

Inscriptions on photographic film. I. G. FARBENIND. A.-G. Brit. 287,124, March 16, 1927. The rear of raw film is impressed with spacing markings by use of a soln. of coloring matter in a slowly evapg. solvent such as glycol acetate which penetrates into the film support. The soly. of the coloring substance may be increased by mixing solvents of different rapidities of evapn.

Cinematographic films. AUGUSTIN ALONSO and JEAN VALLET. Fr. 637,330, June 21, 1927. Films have their clarity improved and are rendered unflammable by applying thereto 4 layers. The first layer is composed of Spanish white, fish glue and boric acid; the second HF, glass powder and gelatin; the third Ag powder and Hg; the fourth Ag powder, Al powder and gelatin. The layers are deposited in the order indicated, each layer being allowed to dry. Water is used as solvent for the first, second and fourth layer, the third forming an amalgam is used as it is.

Photographic sensitive material. I. G. FARBENIND. A.-G. Brit. 286,736, March 10, 1927. A light-sensitive layer contg. a salt of 1,2-naphthoquinone-4-sulfonic acid, as described in Brit. 286,233 (C. A. 23, 49), is developed after exposure by use of an alk. soln. of a substance which contains an acid methylene or methyl group such as trinitrotoluene, acetoacetic ester, cyanacetamide, methyl-phenylpyrazolone and resorcinol. The developer may be incorporated in the sensitive material and the image produced by the action of NH_3 vapor. Different developers permit production of images in different colors.

Photographic diazotype process. KALLÉ & Co. A.-G. Brit. 287,063, March 11, 1927. In the process described in Brit. 280,593 (C. A. 22, 3361) the tone of the developed print is modified by treating it with a small quantity of moisture which may be applied as vapor or by use of a damp sponge. Examples are given for producing dark brown prints.

Photographic reversal process. I. G. FARBENIND. A.-G. Brit. 287,542, March 20, 1927. After exposure the film is subjected to a short development not exceeding a duration fixed for the particular film material, the image is then reversed by dissolving out the Ag image, clearing, exposing to light and redeveloping, and the density of the resulting positive image is reduced by use of a bath having a uniform action which may be prepd. from I, KI and an aq. soln. of thiocarbamide. This reducing bath may also be used for dissolving out the Ag image produced by the first development.

Composition for joining strips of motion-picture films. ORRO W. COOK (to Eastman Kodak Co.). U. S. 1,690,622, Nov. 6. In order to render the compn. visible under

light of wave lengths in the red and orange wave lengths of the spectrum (In dark room use), there is added to it a dye such as xylene blue or alphasaurine G which is absorptive of such wave lengths.

6—INORGANIC CHEMISTRY.

A. R. MIDDLETON

Report on the revision of the nomenclature in inorganic chemistry. M. DELAPINE. *Chimie et industrie* 20, 603-9(1928); cf. *C. A.* 22, 2117.—An account of the decisions reached to date by the French sub-committee of the committee appointed by the International Union of Pure and Applied Chemistry. A. PAPINEAU-COUTURE

Constitution of hydroxides and of hydrates. I. G. NATTA. Reale Politecnico di Milano. *Gazz. chim. ital.* 58, 344-58(1928).—X-ray examn. was chosen as the method for studying the constitution of compds. contg. combined water. A review of the literature shows that previous expts. on hydrates have been limited to the geometry of the cryst. structure and have not shown the coordination of the H_2O mols, their position in the lattice and their dimensions. With hydroxides, the dimensions of the OH ion and its behavior from the point of view of isomorphism and morphotropy have not been ascertained. The expts., complete data of which are tabulated and discussed, lead to certain general conclusions. Metallic oxides, the metals of which in the state of bivalent ions have a radius between 0.77 and 1.10 A. U., belong to the isomorphic class of rhombohedral hydroxides. $Zn(OH)_2$ does not belong to this class because the bivalent Zn ion has a radius less than 0.77 A. U. $Ca(OH)_2$, $Cd(OH)_2$, $Ni(OH)_2$, $Mg(OH)_2$, $Mn(OH)_2$, $Fe(OH)_2$ and $Co(OH)_2$ do, however, belong to this class. All these hydroxides belong to the holohedral class of the rhombohedral system (3 Di-3) and have an elementary orthorhombic cell defined by the coordinates of the atoms: $M^{++} = (0\ 0\ 0)$; $O^{--} = (\frac{1}{3}\ \frac{2}{3}\ u)$, $(\frac{2}{3}\ \frac{1}{3}\ -u)$. The parameter u depends upon the size of the metal ion, and increases from 0.25 to 0.28 with an increase in the latter from 0.77 to 1.06 A. U. The base of the elementary cell of the rhombohedral hydroxides increases regularly with increase in the radius of the metal ion, while there is only an ill-defined relation between c/a of crystals of the compn. MX_2 and the ratio R_z/R_m of the component ions. From the distance O-M can be calcd. for O a radius between 1.33 and 1.38 A. U., a value which conforms to that detd. in another way for the bivalent O ion. The half distance O-O is about 10% greater than this value. Since the O ion is but slightly deformable, it may be assumed that the H ions which would occupy the positions $(\frac{1}{3}\ \frac{2}{3}\ v)$ and $(\frac{2}{3}\ \frac{1}{3}\ -v)$ impede the tangency of the O atoms. By assuming the spherical form of the O and H ions, calcs. show a radius of action of 0.3-0.4 A. U. If the OH is considered as an individual entity in the lattice, it should be limited by a non-spherical surface and should have a radius varying from 1.35 to 1.50 in 2 opposite directions. The OH would therefore have the form of a highly deformable ion similar to that of polarizable ions, such as I, and accordingly would form "stratified" lattices typical of compds. of polarized ions. C. C. D.

The crystalline alumina hydrate of v. Bonsdorff. R. FRICKE. *Z. anorg. allgem. Chem.* 175, 249-56(1928).—Alumina which ppts from solns of alkali aluminates by hydrolysis or slow interaction with CO_2 gives an x-ray spectrogram which is identical with that of the mineral hydrargillit (gibbsit) provided the sepn. takes place very slowly. Otherwise a different crystalline hydrate of the compn. $Al_2O_3 \cdot 3H_2O$ results, which is identical in its structure with that obtained in the prepn. of pure alumina from bauxite according to the method of Bayer. The designation Bayerite is proposed for the latter type of alumina. EMIL KLARMANN

Action of ammonia on alkali chromic chlorides. Chromamines which contain more than six molecules of ammonia. FRITZ EPHRAIM AND WILFRIED RITTER. Univ. Bern. *Helv. Chim. Acta* 11, 848-64(1928); cf. *C. A.* 19, 3070.—Several chromamines

	(max. not reached)		$[Cr(Co(NH_3)_2)_6]Cl_3$	0	8
$[Cr(NH_3)_6H_2O]Cl_3$	1	7.5	$[Cr(Co(NH_3)_2)_6]Br_3$	—	12
$[Cr(NH_3)_6H_2O]Br_3$	3	12	$[Cr(Co(NH_3)_2)_6]I_3$	—	12

were tested as to their behavior toward NH_3 at low temps. (ice-NaCl freezing mixt.). The loss of NH_3 by these compds. when heated was studied. The following compds. added no NH_3 either at room temp. or at low temps.: $[\text{Cr}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2$, $[\text{Cr}(\text{NH}_3)_5\text{Br}]\text{Br}_2$, $[\text{Cr}(\text{NH}_3)_5\text{CNS}](\text{NO}_3)_2$, $[\text{Cr}(\text{NH}_3)_5\text{CNS}]\text{Br}_2$, $[\text{Cr}(\text{NH}_3)_5\text{C}_2\text{O}_4]\text{NO}_3$, $[\text{Cr}(\text{NH}_3)_5\text{OH}]\text{Cl}_2$. A new method for the prepn. of roseo and purpureo chromammines is given.

LOUISE KELLEY

The action of mercury salts on iron pentacarbonyl. H. HOCK AND H. STUHLMANN. *Ber.* 61B, 2097-2101(1928).—The action of nitrate, sulfate, acetate, cyanide and halides of mercury on iron pentacarbonyl has been studied. HgCl_2 is reduced to Hg_2Cl_2 with the simultaneous formation of CO_2 and HCl . A momentary formation of $\text{Hg}_2\text{Cl}_2\text{Fe}(\text{CO})_4$ is also noted. In acetone solns., an unstable mol. compd., $\text{Fe}(\text{CO})_5\cdot\text{HgCl}_2$, is formed. This reacts with HgCl_2 to give the tetracarbonyl compd. noted in water and COCl_2 . In EtOH solns. the reaction seems to proceed as in water. The compd., $\text{Hg}_2\text{Cl}_2\text{Fe}(\text{CO})_4$, crystallizes in small monoclinic forms. It is insol. in most solvents, and is decomposed rapidly by HNO_3 , the carbonyl dissolving first, followed by the evolution of NO_2 . Alkalies slowly decompose it. At 100° the material begins to darken; at 140° CO is given off, and at 300° Fe and HgCl_2 are formed. The compd. may lend itself to *detns. of pentacarbonyl*.

H. C. DUUS

Oxidation of sulfur vapor at low pressures. N. SEMENOV AND G. RJABININ. Physics Lab. Leningrad. *Z. physik. Chem. Abt. B* 1, 192-204(1928).—The oxidation by O of S vapor at temps. of 80 - 120° and pressures of approx. 4 mm. has been studied. SO seems to be the principal product, although varying from 20 to 60% of the total amt. of SO and SO_2 . With passage of time the total pressure curve asymptotically reaches a mm. as in the oxidation of P vapor. There is a short induction period dependent upon temp. The min. pressure is independent of the size of reaction chamber and of the presence of foreign gas. There also exists a max. pressure of the S (dependent upon temp.) above which the oxidation cannot occur. Above the max. and below the min. pressures the reaction velocity is immeasurably slow. S and R . believe that either O_3 mols. or an active S atom initiates a chain reaction by inducing the formation of centers.

WILLIAM E. VAUGHAN

Disintegration of calcium carbide in the air. W. SCHERUHN. Untersuchungs u. Prüfstelle deut. Acetylenvereins. *Acetylen in Wissenschaft u. Ind.* 31, 129-31(1928).—Discussion and exptl. data on the influence of atm. humidity, state of division of the carbide, C_2H_2 yield, etc. More finely divided carbides and carbides of lower yield disintegrate more rapidly. The influence of atm. temp. variations is negligible, but in carbide lying in a generator, sufficient heat accumulates to show the accelerating effect of temp.

F. S. GRANGER

Calcium carbide reduction of oxides. ROBERT SAXON. *Chem. News* 137, 216 (1928). To reduce certain difficultly reducible oxides to metal (e. g., those of Mn , Cr , Al , Mg , W and Zr) on a very small scale for class-room demonstration, S . places a mixt. of the oxide with CaC_2 and CaO or $\text{Ca}(\text{OH})_2$ in a tiny crucible or a "straw" clay pipe. The latter is placed inside the tube of a gas burner (bent over and downwards) which is then lighted, and then a blast flame is placed beneath the crucible or pipe.

E. G. R. ARDAGH

Basic carbonates of beryllium. TSUNEKICHI NISHIMURA AND TAKEMARO YAMAMOTO. *Bull. Inst. Phys. Chem. Research* (Tokyo) 7, 920-33(1928); English Ed. 1, 89-90. A double decompn. between a BeCl_2 soln. satd. with CO_2 at 0° , and a satd. soln. of NH_4Cl gives a Be carbonate contg. more than 0.4 mol. CO_2 to 1 mol. BeO . If the initial solns. are more dild. than 1 N , the carbonate pptd. is generally of the form $3\text{Be}(\text{OH})_2\cdot\text{CO}_2\cdot n\text{H}_2\text{O}$, (A). The carbonate obtained by double decompn. at room temp. in the absence of CO_2 is always of high basicity; its compn. is variable. At 100° , the ppt. is practically pure $\text{Be}(\text{OH})_2$. If a deposit of Be carbonate poor in CO_2 be exposed for a long time in a wet or dry CO_2 atm., the final product acquires generally formula A , except in some rare cases where compds. very rich in CO_2 are obtained; the latter are not believed to be stable. If CO_2 is passed for a long time through a suspension of basic carbonate at 25° , a compd. similar to A forms first; after a while, it will decompose, finally yielding a salt contg. only 0.284 mol. CO_2 per mol. BeO . This corresponds to a formula: $7\text{Be}(\text{OH})_2\cdot 2\text{CO}_2\cdot m\text{H}_2\text{O}$. If a suspension of $\text{Be}(\text{OH})_2$ is treated in the same manner, the same carbonate is finally obtained. Be carbonate is unstable in air but decomposes slowly when dry. When a suspension of A in a large quantity of H_2O is treated with air for a long time, decompn. occurs rapidly; two intermediate products are detectable; the final product contains only 0.01 mol. CO_2 per mol. BeO . The same product is obtained from $\text{Be}(\text{OH})_2$ suspensions treated with air.

The chlorides of ruthenium. (Remarks on the work of Gall and Lehmann.) E. ZINTL AND PH. ZAIMIS. *Ber.* 61B, 2110-11(1928); cf. *C. A.* 21, 2081; 22, 3595.—Polemical. HANS C. DUUS

The chlorides of ruthenium. (Reply to remarks by H. Gall and G. Lehmann.) H. REMY. *Ber.* 61B, 2109-10(1928); cf. *C. A.* 22, 3595, 2521.—Polemical. HANS C. DUUS

The induction by sodium thiosulfate of the oxidation of potassium nitrite by iodine. A. BORTHOUD AND W. E. BERGER. *J. chim. phys.* 25, 562-7(1928).—See *C. A.* 22, 1923. E. H.

Decomposition of sodium thiosulfate in acid solution. F. H. RIESENFELD AND G. SYDOW. Univ. Berlin. *Z. anorg. allgem. Chem.* 175, 49-73(1928).—R. and S. have developed the following new method of analysis for the mixt. of products produced by the reaction between HCl and $\text{Na}_2\text{S}_2\text{O}_3$. (1) The sum of SO_3 and S_2O_3 is detd. by titration with I. (2) SO_3 is detd. by conducting a rapid stream of air through the mixt. for about 10 min., collecting the SO_2 in a standard I soln. and titrating the excess of I with $\text{Na}_2\text{S}_2\text{O}_3$. (3) The sum of S_2O_3 , S_3O_6 , S_4O_6 and S_5O_6 is detd. by treatment with HgCl_2 , all of these reacting to form $\text{Hg}_3\text{S}_2\text{Cl}_2$, followed by addn. of NH_4Cl soln. and titration with 0.1 N KOH with Me orange. (4 and 5) The sum of S_4O_6 and S_5O_6 is detd. by neutralization of the soln. followed by addn. of an excess of SO_3 , the polythionates being converted into S_3O_6 and S_2O_3 , the excess of SO_3 being taken care of with CH_2O and the S_2O_3 formed detd. by titration with I. Another method is by reduction with KCN and detn. of the S_2O_3 produced (6) SO_4 is pptd. with benzidine and titrated with KOH. (7) S is filtered off, oxidized to H_2SO_4 and pptd. as BaSO_4 . The reactions between 2.5 N $\text{Na}_2\text{S}_2\text{O}_3$ and 2.5 N HCl, with and without the addition of 0.05 mols. As_2O_3 per mol. of S_2O_3 and the reactions between 2.0 N $\text{Na}_2\text{S}_2\text{O}_3$ and 9.7 N HCl with and without addition of As_2O_3 are studied. Based upon the use of 16.787 millimols of S_2O_3 in every case and a reaction time of 2 days, the following results are obtained expressed in millimols. For 2.5 N $\text{Na}_2\text{S}_2\text{O}_3$ + 2.5 N HCl, without As_2O_3 : S = 7.85, SO_3 = 0.52, SO_2 = 1.64, S_2O_3 = 2.53, S_3O_6 = 2.79, S_4O_6 = 2.17, S_5O_6 = 0.37. The same mixt. + As_2O_3 : S = 8.62, SO_4 = 0.48, SO_3 = 0.09, S_2O_3 = 2.95, S_3O_6 = 3.78, S_4O_6 = 1.34, S_5O_6 = 0.20. For 2.0 N $\text{Na}_2\text{S}_2\text{O}_3$ + 9.7 N HCl, without As_2O_3 : S = 16.13, SO_3 = 0.27, SO_2 = 11.64, S_2O_3 = 0.0, S_3O_6 = 0.0, S_4O_6 = 1.66, S_5O_6 = 0.11. The same mixt. + As_2O_3 : S = 2.10, SO_4 = 0.27, SO_3 = 2.35, S_2O_3 = 3.65, S_3O_6 = 0.0, S_4O_6 = 0.0, S_5O_6 = 4.60. The following reaction mechanism is given. S is formed primarily according to the equation $\text{S}_2\text{O}_3 + \text{H} \rightarrow \text{HSO}_3 + \text{S}$ (1), with some slight reaction as follows: $\text{S}_3\text{O}_6 \rightarrow \text{S} + \text{SO}_3 + \text{SO}_4$. Trithionic acid is the principal product among the polythionic acids when dil. HCl is used in the absence of As_2O_3 . The S_3O_6 first formed as follows $5\text{S}_2\text{O}_3 + 6\text{H} \rightarrow 2\text{S}_3\text{O}_6 + 3\text{H}_2\text{O}$ (2) is decomposed according to the equations: $\text{S}_3\text{O}_6 + \text{SO}_3 \rightarrow \text{S}_4\text{O}_6 + \text{S}_2\text{O}_3$ (3) and $\text{S}_3\text{O}_6 + \text{SO}_3 \rightarrow \text{S}_4\text{O}_6 + \text{S}_2\text{O}_3$ (4). The last of these takes place very slowly, however, and the chief source of S_3O_6 is probably as follows: $\text{S}_2\text{O}_3 + 4\text{HSO}_3 + 2\text{H} \rightarrow 2\text{S}_3\text{O}_6 + 3\text{H}_2\text{O}$ (5). In strong acid solns. without As_2O_3 , tetrathionic acid predominates and all the $\text{Na}_2\text{S}_2\text{O}_3$ has been destroyed. The final end products of the reaction $4\text{S}_2\text{O}_3 \rightarrow 3\text{SO}_4 + 5\text{S}$ are attained only after about 6 months' time. The presence of As_2O_3 in strong acid soln. causes pentathionate to be the chief product and the only polythionate produced. Reaction (1) above is prevented, which likewise prevents (3), (4) and (5) and the pentathionate formed therefore in reaction (2) is not decomposed.

H. STOERTZ

A compound of sulfur and sulfurous acid. A. KURTENACKER AND A. CZERNOTZKY. Tech. Hochschule, Brunn. *Z. anorg. allgem. Chem.* 175, 231-40(1928).—If when H_2SO_3 reacts with $\text{Na}_2\text{S}_2\text{O}_3$, the mixt. is allowed to stand for a few days, the complex ion $[\text{S}_2\text{O}_3\text{SO}_2]$ is partly converted into a loose compd. between S and SO_2 as follows: $[\text{S}_2\text{O}_3\text{SO}_2] + \text{H}_2\text{O} \rightleftharpoons [\text{S}_2\text{O}_3\text{SO}_2\text{H}_2]$; $[\text{S}_2\text{O}_3\text{SO}_2\text{H}_2] \rightleftharpoons [\text{S}(\text{SO}_2\text{H})_2]$. By treatment with CH_2O and NaOH this complex is decompd. with the pptn. of S: $[\text{S}(\text{SO}_2\text{H})_2] \rightleftharpoons \text{S} + 2\text{SO}_2\text{H}'$. Lowering acidity in the absence of CH_2O , as produced by neutralization with AcONa, leads to the formation of S_2O_3 : $[\text{S}(\text{SO}_2\text{H})_2] + \text{OH}' \rightleftharpoons \text{S}_2\text{O}_3 + \text{SO}_3\text{H}' + \text{H}_2\text{O}$. Expts. show that the reaction with CH_2O and NaOH proceeds more rapidly than the decompn. with AcONa. As an excess of SO_2 is always present, only traces of polythionates are formed. In the reaction between $\text{Na}_2\text{S}_2\text{O}_3$ and HCl (dil. or concd.) this compd. between S and SO_2 is also formed. H. S.

Preparation of a tungsten carbonyl by the intermediary of magnesium derivative. ANDRÉ JOB AND JEAN ROUVILLOIS. *Compt. rend.* 187, 504-5(1928).—By methods which had been used for the prepn. of chromium carbonyl (cf. *C. A.* 20, 3404) tungsten

carbonyl, $W(CO)_6$, was prepd. from WCl_6 . The colorless cryst. carbonyl is slightly sol. in C_2H_5O , $C_4H_{10}O$ and C_6H_6 . It sublimes at 50° . The same method is given for the prepn. of $Mo(CO)_6$, but it has already been prepd. by direct action of CO on Mo by L. Mond, H. Hirtz and M. Cowap.

L. D. ROBERTS

Complex compounds of bivalent silver. (A study on the relation between ring closure and "specific affinity.") W. HIEBER AND F. MÜHLBAUER. *Univ. Heidelberg. Ber.* 61B, 2149-53(1928); cf. *C. A.* 22, 1920, 1957.—A soln. of $AgNO_3$ interacts with a soln. of *o*-phenanthryline to give a colorless gelatinous ppt. which may subsequently be oxidized with $(NH_4)_2S_2O_8$ to give a reddish brown substance, $Ag_2O \cdot 2C_{12}H_8N_2$, in quant. yield. It is sol. in cold 64% HNO_3 and the perchlorate is prepd. by adding $NaClO_4$. The chlorate is prepd. by adding $KClO_3$. Both the chlorate and perchlorate are explosive. The salts are capable of oxidizing H_2O_2 , alkali halides and NH_3 . The state of oxidation was detd. with standardized oxalic acid, by measuring the CO_2 evolved. The formation of these compds. of bivalent Ag is explained by the theory that phenanthroline forms a complex ion with the Ag, and the resulting ring is stable. H. C. D.

Reactions and derivatives of iron carbonyl. II. A new type of carbon monoxide compound of the iron halides. WALTER HIEBER AND GEORG BADER. *Universitt Heidelberg. Ber.* 61B, 1717-22(1928); cf. *C. A.* 22, 1957.—Tetracarbonyl-ferrous iodide, $Fe(CO)_4I_2$ (I), is obtained in red, dichroic crystals by evapg. an Et_2O soln. of $Fe(CO)_5$ and I_2 . $Fe(CO)_4Br_2$ (II), red-brown powder from petroleum ether in the cold. $Fe(CO)_4Cl_2$ (III), is prepd. similarly but at -20° as a yellow powder which loses CO at room temp. II and III are instantly decompd. by H_2O , III only on heating. NH_3 eliminates CO from these compds. producing hexamine-ferrous halides. Amines, alcs., esters, aldehydes and ketones cause decompn. of these salts although III is stable toward certain agents that decomp. I and II. Pyridine converts I and II into $FeX_2 \cdot (C_5H_5N)_2$, while III yields $Fe(CO)_2(C_5H_5N)_2I_2$ (IV), green needles, and $Fe(C_5H_5N)_4I_2$. IV spontaneously loses CO, yielding monocarbonyldipyridine-ferrous iodide, $Fe(CO)(C_5H_5N)_2I_2$. Excess of C_5H_5N produces $[Fe(CO)(C_5H_5N)_3]I_2$. Light causes the complete elimination of CO from I, II and III, their stability decreasing from I to III.

7—ANALYTICAL CHEMISTRY

W. T. HALL

Centrifugal analysis as a rapid analytical method. CARL HÜTTER. *Metall u. Erz* 25, 273-5(1928).—A centrifuge for the sepn. of mineral or ore mixts. (0.5-3 g.) is described, in which 4 small tube furnaces are suspended from a body rotated at 2000 r. p. m. by a small motor. The furnace temp. is controlled by a rheostat, up to 900° being obtainable. The power consumption is 2 amp. at 220 v. at the max. The centrifuging medium may consist of salts (or their mixts.), or light metallic alloys. If the sepn. is not complete after the first centrifuging, fractional centrifuging may be resorted to.

J. BALOZIAN

Centrifugal analysis as a rapid analytical method. The correct situation. v. WOLFF. *Metall u. Erz* 25, 327-8(1928).—W. claims that the app. indicated by Hütter (cf. preceding abstract) was first described by him (v. W.). H. replies to the claim.

J. BALOZIAN

Gravimetric titration and its application to microchemical determinations. B. ORMONT. *Z. anal. Chem.* 75, 209-28(1928).—The term "gravimetric titration" signifies the titration of a weighed quantity of soln. by means of a soln. contg. a known weight of active reagent per kg. of soln. Just as there is *N*, 0.1 *N*, 0.01 *N*, etc., solns. it is now proposed to have *P*, 0.1 *P* and 0.01 *P* solns. in which the concn. is expressed in equiv. per kg. instead of equiv. per l. According to O., the methods of quant. analysis embody methods of (1). Weight Analysis, or what has formerly been called "gravimetric" methods and (2). Titration Analysis which includes gravimetric and volumetric titrations. The advantages of carrying out the titrations gravimetrically are discussed with careful consideration of the various sources of error. In particular the method is applied to the titration of HCl solns. with Na_2CO_3 solns. and of arsenite with iodine solns. contg. $0.6-2.6 \times 10^{-4}$ mg. of HCl and $0.7-3.5 \times 10^{-4}$ mg. of As_2O_3 .

W. T. H.

Macro- and micro-iodometric determination of copper in salts of organic acids and enols. M. USHAKOV. *Univ. Moscow. Z. anal. Chem.* 75, 228-35(1928).—The method consists merely in dissolving a weighed quantity of substance in 20 cc. of water, or alc., adding 10 cc. of 10% H_2SO_4 and 10 cc. of 10% KI soln. The liberated I_2 is

titrated with $\text{Na}_2\text{S}_2\text{O}_3$. This method succeeds in the presence of enols, aliphatic and aliphatic-cyclical amino acids, cyclical aminosulfonic acids, aliphatic and aliphatic-cyclical acids with a double bond and cyclical nitro acids. It cannot be used in the presence of sulfonic acids.

W. T. H.

Simplified method for potentiometric titrations. ERICH MÜLLER AND HERBERT KOGERT. Sachs. Tech. Hochschule Dresden. *Z. anal. Chem.* 75, 235-9(1928).—Further details are given concerning the usefulness of the very simple titration electrode which was described recently (*C. A.* 23, 52).

W. T. H.

The application of Emich's filtering tubes in potentiometric titrations. THEODOR HEČZKO. *Z. anal. Chem.* 75, 183-90(1928).—One of the reasons why potentiometric methods have been adopted more generally in industrial labs. is on account of the fact that the app. usually recommended is expensive. In this paper, a method of titrating is described which is inexpensive. As comparison electrode, a quartz filtering tube with porous bottom is used. The tube is about 4.8 cm. long, the diameter of the filtering plate about 1 cm., that of the inside of the tube is 1 mm. and the tube will hold 0.25 cc. of liquid. For the titration of Fe^{++} , the tube is filled with a mixt. of acid 0.05 *N* FeSO_4 and 0.05 *N* $\text{Fe}_2(\text{SO}_4)_3$ solns. For the titration of VO_3^{++} the tube is filled with VO_3^{++} soln. to which enough MnO_4 has been added to provide some quinquevalent V. For the Zn titration, the tube is filled with $\text{K}_4\text{Fe}(\text{CN})_6$ soln. contg. a little ferricyanide, and for the titration of Ag, a dil. AgNO_3 soln. is used. Inside this tube is a wire of suitable metal. A variable resistance can be made from a 50-cc. measuring cylinder filled with 0.1 *N* CuSO_4 soln. The cylinder is provided with a stopper through which a capillary tube is inserted carrying a wire electrode and another wire reaching to the bottom of the soln. serves as the other electrode. The resistance of a CuSO_4 soln. in the measuring cylinder is detd. by the distance between the 2 electrodes. The only other app. needed are a stirrer and a galvanometer. The prepn. and use of this simple arrangement are described in detail and a no. of typical analyses given to show the accuracy of the results obtainable.

W. T. H.

The Prussian blue and Turnbull's blue test. L. SZEBELLÉDY. Univ. Budapest. *Z. anal. Chem.* 75, 165-7(1928).—The blue test for Fe^{+++} with 5 cc. of 0.02 *N* FeCl_3 is completely obscured by 0.5 g. of NH_4F in the presence of which a white ppt. is formed. Smaller quantities of NH_4F make the test paler and pinker in appearance. The test for Fe^{++} with $\text{K}_3\text{Fe}(\text{CN})_6$ is weakened similarly. With corresponding concns. the ppt. is white when 0.3 g. of NH_4F is present. A ppt. of Prussian blue is not whitened readily by adding NH_4F but this is the case with a ppt. of Turnbull's blue.

W. T. H.

Detection of cadmium by microchemical method. P. G. POPOV. *Ukrainskii Khim. Zhurnal* 3, No. 2, Pt. sci., 157-60(1928).—The following procedure is suggested for the detection of Cd in acid soln. in the presence of Hg, Ag, Pb, Cu and Bi. Evap. a few drops of the soln. contg. the above metals with H_2SO_4 to remove all HNO_3 . To the soln. of the sulfates add powd. Fe, stir and immediately filter. Treat the filtrate on a watch glass with a soln. of H_2S . The same method can be applied for the detection of Zn if Cd has been shown to be absent. After the addn. of Fe heat the soln. until all free acid has been removed, filter, add AcOH and treat the soln. as before with H_2S .

G. B. KISTIAKOWSKY

Rapid method for the simultaneous determination of silver and cadmium by the potentiometric method. ERICH MÜLLER AND HERBERT HENTSCHEL. Sachs. Tech. Hochschule Dresden. *Z. anal. Chem.* 75, 240-4(1928).—The titration takes place in much the same way as has been described for the detn. of Ag and Zn (*C. A.* 22, 1929) but NaBr should be used instead of NaCl and $\text{Na}_4\text{Fe}(\text{CN})_6$ instead of $\text{K}_4\text{Fe}(\text{CN})_6$. It is possible to titrate Ag, Pb and Cd, when present together. Titrate first the Ag with NaBr using an electrode of Ag for comparison, then replace this electrode with a Pt one and titrate the Pb and Cd with $\text{Na}_4\text{Fe}(\text{CN})_6$. In another sample, remove the Ag with NaBr and the Pb with Na_2SO_4 and titrate the Cd with $\text{K}_4\text{Fe}(\text{CN})_6$.

W. T. H.

Separation of cadmium from copper in qualitative analysis. P. G. POPOV. *Ukrainskii Khim. Zhurnal* 3, No. 2, Pt. sci. 153-5(1928).—A modification of Castle's method (*Am. Chem. J.* 2, 503(1889)) of sepg. Cd from Cu in acid soln. by Fe. The new feature is the use of powd. Fe which speeds up the procedure and obviates the otherwise necessary heating. After adding Fe powder stir the soln. for 10-20 secs. and immediately filter. Det. Cd in the acid filtrate by pptg. with H_2S . Powd. Zn can be used instead of Fe, but the soln. must remain acid during filtration, as otherwise not only Cu but also Cd will be pptd.

G. B. KISTIAKOWSKY

Detection of copper in the presence of iron. L. SZEBELLÉDY. Univ. Budapest. *Z. anal. Chem.* 75, 167-8(1928).—In the presence of 1 g. of NH_4F the test for Cu is more sensitive than otherwise. As little as 0.013 mg. of Cu can be detected in 5 cc. by the

addn. of a few drops of 1% $K_4Fe(CN)_6$ soln. If, at the same time, 0.1 g. of Fe^{+++} is present, the test is not obscured. W. T. H.

Determination of sulfur in copper alloys containing tin. H. LEYSAHT. Materialprüfungsamt Berlin. *Z. anal. Chem.* 75, 169–82(1928).—The gravimetric detn. of S in bronze after treatment of the alloy with HNO_3 is a tedious procedure and one likely to give inaccurate results. It is possible to avoid the trouble caused by Sn by distg. off the Sn as $SnBr_4$ and, similarly, by decomposing the alloy with $KClO_3$ and Br_2 it is possible to get good results although considerable skill and patience are required. It is much more convenient to carry out the detn. by an evolution method similar to that used for the detn. of S in steel but treating 5 g. of material with 50 cc. of HBr soln. d 1.49 contg. sufficient $SnCl_2$ to remove any free Br_2 . The H_2S evolved can be absorbed in Br-HCl and detd. as $BaSO_4$ as recommended by Bauer and Deiss or the H_2S can be absorbed by $Cd(OAc)_2$ soln. as in steel analysis, taking care first to wash the gas free from the greater part of the HBr in the vapors by bubbling through a little water. Toward the end of the distn. this water is heated nearly to boiling so that it does not retain H_2S . Expts. with HBr and steel samples showed that either HCl or HBr can be used for the analysis of steel by the evolution method but the attempt to substitute HCl for HBr in the analysis of bronze gave values much too low, as might be expected. W. T. H.

Detection of arsenic. DAUVÉ. *Ann. chim. anal. chim. appl.* 10, 320–1(1928).—In Wurtz' dictionary, a test for As is given which consists in treating the substance with a little NaOH soln. and a piece of Al and allowing the liberated gas to come into contact with paper impregnated with $AgNO_3$. Unfortunately Al foil almost always contains sufficient Si to give the blackening of the $AgNO_3$ paper by SiH_4 . The test can be modified to avoid this difficulty by using a paper which has been impregnated with a drop of $HgCl_2$ soln. The $HgCl_2$ gives a yellowish color by contact with a little AsH_3 , whereas it is not acted upon by SiH_4 . A simple app. is depicted for carrying out the test. The test proceeds in dil. and in dil. alk. soln. W. T. H.

Determination of chlorine in benzaldehyde by the so-called combustion method. R. D. HENDRIKSZ AND A. RECLAIRE. Polak and Schwarz, Hilversum, Holland. *Parfums de France* 6, 273–4(1928).—The disadvantages of the Rubke method for the detn. of Cl in benzaldehyde are eliminated without interfering with its accuracy by mixing the benzaldehyde with an equal vol. of alc. before burning. A. PAPINEAU-COUTURE

Method for the determination of halogen or sulfur present in small quantities in organic substances, especially those containing chromium. FR. HEIN, K. HOVER AND K. KLAR. Univ. Leipsic. *Z. anal. Chem.* 75, 161–4(1928).—For the detn. of halogen, mix 0.02 g. of the substance with 0.18 g. of pure sugar and 2–2.5 g. of Na_2O_2 in a Pringsheim crucible (*C. A.* 3, 647) (taking care not to heat by grinding) and finally adding 2 g. more of the peroxide as a cover. Place the crucible in a porcelain dish contg. sufficient water to half cover the crucible. Start the reaction by means of a glowing nail and cover the crucible quickly. After 15 min., turn over the crucible so that water enters and cover the dish with a watch glass. Heat to about 95° for 15 min., make acid with HNO_3 and add 1–2 cc. of SO_2 soln. Heat 2 hrs. on the water bath and then add H_2O_2 till the excess SO_2 is removed. Add 3 cc. of concd. HNO_3 , cool to 20° and add a measured vol. of standard $AgNO_3$ soln. Titrate the excess with NH_4CNS soln. using ferric alum as indicator. For the detn. of S, use HCl instead of HNO_3 and reduce the CrO_4^{--} by alc. and a crystal of $NaNO_2$. Then allow the cold soln. to flow slowly into a hot, ammoniacal soln. of $BaCl_2$, make acid with HCl and filter off the $BaSO_4$ ppt. W. T. H.

Hypophosphoric acid. W. D. TREADWELL AND GEROLD SCHWARZENBACH. *Helv. Chim. Acta* 11, 405–16(1928). (A correction.)—For the titration of $H_4P_2O_6$, $U(SO_4)_2$ and not UO_2SO_4 must be used (*cf. C. A.* 22, 3109). W. T. H.

The volumetric determination of sulfuric acid. G. TESTONI. *Ann. chim. applicata* 18, 408–14(1928).—A modification of the method of Raschig (*Z. angew. Chem.* 617–8(1903)) based on the insoly. of benzidine sulfate. The end point is detd. by testing with filter paper moistened with PbO_2 which will give a purple color with 1 part in 200,000 of benzidine. The standard benzidine soln. is made by dissolving 10 g. of this in 100 cc. AcOH (glacial) and dilg. to 1 l. Let stand one day, then filter and titrate with 0.1 N H_2SO_4 . For the greatest accuracy the soln. contg. SO_4 is titrated, filtered, and the filtrate tested for excess benzidine with PbO_2 . When 2 titrations are made using amts. of benzidine differing by 0.1 cc. in which the filtrate of one has excess benzidine while the other has none, then the av. of these 2 is taken. Chromates and other oxidizing agents present must be reduced, while ferric salts must be removed. The sulfate soln. must be slightly acid with AcOH, as free mineral acids interfere with

the end point. This is a rapid method giving results within 1% or better. The use of AcOH also prevents occlusion of benzidine in the ppt. as is the case when the hydrochloride is used.

A. W. CONTIERI

The determination of nitrogen peroxide vapors in air and its usefulness in industrial hygiene. E. KOHN-ABREST. *Chimie et industrie Special No.*, 947-9 (April, 1928).—After a criticism of various methods, the following is recommended: exhaust a 4 l. glass-stoppered bottle carrying 2 glass tubes with stopcocks, fill it with the air to be examd. until the pressure is slightly less than atm., add 10 cc. 0.1 N NaOH and 50 cc. H₂O (2NO₂ + 2NaOH = NaNO₂ + NaNO₃ + H₂O), shake 5 min., to 30 cc. add 3 cc. of 20% H₂SO₄ (by vol.) and 25 cc. H₂O, and titrate with KMnO₄ till the color persists for 3 min. One cc. 0.1 N KMnO₄ = 0.0046 g. NO₂. The results can be confirmed by detn. of nitrates in the oxidized soln. by the method of K.-A. and Kawakibi (*C. A.* 21, 367). Examn. of the air in the neighborhood of a George 1500-c. p. quartz lamp operated in an 18-cu. m. room gave neg. results, even after 30 mins.' operation, the odor being due exclusively to the production of O₃. The work of Dadlez on the production of NO₂ in clinical elec. treatments is briefly reviewed (see *C. A.* 21, 3973). A. P.-C.

Report on chemical reagents. (Determination of sulfates in ammonium nitrate.) G. C. SPENCER. Bureau of Chemistry and Soils, Washington, D. C. *J. Assocn. Official Agr. Chem.* 11, 421(1928).—The following procedure is recommended: digest 5 g. of sample with 20 cc. concd. HCl in a 500-cc. Kjeldahl flask (not previously used for H₂SO₄ digestions) on a steam bath or over a low flame, renewing the HCl lost by evapn., until a piece of starch-KI paper is only slightly colored by the fumes, transfer to a 100-cc. beaker, evap. to dryness on a steam bath, take up in a little H₂O and 2 cc. concd. HCl, filter if necessary, and ppt. SO₄ as usual.

A. PAPINEAU-COUTURE

Colorimetric estimation of turbidity of silver chloride and of barium sulfate. S. AOYAMA AND T. DAIGO. Tokyo Imp. Hyg. Lab. *J. Pharm. Soc. Japan* 48, 702-12 (1928).—To det. the amt. of HCl and its salts present as impurities in various substances, the turbidity caused by AgCl ppt. was measured by a colorimeter. By using the "Opalsierende Trübung" of the German Pharm. as units, the relative turbidity of the standard solns. in both the German and American Pharm. was measured and numerically expressed. The turbidity does not necessarily correspond with the increase in acidity although it is greater in an acid medium than in a neutral medium. It is recommended to use the standard in HNO₃ medium, also the use of Walpole's comparator when the soln. is colored. AgCl standard cannot be used for BaSO₄ ppt. Time for the pptn. of BaSO₄ should be 15 min. instead of 10 min. in making measurement. NAO UYGI

Toxicology of lead and its compounds. VI. Distribution of lead in the organism, especially in the bones, and the toxicity of lead solutions to fish. P. W. DANCKWORTT AND E. JÜRGENS. *Arch. Pharm.* 266, 492-501(1928); cf. *C. A.* 22, 3373.—A procedure has been developed for the detn. of Pb in the bones. The chem. examn. of dogs poisoned by Pb afforded a survey of the distribution of that element in the organism. The relatively low content of Pb in the organs leads to the conclusion that this element is carried by the blood to the bones. The flattened bones carry a higher Pb content than those of tubular structure. The Pb content of H₂O exercises an influence on the life of fish.

W. O. E.

Determination of pyruvic acid. BASETTIHALLI HANUMANTHA, RAO KRISHNA AND MOTNAHALLI SREENIVASAYA. Indian Institute of Science, Bangalore. *Biochem. J.* 22, 1169-77(1928).—The method is a modification of Lieben's technic (*C. A.* 17, 2740) and is based upon the following reactions: CH₃CO.COOH + 2H → CH₃CHOH.COOH; and CH₃CHOH.COOH + O → CH₃CHO + CO₂ + H₂O. B. H.

Rapid method for the determination of the dry picric acid content of a moist sample and its application to the calculation of the yield in nitration experiments of phenol. LOUIS DESVERGNES. *Ann. chim. anal. chim. appl.* 10, 317-20(1928).—The moisture content of picric acid cannot be detd. satisfactorily by oven drying. From the d. of dry picric acid (0.9060) and the d. of a satd. soln. of picric acid in water (1.005) it is possible to compute the moisture content by introducing a weighed quantity of the sample (say 33 kg.) into a measuring vessel together with some water (say 12 kg.) and then measuring the vol. and detg. the wt. of the mixt.

W. T. H.

A new colorimetric test for tannic acid. J. RAE. *Pharm. J.* 120, 539(1928).—A 10% aq. NH₄ molybdate soln. (A) produces with soln. of tannic acid at once a reddish brown permanent color, varying in intensity with the concn. of tannic acid. The test is positive also with gallic acid, pyrogallol and tincture of catechu, *Brit. Pharm.*, neg. with dextrose, resorcinol, glycerol, PhOH or EtOH. Hydroquinone and phloroglucinol produce a very pale yellow, in concd. solns. only. To det. tannic acid in *glycerinum acidi tannici*, *Brit. Pharm.* (B) (20%), dil. 5 cc. of B with H₂O to 100 cc.; to 1 cc. thereof

add 2 cc. of *A* and dilⁿ to 50 cc. in a Nessler tube, compare the color with that obtained from a standard 1% aq. soln. of tannic acid. To *det. tannin in tea*, exhaust the tea with boiling H_2O and treat 1 cc. as stated. To eliminate the influence of the color produced by the infusion itself, 1 cc. was dild. with H_2O to 50 cc., and sufficient burnt sugar was added to 50 cc. H_2O to match the color. This colored H_2O was then used in making up the standard in the Nessler tube. A tentative detn. of tannin in *tea*, not verified by another method, gave 10%. Powd. drugs *e. g.*, galls, catechu, etc., when mixed with 1 drop of the reagent gave at once a reddish color. S. WALDBOTT

A microanalytical method of estimation of sulfur in organic compounds. SADAHIKO HANAI. *Bull. Inst. Phys. Chem. Research* (Tokyo) 7, 915-9(1928); English Ed. 1, 86-8.—The method is based on the decompn. of S compds. at 200-500° by Ni catalyst in an H atm. Place a few mg. of substance in a Ptⁿ boat and introduce into a small decompn. tube contg. Ni catalyst. The catalyst is made from NiO (obtained from NiO_4C_2) reduced with H in the tube itself. Pass pure H through the tube, and after the air has been expelled, carefully volatilize the substance so that it passes over the catalyst in the H_2 . Finally, cool the tube, add HCl to the contents and pass the evolved H_2S together with H_2 through an ammoniacal Cd soln. Det. the S content of the pptd. CdS iodometrically as in the detn. of S in steel. A. L. HENNE

Reaction accelerators in the determination of organic nitrogen by Kjeldahl's method. FOSCO PROVVEDI. *Atti accad. fisiocrit. Siena* [10], 3, 423-5(1928).—After expt. with accelerators, reducers and oxidizers under identical conditions on a sample of flour, it was found that decoloration took place with H_3PO_4 - H_2SO_4 in 6 hr. 30 min., reducing agents in 6 hr. 30 min., H_3PO_4 - H_2SO_4 and K_2SO_4 in 5 hr. 30 min., $KMnO_4$ in 3 hr. 30 min., BaO_2 in 3 hr., $(NH_4)_2S_2O_8$ in 3 hr., H_2O_2 in 45 min. the % of N remaining const. at 1.5%. The greater activity of H_2O_2 was due to the other agents reacting with SO_2 originated in the reduction of H_2SO_4 . Other expts. confirmed the errors of considering decoloration as indicator of the end reaction. This is caused by the destruction of C liberated in the principal reaction. After boiling for about 45 min. the result concords with that obtained by boiling until complete decoloration. The N detn. with Kjeldahl's method can therefore be conducted sooner than usually. R. SANBONE

The action of Hg salts on $Fe(CO)_5$, (HOCK, STUHLMANN) 6. Fatal case of acute lead poisoning (BRÜNING, KRAFT) 11H.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

Gypsum in the European part of U. S. S. R. and Caucasus. L. I. SEMIKHATOVA. *Trans. Sci. Inst. Fertilizers* (Moscow) No. 36, 3-51(1926).—S. deals with the gypsum areas in the various parts of European Russia and Caucasus, indicating the geological, petrographic and mineralogical relationships of the deposits. An English summary and a map indicating the extent of the deposits are appended, and a large no. of references to the literature is given. J. S. JOFFE

Remarks on the theory of formation of petroleum and anthracite. A. F. VON STAHL. *Montan. Rundschau* 20, 550-1(1928).—Petroleum and anthracite are both formed by an analogous process: decompn. of org. matter. In the first case, the materials are chiefly of animal origin, in the second, vegetable. Fe and S play an important role. Both are present in living organisms. They are actually found as pyrite and Fe oxide. It is to be noted that in the industrial coal liquefaction process, these elements have an enormous catalytical importance. The decompn. of org. matter yields always oily materials first; these materials may be hardened by oxidation, due to Fe oxide, forming thus anthracite. The presence of oily inclusions in pitch-coal is regarded as a support to the theory advanced. A. L. HENNE

The geological basis for the formation of oil deposits. W. WUNSTORF. *Petroleum Z.* 24, 761-2(1928).—The same conditions were necessary for the formation of oil reservoirs as for the formation of coal deposits, *i. e.*, sediments and both pervious and impervious rock formation. M. B. HART

Earth temperatures in Hannover oil fields. R. HERRMANN. *Petroleum Z.* 24, 241-3(1928).—The development of heat in the region of oil deposits is attributed to the chem. reactions such as depolymerization and subsequent polymerization which take place. Evidences of these reactions such as the presence of lighter oils at lower horizons are observed in the Hannover fields. M. B. HART

Origin of Japanese petroleum. KIUCHEI KOBAYASHI. *Chem. News* 137, 46-7 (1928).—There is a very close geological relation between the oil fields (Echigo, Akita and Aomori) and the outcrops of Japanese acid clay. In Japan, petroleum is almost always accompanied with salt water. By dry distn. of acid clay and NaCl, HCl is obtained. NaCl, AlCl_3 and HCl will affect the formation of petroleum from fish oil in the earth's crust. The origin of Japanese petroleum and natural gas is due to marine animals; putrefaction takes place first, eliminating albumin; fish oils decomp. to fatty acids and glycerol by hydrolysis; petroleum and gas are obtained by distg. a mixt. of these acids and glycerol with acid clay; hydrocarbons of the naphthane series are derived from low unsatd. fatty acids; hydrocarbons of the $\text{C}_n\text{H}_{2n-2}$, $\text{C}_n\text{H}_{2n-4}$, etc., series are derived from highly unsatd. fatty acids. A 62% yield of oil has been obtained exptly. by distg. sardine oil with acid clay. A. L. HENNE

Changes of certain clays into acidic ones through weathering. Preliminary. TSURUJI OKAZAWA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 776-84 (1928); English Ed. 1, 69-70.—O. examd. a no. of mountains producing acidic clays in Japan; he found that acidity is limited to the upper surface and decreases toward the interior, becoming neutral or alk. at last. The appearance of the clay remained the same throughout, the clay being derived from igneous formations. The strength of the acidity differs for individual mountains but is generally stronger for those which lie closer to the sea coast. The depth to which the acidity subsists is nearly proportional to the strength shown in the upper surface. In the mountains with the strongest acidity, a feeble acidity is traceable to a vertical depth of 12 m.; in mountains with weak acidity the clay is already neutral at a depth of 2 m. In Japan the acidic mountains are generally located in the provinces facing the Sea of Japan. Wind is generally severe there during autumn and winter, and snow rich in NaCl falls abundantly even to a depth of 4-5 m. The salinity is so intense that maple trees cannot grow fully near the coast. O. believes that the acidity is due to a chem. decompn., and not to mech. adsorption. Acidic clay is formed from the original substance by weathering by saline wind, rain and snow. This explains the rarity of this phenomenon near the Pacific coast, and inland. A. L. HENNE

Adsorption of acid and acidic salt (acidity of acidic earth and alkaline earth). HAJIME ISOBE AND YOSHIOMI YENDO. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 805-20 (1928); English Ed. 1, 72-4.—The acidity of acidic earth is caused by small quantities of acid and acidic salts strongly adsorbed by the earth. A portion of the acid and the acidic salts is combined as a complex salt and retained in the earth by residual affinity; the other portion is simply adsorbed. The acidity may be reduced by treating with boiling H_2O . The origin of the acid and acidic salts is due to weathering. In the upper layer of the earth, AlCl_3 is produced by sea water and active Al present in the earth; CO_2 is produced by org. matter and also comes from the air. In the lower layer, $\text{Al}_2(\text{SO}_4)_3$ is produced by oxidation of sulfides present in the earth. A. L. HENNE

Occurrence of iodine and the iodine cycle. A. E. ALFTHAN. *Finska Kemist-samfundets Medd.* 37, 8-19 (1928).—Review of von Fellenberg's work on I in Switzerland (*C. A.* 21, 3910 and earlier references). HANS C. DUUS

X-ray phosphorescent and thermophosphorescent radiations of kunzite (STUHLMAN, DANIEL) 3. Natural blue rock salt (PRZIBRAM) 3. The preparation of thin sections of friable rock (LEGGETTE) 2.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, R. H. ABORN

Russia's non-ferrous metal industry in 1926. L. VON MÜHLEN. *Metall u. Erz* 25, 270-3 (1928).—A brief survey. J. BALOZIAN

The separation and concentration of ores by flotation. CH. BERTHELOT. *Rev. métal.* 25, 372-96, 411-26, 496-508 (1928).—A general review of the principles of the process as applied to various types of ores, with a description of its applications, particularly in the United States, Canada and Australia. A. PAPINEAU-COUTURE

African gold and silver quartz ore. P. SPORCQ. *Ing. chim.* 16, 121-3 (1928).—Ag and Au are not alloyed but are included in the pyrites. The extn. of each varies

with the ρ_H of the flotation agent. The silver is much more finely divided than the gold.

P. THOMASSET

Attempts to utilize pyrites ashes as an iron ore. C. FICAI. *Giorn. chim. ind. applicata* 9, 450-9(1928).—As Italy has no large domestic source of iron, the product remaining from roasting of pyrites is being studied as a possible source of iron, copper is already being recovered commercially from this source.

A. W. CONTIERI

The production of high-quality cast irons, their metallurgical principles and the practical performance. B. OSANN. Bergakademie, Clausthal. *Giesserei* 15, 648-55 (1928).—A theoretical paper. It is shown that the aim of all processes for improving cast Fe is to produce a eutectic compn. The diminishing in the size of graphite is not due to overheating, but to purely mech. processes taking place in the cast Fe. Means of producing C-poor eutectic cast Fe in reverberatory and cupola furnaces are described.

J. BALOZIAN

A survey of the present methods for obtaining high-quality cast iron and views on some furnace questions. LANGENOHL. *Giesserei* 15, 566-71(1928).—A brief description of the methods, theory and furnaces used in the production of high-quality cast Fe.

J. BALOZIAN

The Burgers system of blast furnace with water-cooled metal shaft and without inner brick lining. E. DE LOISY. *Rev. métal.* 25, 557-62(1928).—At the Makiewka plant 2 furnaces were of the same shape and size, one having a Burgers water-cooled, unlined shaft while the second had the ordinary brick-lined shaft, and the same ores were supplied to both. A comparison of operations over a period of 2 yrs. showed that the coke consumption was the same in both (for the same grade of Fe), and that the Burgers furnace had a lower Fe ore and Mn ore consumption and was easier to handle.

A. PAPINEAU-COUTURE

Improved Siemens-Martin furnace with Moll-head. KARL HERMANN MOLL. *Stahl u. Eisen* 48, 1160-5(1928).—The following improvements are described: (1) air chambers placed over the stage; (2) a general easy accessibility to all parts of the furnace; (3) new brickwork built of Moll-Rhenania hollow bricks; (4) gas mains with quadratic cross-sections and the use of the new Moll-Demag valve for air and gas.

J. A. SZILARD

The cupola furnace according to Poumay. C. GEIGER. *Giesserei* 15, 816-9 (1928).—A brief description of the construction and operation of the Poumay furnace, with some exptl. results.

J. BALOZIAN

Accurate temperature measurement in cupola furnace practice. P. RHEINLÄNDER. *Giesserei* 15, 911-7(1928).—A lecture in which the most important methods of measuring the temps. of Fe, in the furnace and in the ladle, and the waste gases are described.

J. BALOZIAN

The quiet pouring of metals and alloys. P. G. DURVILLE. *Rev. métal.* 25, 563-71 (1928).—In the usual methods for the pouring of metals and alloys, the contact of the liquid metal with the atm. undoes the work accomplished in the purification prior to pouring, the extent to which this occurs depending on the conditions of pouring. When Al is present it forms a thin film of Al_2O_3 which protects the metal from oxidation; but this film is not reduced by C under the conditions ordinarily prevailing in the pouring or casting of metals, and the agitation produced by pouring results in a considerable amt. of inclusions which weakens the metal and considerably impairs its quality. These disadvantages can be overcome by die casting; but this is not economically practical except for the production of small and medium-sized pieces in large numbers. The best method available at the present time consists in open-side pouring, which entails a certain complication of the pouring equipment; but this is more than compensated by its advantages.

A. PAPINEAU-COUTURE

Investigations on slag inclusions in steel castings from small Bessemer converters with consideration to the pouring method. L. TREUHEIT. *Giesserei* 15, 585-91(1928).—A chem. and microscopic study is made of the effect on slag inclusions (I) in steels of pouring from a plugged (II) and a tilting (III) ladle, and the influence on pipe formation and the tensile properties. Three fusions (2500 kg. each) are prepd. by blasting a mixt. of 45% crude hematite Fe and 55% scrap steel, and pouring one into a II ladle, a sec. into a III, and a half of the third into a II and the rest into a III ladle. The % I, using only unannealed specimens, is detd. chemically by Eggertz's I_2 -method. The max. amt. of I is found to be 0.18%, the min. 0.1%, specimens poured from the III ladle showing the highest content of I. Microscopically, no difference in I could be detd. in etched and unetched specimens, annealed (5 hrs. at 900°) and unannealed, from the 2 methods of pouring. Steels poured from the II ladle are less inclined to pipe formation than when poured from the III. The tensile strengths of steels are not

affected by the method of pouring or by I. The notch hardness of steel increases with increasing I content, and is greater in those poured from III ladles than from the II.

J. BALOZIAN

Position of the metallurgy of copper at the present time. MARCEL FOURMENT. *Rev. métal.* 25, 481-95(1928).

A. PAPINEAU-COUTURE

Aluminum and the problem of its production. LUDWIK WASILEWSKI. *Przemysł Chem.* 11, 277-89(1927).—The conditions in Poland are favorable for eventual production of Al to supply the home market of 500-1000 tons yearly. Economical power and good electrode material may now be made available. The manufacturing may have to be begun with imported Al_2O_3 but eventually can be made to use the domestic kaolin and clay. A review of several most widely used methods for producing Al constitutes the first part of this article.

A. C. ZACHLIN

The manufacture of pig iron in Natal. J. E. HOLGATE. *J. Chem. Met. Mining Soc. S. Africa* 29, 2-5(1928); cf. *C. A.* 22, 1937; 23, 72.—The prepn. of dry FeO is a difficult matter not easily obtainable under blast-furnace condition. For every ton (909 kg.) of pig iron produced from the raw ore about 2,000,000 thermal units of heat are permanently lost to the furnace by the endothermic decompn. of the carbonate. When a furnace on normal charge is so driven that some reduction in the gas temps. is obtained, it is due to the increased speed of descent of the charge carrying down an increased amount of sensible heat, resulting in conservation of heat rather than loss. Raw ore lessens the output, discounting somewhat the economy indicated. W. H. B.

The manufacture of ferromanganese at the Makiewka plant (Southern Russia). V. G. KOTELNIKOV. *Rev. métal.* 25, 541-56(1928); *J. Russ. Met. Soc.* 1927, No. 4, Mem. 405-33.—A detailed description and discussion are given of the manuf. of Fe-Mn during a period of 17 months, which showed that the requirements for most advantageous production are: an acid slag (e. g., CaO 32-4, SiO_2 30, MnO 18-20, MgO 2, Al_2O_3 9-10%), rich ore (not less than 45% Mn, not more than 10-4% SiO_2), a blast temp. of 750-830°, rapid operation so that the ore does not remain more than 14 hrs. in the furnace. All these conclusions, with the exception of the one as regards the acidity of the slag, confirm those of Royster (*C. A.* 13, 699). The difference in conclusion as regards the compn. of the slag is due to the fact that Royster rendered his slag basic by means of dolomite, which would not be economical at Makiewka; in the latter place basicity would have to be obtained by means of limestone, and the resulting slag gives rise to greater drawbacks than acid slag.

A. PAPINEAU-COUTURE

Some non-ferrous metals used in the electrical industry. ANON. *Electrician* 101, 611 (1928).—A review.

C. G. F.

Iron, steel and ferrous alloys in the electrical industry. J. G. PEARCE. *Electrician* 101, 604-6(1928).—A review.

C. G. F.

Definite procedure required in etching iron and steel. H. H. SHEPHERD. *Foundry* 56, 785-8(1928).—The various etching agent and etching procedures used on iron and steel are discussed, with some critical notes on recommended practice. Seven photomicrographs are given in illustration.

ROBERT F. MEHL

Application of metallography in improving the quality of iron and steel. H. MEYER. *Stahl u. Eisen* 48, 506-15(1928).—The use of metallographic methods in the detection of segregations, blow holes and recrystn. in Fe and steel is described and numerous practical examples are given.

J. A. SZILARD

The mechanism of crystal growth by annealing. TOMIYA SUTOKI. *Science Repts. Tôhoku Imp. Univ.* 17, 857-76(1928).—Crystal growth in metals by annealing after plastic deformation and by annealing only was studied. In the first case, single crystals of Al were shown to grow at the expense of minute grains, but between crystals of macroscopic size no union was observed, even after very long annealing. In the second case, the concave side of the grains of a Sn-Sb alloy (1.5% Sb) absorbed, in most cases, the adjacent convex grains, the curvature of the boundary gradually diminishing. The crystal growth which takes place in the boundary of neighboring crystals is according detd. by the conditions of the atoms in the boundary layer; i. e., when the mobility of atoms is promoted by heating, an atom in the boundary layer may be attracted from those of the adjacent crystal and enter into it to form the lattice, then a new atom from the other crystal will occupy the position of the former atom and will again be attracted by the adjacent crystal and so on, and thus by a repetition of this process the former crystal will grow at the expense of the latter. The chief function of plastic strain is to produce nuclei of crystal growth, the no. being dependent on the amt. of strain. The no. of nuclei must be as small as possible, and the strain must be the critical value to obtain large single crystals.

DOWNES SCHAAF

Mixing, fusing and annealing costs of high-quality tempered cast iron. RUDOLF SRORZ. *Giesserei* 15, 905-11(1928).—A lecture. J. BALOZIAN

The behavior of cast iron under dynamic and static compression strains. BERNWARD GARRE. Tech. Hochschule, Danzig-Langfuhr. *Giesserei* 15, 792-3(1928).—Expts. were made to det. the vol. changes of cast Fe on rapid and on slow compression. A "quality Fe" (mostly pearlite), machine casting (more ferrite and graphite than in the previous), and ordinary cast Fe (with much more of these two constituents) was used. The tests show in each case that, up to the appearance of cracks, the force used is greater with rapid than with slow compression. The cracks are clearly visible on the exterior of the specimen when it is slowly compressed, while with rapid compression they are less distinct. The ratio of rapid to slow compression (dynamic/static) is greatest with pearlitic Fe, and decreases with decreasing content of pearlite. J. BALOZIAN

The gray nucleus of malleable cast iron. II. OT. QUADRAT AND J. KORITTA. *Chemický Obzor* 2, 178-82; *Chem. Zentr.* 1927, II, 971.—The object of the study was to det. the chem. compn. and the phys. properties of the material examd., and the effect of heat treatment. Compn. of the starting material: 2.5-2.95% C, about 0.8% Si, 0.08-0.18% Mn, 0.064-0.096% P and 0.049-0.078% S. After the tempering, at the surface a layer 1-2 mm. thick was found to be free from C. The gray nucleus contained 0.73-0.2% combined C as pearlite. Of the total C content, 98.5-96% was temper carbon. With decreasing C content of the gray nucleus of malleable cast iron, strength, ductility and reduction of area increased. With decreasing total C content, the strength of the gray nucleus increased. The Brinell hardness of the gray nucleus varied between 68 and 86. On cooling below 0° or heating to 100-300°, the mech. qualities deteriorated by 8-18%. The dissolving of the temper carbon and the deterioration of the mech. qualities connected with this began between 700° and 750°. Above 750°, an appreciable deterioration of the mech. qualities occurred, so that at 950° the strength was 50% of the original. Heating to 750° and cooling gave a pearlitic structure. On annealing 4 hrs. between a temp. of 900° and 600°, no decompn. of the pearlite occurred. G. SCHWOCH

The equilibrium diagram of the iron and iron sulfide system. KOZO MIYAZAKI. *Science Repts. Tôhoku Imp. Univ.* 17, 877-82(1928).—The equil. diagram of the Fe-FeS system was detd. by means of thermal analysis and elec. resistance measurements. The FeS was prepd. free from O by repeated melting of Merck's FeS with elementary S and subsequent solidification in a vacuum chamber. Samples weighing approx. 40 g each were put in a tubular crucible and melted under a cover of molten CaCl₂. The liquidus consists of two branches intersecting at the eutectic point of 83% FeS and at a temp. of 985°. DOWNS SCHAAR

Steel for casehardening—normal and abnormal steel. S. EPSTEIN AND H. S. RAWDON. Bur. of Standards. *Bur. Standards J. Research* 1, 423-66(1928).—That soft spots in casehardened articles may owe their origin to the kind of steel used, as claimed by McQuaid and Ehn (*C. A.* 16, 1730, 2291, 3460, 3850), has been exptly. confirmed. The characteristics of the so-called normal and abnormal microstructures of the extreme types and of the intermediate gradations are described. Normal steel carburizes somewhat more deeply than abnormal steel. Segregations of abnormality may occur. The mech. treatment seems to have no noticeable effect on the degree of normality. After certain heat treatments, especially annealing in H, abnormal steel assumes a more normal structure. On water-quenching abnormal steel is more prone to give soft spots. However, on quenching in brine or NaOH soln. abnormal steel, as well as normal steel, hardens without soft spots. Air or other gases ordinarily dissolved in quenching water may cause soft spots. After carburizing, the core of the abnormal steel, probably because of its finer grain, shows higher impact strength than the corresponding normal steel. High-carbon (tool) steels show features of normality and abnormality similar to those met in carburizing steels. Most cases of abnormality in com. steel seem to be associated with the use of Al for deoxidizing. Nothing arose in this work to controvert Ehn's theory that abnormality is due to dissolved oxides or, more probably, undissolved submicroscopic particles of oxide. The results of the spectrographic analyses for Al, deoxidation tests of com. steel with Al and ferrovanadium exams. of small test ingots taken during the progress of open-hearth heats, O and Al₂O₃ analyses, surveys for inclusions and thermal analysis—made in the study of the causes of abnormality—are described and discussed. ROBERT F. MEHL

The energizing action of carbonates contained in carburizing mixture. GENSKY TAKAHASHI. *Science Repts. Tôhoku Imp. Univ.* 17, 883-926(1928).—The mechanism of the action of the alkali and the alkaline earth carbonates when used with C in increasing the velocity of carburization of Fe and steel is shown by a series of expts. to be the

liberation of C from CO, the nascent C easily diffusing into Fe or steel, rather than by the reaction upon Fe and steel of CO formed by the reduction of the carbonates. The new theory is based on the following facts: (a) the carbonate seps. C from CO; (b) the velocity of carburization increases as the amt. of the nascent C coming into contact with the surface of Fe or steel increases; (c) the presence of any substance acting to produce free C from CO increases the velocity of carburization; (d) under the condition that the C liberated from CO easily recombines with CO₂, the energizing action of carbonate is not marked; (e) the energizing action of carbonate does not exist in an atm. contg. no CO; (f) active C easily diffuses into Fe and steel; (g) when Fe or steel is heated with C, the carburization is more energetic in the presence of the carbonate than in a brisk current of CO; (h) the carbonate increases the carburization velocity even when there is no disson. of it; (i) when the carburization is carried out in a current of CO, the presence of the carbonate remarkably accelerates the velocity of carburization, even in the absence of solid C; (j) the formation of CO by the direct reaction between the carbonate and solid C does not constitute the main factor of the energizing action of carbonate.

DOWNES SCHAAP

Causes of brittleness in carburized parts. STANLEY P. ROCKWELL. *Heat Treating and Forging* 14, 1026-8(1928).—An investigation was made of the causes of brittleness in case-hardened bolts and pins, and of the effect of a heavy blow as compared with numerous slight shocks in producing fracture. The carburized case is found to be the principal factor in creating core brittleness, this being present with a full case depth at carburizing temps. as low as 1500° F. Heat treatments, after carburizing, to give a core not showing brittleness, proved unsuccessful. Temps. at which the specimen is tested has great influence on brittleness. As little a difference as 30° F. (depending on the heat treatment and the compn. of the steel) between the annealing and fracturing temps. was a controlling factor between brittle and fibrous cores. Fracture tests show that bolts and pins, etc., broken after proper heat treatment, have either purely fibrous, or granular cryst. structures. Pieces having the first type of core break with an initial fracture of the case, followed by a bending of the core; those having the latter types break with a sudden snap, causing complete fracture. When frequent slight blows cause breakage of a bolt, granular cryst. and fibrous cores are in the same fractures.

J. BALOZIAN

The manufacture of steel pipes. EWALD RÖBER. *Stahl u. Eisen* 48, 1113-20 (1928).—The various methods for the manuf. of steel pipes are described and illustrated with graphs. The smallest and largest diams. obtainable with the various methods are given in form of tables. The methods are compared and their future is discussed.

J. A. SZILARD

The equilibrium diagram of the molybdenum-carbon system. TAKESHI TAKEI. *Science Repts. Tôhoku Imp. Univ.* 17, 939-44(1928).—An equil. diagram of the Mo-C system is proposed from data obtained by the microscopic examn. of melts made in an elec. furnace of sintered mixts. of Mo and C powders. The eutectic compn. is estd. to contain about 4% of C. The carbide sepd. by electrolysis from one of the specimens contained 5.5% C with a trace of Fe, and when examd. by the Debye-Scherrer x-ray method showed a hexagonal close-packed structure, its lattice const. varying with the C content.

DOWNES SCHAAP

The magnetostriction of a single crystal of nickel. YOSHIO MASHIYAMA. *Science Repts. Tôhoku Imp. Univ.* 17, 945-61(1928).—The longitudinal and transverse effects of magnetic elongation of a single crystal of Ni were observed for different orientations and different strength of fields of three oblate ellipsoids, whose flat planes coincided with planes (100), (110) and (111). The longitudinal effect is always contraction for all fields in all directions; the abs. amt. of contraction is largest in the direction (100), the next in the direction (110) and the last in the direction (111). The transverse effect is just the reverse of the longitudinal one. The variation of these effects with respect to the orientation of the ellipsoids is periodical under a constant field, the period being 90°, 180° and 60° for the planes (100), (110) and (111), resp.

D. S.

Etching phenomena on single crystals of copper. G. TAMMANN AND F. SARTORIUS. *Univ. Göttingen. Z. anorg. allgem. Chem.* 175, 97-120(1928).—The detn. of crystallite orientation by means of etching is studied and discussed, with particular reference to the etch figures obtained upon a ball consisting of a single crystal of Cu and having a diam. of 5.1 cm. Four types of etching were used: bright etching obtained with a 40-67% HNO₃ soln. contg. 20 g. CuCl₂ or 3 g. FeCl₃ per l. or a hot 100% KCN soln. and a 5% CuCl₂ soln.; acid etch such as that obtained with (NH₄)₂S₂O₈, 40% AcOH + 30 g. NaNO₃ per l., 1 part 37% HCl + 1 part 67% HNO₃ or 37% HCl + 40 g. CuCl₂ per l.; alkaline etch such as that obtained with 10% (NH₄)₂S₂O₈ + 10% NH₄OH,

or 1 mol. $\text{CuCl}_2 + 2.5$ mol NH_3 per l.; and finally etching with pptn. of another metal such as that produced by treatment with HNO_3 contg. HgNO_3 or AgNO_3 . The velocity of soln. of a crystal depends upon its orientation as well as upon the nature of the solvent and this leads to the production of etch figures, from which the no. and arrangement of crystallites can be detd.

Tin plate for cans for preserved goods. HERMANN SERGER. *Brunswick Res. Sta. for the Preserving Ind. Food Manuf.* 3, 481-2, 512, 513(1928).—The author discusses perforations, lacquer tests, pitting, graining and gassing. There is included a table giving the compn. of the iron for the manuf. of white plate so far recognized as optimum. The test for porosity in white plate is also given.

J. A. KENNEDY

Present position of the Röntgen technic and its practical application to cast materials. M. VON SCHWARZ. *Giesserei* 15, 883 9, 921-5(1928).—Numerous photographs of cast parts are given.

J. BALOZIAN

X-ray analysis of the silver-cadmium alloys. HALVDAN ÅSTRAND AND ARNE WESTGREN. *Metallog. Inst., Stockholm. Z. anorg. allgem. Chem.* 175, 90-6(1928).—The results of the recent x-ray study of the Cd-Ag alloys by Natta and Freri (*C. A.* 22, 1315) have been confirmed by the authors. These alloys are analogous in their structure to the Ag-Zn series. The following solid soln. phases have been identified in the order of increasing Cd content: α - has a face-centered cubic lattice, a_0 varying from 4.078 Å U. to 4.175 Å U.; β - crystallizes with a body-centered cubic structure, a_0 increasing from 3.323 Å U. to 3.327 Å U.; γ - has a complex body-centered lattice with 52 atoms in the unit cube, where a_0 changes from 9.935 Å U. to 9.982 Å U.; ϵ - exhibits a close-packed hexagonal structure, a_0 varying from 3.040 Å U. to 3.095 Å U. and c_0 remaining nearly const. at 4.810 Å U.; and η with the hexagonal structure of Cd- a_0 decreasing from 2.99 Å U. to 2.973 Å U.— c_0 increasing from 5.43 Å U. to 5.606 Å U. The alloy whose compn. has the formula AgCd undergoes a transition between 400° and 500°. The high-temp. form has a close-packed hexagonal structure, while the form stable at the low temp. shows the CsCl type structure. X-ray data do not indicate the appearance of a new phase at 200° as shown by thermal analysis.

A. J. KING

High-strength gold alloys for jewelry, and age-hardening phenomena in gold alloys. E. M. WISE. *Am. Inst. Mining Met. Eng., Tech. Publication No.* 147, 20 pp. (1928).—Phys. properties of a no. of modified Au-Cu-Ag alloys are given; the strength in the annealed and quenched states ranges between 59,100 and 82,600 lb. per sq. in. and the elongation varies between 32 and 61%. The yield point is greatly increased by age-hardening (an alloy composed of 38.5% Au, 12.3% Ag, 31.98% Cu, 1.84% Ni, and 15.38% Zn showed an increase in yield point from 34,100 to 99,400 lb. per sq. in. on aging at 325° for 30 mins. while the elongation in 2 in. dropped from 61½% to 55% in the same process). Tables and curves are included showing the Brinell hardness figures after annealing and aging for a series of Au-Ni alloys, 9.2-kt. green gold, 10 kt. yellow gold, 14-kt. white gold, and 18-kt. white gold alloys. Shot practice of alloying, melting and annealing and methods of controlling fire cracks in these alloys are described.

Alloys of calcium and aluminum. G. BOZZA AND C. SONNINO. *Giorn. chim. ind. applicata* 9, 443-50(1928).—The equil. of the system Al-Ca has been completed in the region of Ca = 0 to 5%. Low tensile and rapid increase in brittleness with even small

amts. of Ca seem to preclude the possibility of industrial uses for Al-Ca alloys.

A. W. CONTIERI

* Aluminum stock tanks compared with steel in corrosion tests. P. WAGNER. *Natl. Petroleum News* 20, No. 36, 50(1928).—Tests are being conducted by the Aluminum Co. of America and the Parkersburg Rig and Reel Co., to det. the relative corrosion of steel tanks and Al tanks.

M. B. HART

The production of cast rods of aluminum alloys which are dense and free of gas pores. WILLI CLAUS AND E. KALAEHNE. *Giesserei* 15, 996-1000(1928).—The influence of the method of fusion on the gas porosity of "Y" (1.5% Mg, 2.0% Ni, 4.0% Cu, 92.5% Al) and "American" (8% Cu, 92% Al) alloy castings was studied. The fusions were made by: (I) m. at 950°, holding at this temp. for 3 min. and pouring; (II) m. at 950°, holding for 3 min., cooling in air to 700° and pouring at this temp.; (III) m. at 950°, cooling in an elec. furnace to 680°, holding for 45 min., and pouring at 700°. In the molten condition, the alloys studied tended to form true solns. with the more easily diffusible gases. If the fused specimen was held at the m. p. for some time, degasification was complete. Fusing by III was found to give dense castings free of gas pores. Expts. with the "Y" alloy showed that: (1) with increasing velocity of solidification the d. of the metal increases; (2) with increasing velocity of cooling, the diams. of the gas pores increase, while their no. decreases. In chill castings the pores are microscopic, but evenly distributed throughout. Castings of the "American" alloy obtained by II, when retreated by III, were found to be dense and without pores, those obtained by III, when retreated by II, were again porous.

J. BALOZIAN

The properties of scleron metal. O. BAUER AND O. VOLLENBRUCK. *Mitt. Materialprüfungsamt Berlin-Dahlem*, Sonderheft 3, 78-88; *Chem. Zentr.* 1927, II, 2346. —Ingots (casting temp. 750°, mold temp. 280°) were examd. shaken and unshaken. Metallographically, no difference could be observed. From the analyses the conclusion may be drawn that scleron has a tendency to "inverse" ingot liquation. The metals added to the Al (Zn, Cu, Mn) are coned. mainly in the marginal layers and decrease towards the center. This liquation is generally not very important; it is most pronounced with Zn, Cu and Mn in the upper part of the ingot. The av. analysis of the pressed and refined bars was Si 0.35, Cu 3.14, Fe 0.49, Mn 0.72, Li 0.077, Zn 13.20%; the rest was Al. In the ground-mass consisting of mixed crystals of Al and Zn, small rounded crystals of a Cu-Al compd. (probably CuAl_2) were embedded. In 1% NaCl soln., scleron metal stands near to Al in the electromotive series; thus, in NaCl soln., it will behave similarly to Al. Scleron has high strength with good ductility. The modulus of elasticity is 722,000-755,000, the limit of stretching 3800-3814 kg./sq. cm., the limit of breaking 4842-4890 kg./sq. cm. The tensile strength is 10.98-11.1%, and the reduction of area 14.5-17.6%. It is easily worked by edge-tools and it also can be very highly polished.

G. SCHWOCH

New ways of using gases for soldering and welding. J. BRONN. *Chem. Fabrik* 1928, 569-70, 584-5. —With the spread of the practice of cooling and compressing coke oven gases, giving H-N mixts. on the one hand and CH_4 on the other, it is necessary to find ways of utilizing the CH_4 to better advantage. CH_4 has too low a velocity of combustion to give satisfactory results when used in soldering and welding app. By adding to it H_2 , with its high velocity of combustion, mixts. are obtained that yield very much better results. Comparative tests were run with H only, a mixt. of 73% H and 27% crude CH_4 , and a second mixt. contg. 37% crude CH_4 and 63% H. The first mixt. showed a saving of 46% in fuel, and the second of 67%, as compared with H only. About 25% of O also was saved, and 10% less time required for the operations. Such mixts. of CH_4 and H are superior to city gas for the purposes mentioned because they do not carry the inert N and low-value CO, and are free from the danger to workmen due to the CO. Nor do they cause injury because of S or tar content; the fact that they are cooled to -150 to -200° during sepn. insures against these and other impurities remaining in the gas. By adjusting the proportions of H and CH_4 , wide variations of temp., oxidizing and reducing properties, etc., can be secured; the flexibility is much better than with the oxy-acetylene flame. W. C. F.

The Jirotko dip process. A new process for improving light metals, especially aluminum. MARTIN MEIER. *Korrosion* 3, 33(1928).—*Cf. C. A.* 21, 222, 888.

J. H. MOORE

Rusting and protection of iron. M. SCHULZ-KIRCHMÖSER. *Intern. Congress Testing Materials* 2, 592-602(1927).—After discussing theories of corrosion and the methods of protecting iron against rust, S. takes up oil paints. Unpigmented oil films do not prevent corrosion. Red lead is the most effective pigment in preventing corrosion, being superior to red ochre and other substitute pigments. So-called "dispersion"

red lead is better than the ordinary variety in accelerated tests, in resistance to caking and settling and in brushing. Caking is less noticeable with pigments contg. a minimum amount of excess PbO. To prevent lead poisoning the removal of old paint coats is accomplished by means of a wet sand blast.

The use of cadmium, according to the Udylyte process, as a corrosion preventative. KARL GEBAUER. *Korrosion Metallschutz* 4, 201-4(1928).—A discussion of the method of obtaining Cd deposits on Fe according to the Udylyte process. In comparative tests Ni-plated Fe rusted after 316 hrs.; hot-dip galvanized Fe after 650 hrs. and sherardized Fe after 367 hrs.; Cd-plated Fe remained rust-free after 1860 hrs.

B. E. RÖRTHELI

Accelerated laboratory corrosion test methods for zinc-coated steel. EDWARD C. GROESBECK AND WM. A. TUCKER. *Bur. Standards J. Research* 1, 255-95(1928).—The simulated atm. and the salt-spray methods of testing the corrosion resistance of hot-dip galvanized steel sheet were compared. The atm. test consisted in exposing sheet test pieces in a chamber contg. a moist mixt. of SO₂ (1%), CO₂ (5%) and air (94%) for 5 hrs., 1 hr. under a water spray and 18 hrs. drying. This cycle was repeated until failure occurred as evidenced by rust. The salt spray test used a spray of NaCl or NH₄Cl. A consistent relationship between wt. of coating and life was found, the life being shorter in the atm. test. The atm. test gave uniform corrosion while the spray gave a localized type. No attempt was made to correlate the test life with actual results from exposure tests. The presence of 0.2% Cu in the base metal showed no appreciable effect on the life. The atm. test was concluded to be the more promising.

J. K. ROBERTS

Corrosion tests with copper steel under natural conditions. KARL DAEVES. *Stahl u. Eisen* 48, 1170-1(1928).—Corrosion tests conducted for 2½ yrs. near a dyeing plant, where the acid content of the air is high, with ordinary and Cu steel showed the superiority of the latter. After an exposure of 21 months, ordinary steel (0.03% Cu) showed a loss of wt. of 23%; Cu-alloyed steel (0.23% Cu) lost only 16%. The corresponding figures for galvanized steel and galvanized Cu steel are 12 and 7%, resp. For test pieces exposed for 18 months, the loss for galvanized steel was 28.1%, for galvanized Cu steel (0.15% Cu) 19.3%.

Metallurgy. HENNING G. FLODIN AND ÉMIL G. TORVALD. *Ger.* 467,146, Apr. 25, 1924. Metals, especially Zn and Pb, are extd. from their sulfide ores by metallic Fe. The ore and the Fe are finely divided, mixed, and inserted as a briquet into an elec. furnace.

Treating ores containing volatilizable metals. F. KRUPP GRUSONWERK A.-G. Brit. 287,745, May 24, 1927. In a process of treating ores such as described in Brit. 252,679 (*C. A.* 21, 2246), material such as lime, limestone, sand or KNO₃ is introduced into the reaction zone of the furnace for stiffening the charge or for its treatment; this permits increase of temp. in the reaction zone without fusing the charge.

Apparatus (with an endless track) for sintering ores. BETHUNE G. KLUGH (to American Ore Reclamation Co.). U. S. 1,690,231, Nov. 6.

Froth flotation. ALBERT W. HAHN. U. S. 1,690,225, Nov. 6. A pulp contg. ore such as Cu ore contg. Fe and Mn is subjected to the oxidizing action of bleaching powder in the presence of an alk. substance and oxides such as those of Fe and Mn are thus pptd. assocd. with values to be recovered, by changing them into higher oxides; a flotation agent such as xanthate and pine oil is then added and the material is subjected to froth flotation.

Froth flotation concentration. ROBERT E. PHELAN and SHERWIN P. LOWE (to R. H. Channing, Jr., agent). U. S. 1,690,907, Nov. 6. In sepg. micaceous and talcky

minerals from concentrates such as those of Cu ores starch is added to the ore pulp and the pulp is made non-alk. to prevent the minerals from entering the froth, and the pulp is then subjected to flotation.

Concentrating ores. EDWARD H. SNYDER and WM. D. GREEN (to Combined Metals Reduction Co.). U. S. 1,691,310, Nov. 13. Ores contg. at least one of the metals Ag, Pb or Cu are subjected to the dissolving action of an alk. thiosulfate and any of the metals dissolved are pptd. as sulfide from the resulting alk. soln.; the pptd. sulfide, any natural sulfides of the ore and any mineral particles to which a pptd. sulfide adheres are then sepd. from gang of the ore by froth flotation while regenerating the solvent by the action of the precipitant upon the ore soln.

Sluice-box for concentrating ores. J. F. DAY. Brit. 287,824, Dec. 8, 1927.

Thiocarbanilide solution. HAROLD GRAY (to B. F. Goodrich Co.). U. S. 1,690,166, Nov. 6. A soln. suitable for use as an *ore flotation reagent* comprises thiocarbanilide together with a plurality of amines including aniline, xyldine and dimethyl-*p*-phenylene-diamine.

Reducing oxide or oxide ores to metals. SIGURD WESTBERG. U. S. 1,690,916, Nov. 6. Oxides or oxide ores are heated with suitable carbonaceous material to a temp. sufficient to effect reaction and the CO formed during the reaction is used for the production of H by reaction with steam and the H is introduced into the reaction zone.

Smelting. ANTON SCHAUER and HERMAN FRITZ. Ger. 466,467, Dec. 12, 1926. A crucible is mounted on a circular rotary dish-shaped pan which catches the contents if the crucible cracks or overflows.

Iron smelting. RICHARD MOLDENKE (to New Process Multi-Castings Co.). U. S. 1,691,401, Nov. 13. In prepg. iron for pouring into molds, a charge is melted in a blast furnace, and the melt is poured into an elec. furnace and mixed with molten iron whose compn. has been regulated in accord with the finished compn. of the melt. An app. is described.

Reducing iron ores. STAALSYNDICAAT DR. LEDEBOER. Brit. 287,925, March 30, 1927. In reducing Fe ore and melting the Fe formed by the combustion of a gaseous fuel, a combustion gas is used which contains practically no O and is produced by the complete or practically complete combustion of the fuel by a surface combustion burner.

Apparatus (with rotating inclined horizontal cylinders) for solid reduction of metals such as iron from ores. JOHN W. HORNSEY (to Granular Iron Co.). U. S. 1,690,820, Nov. 6.

Magnetic apparatus for separating iron from slurry. MAGNET-WERK G.M.B.H. Eisenach, Spezialfabrik für Elektromagnet—Apparate. Ger. 465,620, Sep. 3, 1925.

Iron from oxide ores. GRANULAR IRON CO. Ger. 466,756, Feb. 27, 1925. The ore is first preheated in an inclined rotary drum and then reduced in a second similar drum, reducing agents contg. non-gaseous hydrocarbon being added to the ore entering the second drum and the temp. in both drums being maintained, suitably at 850–950°, so that a granular non-spongy product is obtained.

Reduction of oxides. JACQUES CHABANNAIS. Fr. 637,403, July 11, 1927. Oxides of metals or of metalloids such as As, Bi or Sb are reduced in an extremely fine state of division, such as the colloidal state.

Recovery of metals. ANACONDA COPPER MINING COMPANY. Fr. 638,638, July 21, 1927. Metals are recovered from slags and scoriae by injecting air and finely divided fuel in quantity greater than that which could be burnt by the air, and collecting the smoke. Metals such as Pb and Zn may be deposited from the smoke in sep. chambers.

Tin from ores. H. L. SULMAN and H. F. K. PICARD. Brit. 286,795, Dec. 13, 1926. In extg. Sn from ores contg. also other metals such as Fe, by chloridization and selective distn. of SnCl_2 , steam is admitted to the charge after the chloridizing step to decomp. unvolatilized chlorides and recover HCl. Numerous details are given and an app. is described.

Leaching of copper values in place. RICHARD F. GRANT, FRANKLIN B. RICHARDS and HERBERT E. WETHERBEI (one-fourth to Howard M. Hanna). U. S. 1,690,446, Nov. 6. A shaft and connecting drifts are driven to widen operations at a level below that of the surface water and localized trenches or containers are provided appurtenant to the underground workings; a soln. of $\text{Fe}_2(\text{SO}_4)_3$ of approx. 4% diln. is supplied above the drifted area of Cu ore and is permitted to percolate through the ore body, and surface water and precolating leaching soln. are pumped from the level of the drifts.

Chromium ores. I. G. FARBENIND. A.-G. (Paul Weise and Franz Specht, inventors) Ger. 467,212, Apr. 17, 1927. Cr ores are concd. by heating to over 100° with

kali hydroxide or carbonate in the absence of acid. The treatment may take place under pressure and the lye afterwards treated with dil. acid.

Zinc ores. SOCIÉTÉ GÉNÉRALE MÉTALLURGIQUE DE HOBOKEN. Fr. 638,922, cc. 30, 1926. Blende is heated with ZnSO_4 whereby ZnO and SO_2 are obtained. Cf. A. 22, 3965.

Reducing the cadmium content of zinc ore. OSCAR GERLACH and NILS OSTMAN (Matthiessen & Hegeler Zinc Co.). U. S. 1,691,714, Nov. 13. In order to remove Cd from O-contg. Zn ore, the ore is subjected to steam and to a quantity of reducing agent such as petroleum oil sufficient to reduce the Cd but not a material part of the Zn present in the ore, at a temp. (suitably about 980°) at which both Cd and Zn reduce.

Refining argentiferous metal. ALADAR PACZ. U. S. 1,691,207, Nov. 13. Molten metals such as Ag, Cu or their alloys are stirred with NaF or other alkali fluoride, to void blowholes when the metal solidifies.

Metallurgical furnaces. BENJAMIN TALBOT. Fr. 637,460, July 8, 1927. Improvements in the type of furnace of Brit. 235,346 are described (cf. C. A. 20, 807).

Cupola furnace construction. A. H. COPLAN. Brit. 288,072, July 18, 1927. The usual refractory lining is wholly or in part replaced by an inner steel wall spaced from the outer casing so as to form an air-heating chamber to the lower end of which air is admitted tangentially and from the upper end of which the heated air passes to the cylinders. Various details of the construction are described.

Ore-roasting furnace with superposed hearths. J. HARRIS. Brit. 287,356, June 1927.

Roasting-furnace with alternate rotary and fixed hearths. X. DE SPIRLET. Brit. 287,130, March 16, 1927.

Shaft furnace. HEINRICH RÜSENER. Ger. 466,627, Feb. 22, 1927. The casing at the top of a shaft furnace, specially a blast furnace, is protected by exchangeable riveted plates.

Furnace for melting and refining metals. WILHELM BUESS. Fr. 637,398, July 9, 1927. A gas or oil heated furnace suitable for melting and refining metals is capable of rotating through 360° and has its longitudinal axis at an angle to the axis of rotation.

Hearth furnace suitable for annealing. JOHN F. BAKER (to Westinghouse Elec. Mfg. Co.). U. S. 1,691,369, Nov. 13. Structural features of liquid and sand seals between the hearth and furnace walls are specified. The liquid seals are provided with cooling devices such as pipes carrying cooling fluid.

Furnace for annealing metals, etc. GEORGE F. BEACH (to F. J. Ryan & Co.). U. S. 1,690,710, Nov. 6.

Furnace for heat treatment of metals, etc. WM. L. SCHULENBERG. U. S. 1,690,555, Nov. 6.

Furnace for heating metal blanks. CHARLES F. OSGOOD (to Sullivan Machinery Co.). U. S. 1,690,428, Nov. 6.

Converters. RICHARD HELMS. Ger. 466,620, Sept. 5, 1926. In acid or basic converter beds some of the air channels are filled with iron rods or tubes to prevent remature destruction.

Apparatus for charging blast furnaces. P. B. HARWOOD. Brit. 287,865, March 8, 1927.

Apparatus for automatically shaping and grinding stones for blast furnaces. WILHELM KOSFELD. U. S. 1,691,898, Nov. 13.

Operating furnaces with powdered fuel. K. HUFSCHMIDT. Brit. 286,940, June 8, 1927. Primary air is injected in a direction tending to project the flame onto those parts of the furnace wall on which slag collects, and secondary air is normally injected at a lower level in a substantially opposite direction so as to repel the flame from these parts; the slag is melted at intervals by interrupting the secondary air supply and simultaneously introducing an addnl. supply at a higher level so as to allow the flame to act on the slag. Various details of construction are described.

Pickling metals. J. H. GRAVELL. Brit. 287,911, March 29, 1927. When foam-producing agents such as saponin, rye-meal liquor or cellulose pulp waste are added to acid pickling baths to prevent action of the acid on the cleaned metal, CH_2O or substances such as thioamides or substituted thioamides capable of generating CH_2O in the bath are used to protect the foam. Brit. 287,912 specifies the addn. of substances such as NH_4CNS which combine with nascent H and inhibit action of the acid bath on the cleansed metal.

Apparatus for centrifugal casting of metal articles. DAVID BROWN (to David Brown & Sons, Ltd.). U. S. 1,691,464, Nov. 13.

Molds for centrifugal casting of metal pipe. C. E. WILDER. Brit. 287,317, March 12, 1927.

Centrifugal casting apparatus for making articles such as bushings. JOHN O. WISHART. U. S. 1,690,354, Nov. 6.

Casting metal. VEREINIGTE STAHLWERKE AKTIENGESSELLSCHAFT. Fr. 637,578, July 13, 1927. A casting of superior quality is obtained by freeing the metal of gas or other non-metallic impurities in a rotating hearth or casting ladle.

Casting magnesium or similar metals. BRITISH MAXIUM, LTD. Brit. 287,164, March 18, 1927. Salts of NH_4 such as the borate or fluoride (suitably 2%) are mixed with or applied to the inner surface of sand molds to protect easily oxidizable metals such as Mg or its alloys which are cast in the molds. Agglomerants, solns. of resins in oils or other substances more readily oxidizable than Mg may also be added to the sand in prep. the mold.

Chilled iron rolls. H. E. WALTERS (to United Engineering & Foundry Co.). Brit. 287,396, March 23, 1927. Rolls are made by casting high-C iron contg. Cr and Mo and having a low S and P content in a chill mold. The metal contains C 2.75-4.0, preferably 3.0-3.75%, Si 0.50-2.50, preferably over 0.75%, Mn 0.15-1.50, preferably 0.20-0.80%, P under 0.20, preferably under 0.10%, S under 0.20, preferably under 0.10%, Cr 0.50-1.75, preferably 0.90-1.25%, Mo 0.05-2.00, preferably 0.15-0.80%. The Si should be sufficient to give the unchilled portion of the roll a gray or mottled iron structure. A roll thus made has a surface almost as hard as a cold roll contg. large quantities of C and S and there is no clear line of demarkation between the core and chilled surface.

Slag and gas eliminating apparatus for use in association with steel furnaces. FREDELLIA H. MOYER. U. S. 1,690,748, Nov. 6.

Apparatus for pouring molten steel. FREDELLIA H. MOYER. U. S. 1,690,749, Nov. 6.

Pouring molten steel. FREDELLIA H. MOYER. U. S. 1,690,750, Nov. 6. The metal is poured and received in an oxidizing atm., degasified in a nonoxidizing atm., and then teemed in an oxidizing atm.

Bessemer process for making steel. S. G. ALLEN. Brit. 286,745, Aug. 30, 1926. Especially in use of "non-Bessemer pig iron," the net blow heat required to bessemerize a charge of given characteristics is detd. and the O in the oxygenated blast is so proportioned that the required net blow heat is furnished. In treating an iron contg. 1% of P, the blast may contain 38% O.

Surface hardening of steel. GEORGES CHARPY. Fr. 638,913, Dec. 29, 1926. The surface of steel is hardened by heating to a temp. detd. for each steel (*e. g.*, between 600° and 675° for C steel) in the presence of solid, liquid or gaseous C compds., preferably not contg. O, such as cyanides or ferrocyanides.

Tempering of iron or steel. DEUTSCHE GOLD- UND SILBER SCHEIDE-ANSTALT. (vorm. Roessler.) Fr. 637,527, July 12, 1927. A tempering bath contg. cyanides with or without other salts, such as NaCl, soda, alkali or alk. earth cyanamides, is heated to temps. above 900°, and the production of foam is prevented by finely divided wood- or animal-charcoal. The surface of the bath is protected from the air by a layer of substances such as graphite which can react with the air. Cf. C. A. 22, 2351.

Plastic copper. GEBR. SIEMENS & CO. (Erich Birnbräuer, inventor). Ger. 466,515, Aug. 3, 1922. Addn. to 454,804. A finely divided Cu of high plasticity is prep. by pptn. of an oxidic ppt. from a Cu soln., and after washing with water, reducing with H at a temp. not above a dull glow, *e. g.*, 570°.

Condensation of zinc vapors. THE NEW JERSEY ZINC CO. Fr. 638,619, Aug. 1, 1927. Vapors of Zn are caused to travel through a no. of relatively long and narrow tubes so sloped that the condensed metal flows in the opposite direction to the vapor and a graduation of temp. is obtained along the tubes.

Zinc. THE NEW JERSEY ZINC CO. Fr. 638,960, Aug. 4, 1927. A vertical furnace for the reduction of zinciferous material is described in which the mass of material and reducing agent are heated through the metallic walls to a temp. not above 1150°.

Zinc. THE NEW JERSEY ZINC CO. Fr. 638,620, Aug. 1, 1927. Zinciferous materials are reduced by passing them, mixed with a reducing agent, through a reducing chamber heated sufficiently to volatilize the Zn but without scorification or fusion, the mass remaining porous throughout.

Protective oxide coating on ferrous metals. FRANKLIN B. RINCK (to Western Elec. Co.). U. S. 1,690,378, Nov. 6. Ferrous metal articles are subjected to an oxidizing atm. at a temp. (suitably about 760°) which is not materially lowered during

the process and the oxidizing character of the treating atm. is increased, *e. g.*, by supply of steam in increasing quantities.

Protecting ferrous metals from corrosion. T. E. MURRAY. Brit. 287,194, Nov. 8, 1926. The metal is coated with Ni, preferably electrolytically, and then heated to cause the Ni to alloy with the ferrous metal and form on the outside an adherent oxide coating. Before the heating, an addnl. coating of Cr may be applied and coatings of other metals such as Fe, Ni and Cr may be further applied and an adherent oxide coating produced in each case by heating.

Protecting magnesium and its alloys from corrosion. I. G. FARBERIND. A.-G. Brit. 287,450, March 19, 1927. The metal is treated with an acid soln. of a dichromate, and may then be coated with lacquer.

Protecting magnesium and its alloys from oxidation. G. MICHEL. Brit. 287,046, March 12, 1927. A modification of the process described in Brit. 249,484 (*C. A.* 21, 888) consists in coating the metal with a varnish mixt. having a base of synthetic resin and contg. free phenol. Cf. *C. A.* 22, 2917.

Apparatus for coating wire, bands, etc. WERNER & MERTZ A.-G. Ger. 466,842, Aug. 4, 1926. An endless loop of the material is reciprocated through a coating bath and through a plate made of material susceptible to warmth and friction. The size of the opening in the plate increases as the coating proceeds, and coating is continued until the size of the opening corresponds to the attainment of the desired depth of coating.

Coating articles of aluminum or its alloys. BOHUMIL JIROTKA. Ger. 466,843, Nov. 24, 1926. Mixts. of salts of Sn, Pb, Zn or other suitable metals with concd. solns. of alkali metal salts, preferably carbonates, are brushed on the articles at a raised temp., whereafter the coating is flame-treated. A suitable soln. contains K_2CO_3 (40 parts) and $SnSO_4$ (1 part).

Coating aluminum with zinc. B. JIROTKA. Brit. 286,729, March 10, 1927. Articles of Al or Al alloy are treated with solns. of Zn salts contg. also an alkali borate, *e. g.*, mixts. prepd. from NaCN, $ZnCO_3$ and borax or from $NaHCO_3$, $KHCO_3$, $ZnCO_3$ and borax.

Coating steel with lead and zinc. E. A. ATKINS and RYLANDS BROS., LTD. Brit. 287,201, Nov. 19, 1926. Steel wire or other steel articles to be coated after being immersed in molten Pb or a Pb alloy at 600-800° to effect annealing are then immersed in molten spelter or Zn without coming into contact with the atm.

Tin plates. AMERICAN SHEET and TIN PLATE CO. Brit. 287,436, Sept. 13, 1926. Tinned plates pass through a grease pot and thence by a conveyor to a washing vessel contg. hot Na_2CO_3 or other suitable alkali soln. An app. is described. Brit. 287,437 also relates to similar and assocd. app.

Tinned plates. H. WILLIAMS. Brit. 287,288, Feb. 9, 1927. Plates after passing through a tinning bath are passed through a water bath which may contain Ba phosphate, heated to about 100° so that any water adhering to the plates is rapidly evapd. The bath may be heated by tubes carrying superheated steam.

Apparatus for molding aluminum, bronze, etc. FIRMA CARL FELDHAUS. Ger. 466,835, Apr. 1, 1926. The mouthpiece of the mold extends through a bell-shape casing connected to a vacuum pump by which the molten metal is drawn from a bath into the mold.

Alloys. STANDARD TELEPHONES and CABLES LTD. & CO. Ger. 467,107, May 25, 1924. Alloys of phosphor-bronze and lead are used for making elec. contacts. The proportions may be 4-5½% Sn, 1-4% Pb, 0.5-0.25% P and the rest Cu.

Heat-resistant alloy. HARRY M. WILLIAMS. U. S. 1,690,352, Nov. 6. An alloy which is suitable for engine valve heads or valve guides comprises Fe together with C 2.5-3.0, Si 3.0-3.5 and P 1.90-2.25%.

Alloys of aluminum and beryllium. COMPAGNIE DE PRODUITS CHIMIQUES ET ELECTROMETALLURGIQUES ALIAS, FROGES ET CAMARGUE. Fr. 638,646, July 26, 1927. Alloys of Al contg. Be are improved mechanically by heating them to a temp. just below the fusion point of the most fusible constituent and afterwards tempering at this temp. With alloys contg. only Al and Bé they are heated to just below the eutectic point which varies from 550° to 645°. The alloys are afterwards aged at a temp. below 200°.

Copper alloys for coating iron or steel or use in welding or hard soldering. METALLBANK UND METALLURGISCHE Ges. A.-G. Brit. 286,616, March 5, 1927. Cu is alloyed with Ni 0.5-10 and Fe and Si (preferably as ferro-Si) 0.5-3%, with or without Mn 0.05-6%.

Alloys of copper and zinc. A. CORRADINI and SOC. METALLURGICA G. CORRADINI.

Brit. 287,369, July 1, 1927. Alloys suitable for use as a "substitute for bronzes" comprise Cu 50-60, Zn 30-40, Pb 0.25-1.5, Fe 0.25-1.5, Mn 2-6 and Ni 2-6%.

***Refractory iron alloys.** F. O. VOGEL and C. F. C. WEICHELT (trading as Meier & Weichelt). Brit. 287,876, March 28, 1927. Alloys free from self-hardening properties contain Ni 12-20, Cr 16-20, Si 0.3-3.0 and up to 1% of C and may also contain about 1% Mn.

Hardening iron containing alloying metals. F. KRUPP A.-G. Brit. 287,156, March 17, 1927. Articles of cast iron contg. one or more of the elements Al, Si, Mn, Cr, Ni, Co, V, Mo, W, Ti or Zr (e. g., about 1% of Al) are hardened on their marginal layers by heating at about 500° with substances liberating N.

Treating wire or strips of aluminum or aluminum alloys. SPEZIALFABRIK FÜR ALUMINIUM-SPULEN UND-LEITUNGEN GES. Brit. 287,503, March 22, 1927. Articles such as wires, plates or bands of Al or Al alloys are provided with an elastic insulating covering of oxide by treatment with oxidizing liquids or gases such as by an electrolytic bath and subjecting the articles during the treatment to mech. treatment such as hammering, beating, rubbing or bending. A bath may be used comprising org. acids such as oxalic acid or inorg. acids such as HNO₃ or chromic acid.

Recovering aluminum and magnesium and their alloys from scrap. I. G. FARBEN-IND. A.-G. Brit. 287,360, June 13, 1927. A modification of the process described in Brit. 182,948 (C. A. 16, 4180) and Brit. 219,287 (C. A. 19, 461) consists in using as the salt bath a mixt. of CaCl₂ and CaF₂ in such proportions that under the conditions of working a quantity of one or the other of the salts sufficient to act as an inspissating agent seps. out from the remaining eutectic mixt. which consists of CaCl₂ with about 18% of CaF₂.

Removing copper from alloys. H. HARRIS. Brit. 288,004, Feb. 21, 1927. Cu is removed from white metals and alloys such as silver lead, antimonial lead and tinny lead (which may or may not contain As), by treating the molten metal or alloy with S or a S-liberating material or gas such as H₂S in the absence of air or other oxidizing agents. Resin, pitch or other carbonaceous materials may be mixed with the metal during or after the treatment with S. The Cu sulfide dross formed is removed under non-oxidizing conditions.

Separating tin from alloys or mixtures. F. BISCHITZKY. Brit. 288,049, May 23, 1927. Sn is dissolved from its alloys or mech. mixts. such as lathe turnings, dross or the like by treatment with HCl contg. (as catalysts) dissolved salts which have no oxidizing action such as chlorides, sulfates, phosphates or borates, preferably salts which have a high ionization constant such as CaCl₂, Na₂SO₄ or MgCl₂. Fresh quantities of metal are treated with the used soln., effecting pptn. of Cu and Sb. The soln. is cooled to sep. Pb chloride and Sn oxide is pptd. from it by lime or chalk. The CaCl₂ thus formed may be further used in the process as a catalyst with HCl. Undissolved metallic residues may be exposed to air for oxidation which may be accelerated by adding alkali sulfides, Cu sulfide or V chloride, or by passing warm air, O or ozone over them. The residue is then dissolved in HCl which may contain CaCl₂ and the soln. is used to treat fresh quantities of metal. Co-pptd. Cu and Sb are washed from the undissolved granules, slightly calcined to form oxides and the Cu oxide may be selectively dissolved with HCl. Cf. C. A. 22, 3877.

Detinning tin scrap. TH. GOLDSCHMIDT A.-G. Ger. 466,904, Sept. 4, 1924. The scrap is passed through a series of chambers through each of which a current of Cl passes in a direction transverse to that of the scrap. The Cl current traverses the chambers in turn, and on leaving a chamber may be treated in known manner to regulate its temp. and concn. The scrap traverses the chambers in turn in the opposite order to the gas, and may be conveyed in trucks so constructed that their rear walls serve as partitions between the chambers.

Detinning. L. U. LA CORSA. Brit. 287,892, March 29, 1927. In detinning tinned scrap with a soln. of a ferric or stannic salt, the ferrous or stannous salt formed is regenerated by adding the anion of the used salt to the liquor to prep. it for reuse; e. g., when FeCl₃ or SnCl₄ is used Cl may be employed for the regeneration either as such or by use of a hypochlorite and HCl. When Fe₂(SO₄)₃ is used, SO₂ and O may be used for regeneration together with a catalyst such as N peroxide. Sn may be recovered from the soln. formed by electrolysis or pptn.

Punching and extruding process for producing tubes from metal billets. JOHN W. LEIGHTON. U. S. 1,691,725, Nov. 13. Mech. features.

Untarnishable metals. PETER PINKUS. Fr. 637,366, July 9, 1927. To render metals and alloys untarnishable and improve their color, specific addns. are made and in the order given. Thus, for soft Cu alloys, the Cu is melted and the following as

percentages are added: (A) 0.25 powd. CuSO_4 , (B) 2. calcined magnesite, (C) 1 powd. NH_4Cl , (D) 0.5 quick lime, (E) 1.25 tartaric acid, (F) 0.5 NaHCO_3 , (G) 1.25 tartaric acid. The other metals are added afterwards. For hard Cu alloys, the following percentages are used: (A) 0.5, (B) 4, (C) 3, (D) 1.5, (E) 2, (F) 1, (G) 1. The ingots are afterwards tempered in alum in water. For white metals and alloys the CuSO_4 is substituted by borax.

Apparatus for cutting metals by fusion with an oxyacetylene jet. A. GODFREY. Brit. 286,809, Dec. 21, 1926.

Annealing and tempering metal wire or strip. E. STRADA. Brit. 287,387, Aug. 10, 1927. Mech. features.

Uniting different metals. N. R. DAVIS and METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Brit. 286,823, Jan. 1, 1927. In joining metals such as Fe, steel, W or Mo to (or by means of) a metal of lower m. p. such as Cu, Ag or Au, the parts to be joined are heated by elec. currents induced peripherally in and adjacent their abutting surfaces by a high-frequency magnetic field. Numerous details and modifications are given.

Composition for use in welding. IRA FREEMAN U. S. 1,691,388, Nov. 13. A compn. suitable for use as a flux in welding cast iron is formed from a dry mixt. of equal parts by vol. of borax, powd. charcoal and plaster of Paris and Na silicate soln. as a binder.

Welding metals. C. L. IPSEN (to British Thomson-Houston Co., Ltd.). Brit. 287,528, March 23, 1927. Fusible electrodes or welding rods for arc or gas torch welding or C or W electrodes are wet with a liquid such as MeOH which is subsequently vaporized and may be dissoed, to improve the weld or assist in maintaining the arc. An app. is described.

Solder for aluminum. OSKAR SPENGLER (to I. G. Farbenind. A. G.). U. S. 1,691,532, Nov. 13. An alloy is used comprising Al 85-95 and Si 5-15%.

Solder for aluminum. VICTOR NICOLAS PROSPER-POI, RENARD. Fr. 637,633, Nov. 16, 1926. A solder for Al and its alloys contains 90 parts of Zn, 4 of Cu and 6 of Al.

Soldering aluminum. MAX DE ZERBONI DI SPOSETTI, LÉON WOLF and HENRI MARTINEK. Fr. 637,319, May 23, 1927. A compn. for soldering Al alone or to other metals such as Fe, Cu, brass, Zn, Sn or Pb is made by melting together brass 0.075 to 0.125 g., Al 0.15 to 0.2 g., Pb 0.5 to 0.6 g., Zn 0.05 to 0.095 g., Sn 1 kg., the metals being added to the melt in this order.

Soldering nickel or its alloys. PAUL ODAM. Fr. 638,873, Dec. 23, 1926. A flux composed of a mixt. of H_3BO_3 and alk. earth borates (borocalcite, voracite, etc.) and finally alkali borates is used.

Flux-cored solder tube. JOHN P. ERICH (to Chicago Solder Co.). U. S. 1,690,534, Nov. 6. Structural features.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Chemical synthesis one hundred years after that of urea. F. CARELLI. *Notiz chim. ind.* 3, 633-7(1928).—A review of the progress of organic synthesis from the production of urea by heating NH_4CNO to the latest syntheses by catalytic processes.

A. W. CONTIERI

Steric hindrance. LUDWIG ANSCHUTZ. *Z. angew. Chem.* 41, 691-6(1928).—A. gives a survey of the investigations on steric hindrance and discusses the different theories thereon. Numerous references are given.

G. SCHWOCH

Generalities on the derivatives of semi-saturation of the erythrene derivatives. CHARLES PREVOST. *Bull. soc. chim.* 43, 996-1018(1928); cf. *C. A.* 22, 2737.—P. suggests that in the semi bromination of erythrene only the 1,2- (racemic) and *trans*-1,1 dibromides are formed. There is no evidence of *cis-trans* isomerism of the γ -form. With decreasing mobility of the added radical the α - and γ -isomers are either desmotopes or mesomers. They show abnormal double decompn. and yield 3 isomers. Desmotropy is reached by the dibromides but the equil. between the α - and γ -forms is attained only very slowly. At low temp. the desmotropy of the dibromides corresponds to a pseudomer, since the *trans*-form predominates. The α -forms can be stable only when they are solids. The diacetins, diethylenes and glycols are mesomers at room temp. 200 g. of *trans*- $\text{MeCHBrCH:CHCH}_2\text{Br}$ is heated for 30 hrs. at 80° in 1 l. of H_2O contg. 100 g. of Na_2CO_3 . The resulting product after 500 cc. had been distd. off, contains 15% $\text{MeCH:CHCH(OH)CH}_2\text{OH}$ (I), b_{12} 107° , 70% $\text{MeCH(OH)CH:CHCH}_2\text{OH}$ (II), b_{12} 126° , and 15% of the *dl*-forms of $\text{MeCH(OH)CH(OH)CH:CH}_2$ (III), b_{12}

88-90° and 93-5°. Heating 200 g. of a mixt. of 1,2-, 1,4- and 3,4-methylethyrene dibromides (IV) with H₂O gives 20% I, 55% II and 25% III. The first distillate obtained contained MeCH₂CH:CHCHO as detd. by its semicarbazone. A small quantity of what may be a mixt. of MeCH:CHCH:CHBr and CH₂:CHCH:CHCH₂Br (V), b₁₀ 33-4°, n_D 1.5205, d₄ 1.335, is obtained from the original distillate. To IV refluxed under 20 mm. an equiv. quantity of quinoline is added dropwise. A mixt. of a mono- and a dibromide is collected. The monobromides consist of V and possibly a small quantity of MeCH:CHCH:CHBr. V with Br₂ gives CHBr(CHBrCH₂Br)₂, m. 150°.

D. H. POWERS

Method for the preparation of nitro- and chloronitroolefins. ERICH SCHMIDT AND GUSTAV RUTZ. Bayer. Akad. Wissenschaften München. Ber. 61B, 2142-8 (1928).—For the prepn. of nitro- and nitrochloroolefins were chosen the easily available acyl derivs. of the corresponding alcs., prepd. by condensation of MeNO₂ with aldehydes; these esters, heated several hrs. in Et₂O with KHCO₃, decomp. with remarkable ease according to the following equations (R = acyl): RCH(OR)CH₂NO₂ = RCH:CHNO₂ + ROH; RCH(OR)CHClNO₂ = RCH:CClNO₂ + ROH. To be sure the yields of the propylenes are considerably reduced because of their tendency to polymerize but with the higher homologs the yields are uniformly satisfactory. The 1st member of each series is characterized by its penetrating odor and its especially violent irritating action on the eyes; all the homologs are yellow. The decrease in the tendency to polymerize with increasing mol. wt. is less marked in the nitrochloro than in the nitro series. Since the nitroallyl of Askenasy and Meyer and of Henry is described as a colorless liquid and none of the characteristics of S. and R.'s isomeric compd. are mentioned, the *nitropropylene* (I) structure assigned by S. and R. to their own product is confirmed. All the other compds. prepd. by this method are likewise assigned the $\Delta^{1,2}$ -structure, which agrees well with their properties (color, irritant action, tendency to polymerize, mol. refraction of the olefins themselves (marked exaltation) and of their dibromides (normal values)). Substitution of the H in the C:CHNO₂ group by Cl apparently results in a depression of the exaltation of the refraction. *1-Nitro-2-propanol acetate* (28.2 g. from 24 g. of the alc. with AcCl in CHCl₃), b₈ 94-5°, n_D²⁰ 1.4242, d₄²⁰ 1.1588. *1-Chloro-1-nitro-2-propanol acetate* (92% yield), b₉ 90-1°, n_D²⁰ 1.4391, d₄²⁰ 1.2773. *1-Nitro-2-butanol acetate* (95%), b₁₁ 105-6°, n_D²⁰ 1.4285, d₄²⁰ 1.1224. *1-Chloro-1-nitro-2-butanol* (82% from the Na salt of the nitro alc. in Et₂O suspension with Cl), b₈ 97-8°, n_D²⁰ 1.4548, d₄²⁰ 1.2827; *acetate* (85%), b₁₂ 98-9°, n_D²⁰ 1.4429, d₄²⁰ 1.2376. *1-Nitro-2-pentanol acetate* (80%), b₁₀ 111-3°, n_D²⁰ 1.4339, d₄²⁰ 1.0898. *1-Nitro-2-octanol acetate* (94%), was at once worked up into the octylene. *1-Chloro-1-nitro-2-octanol* (70%), b₉ 140°, n_D²⁰ 1.4570, d₄²⁰ 1.1174; *acetate* (87%), at once worked up into the octylene. *1-Nitro-1-propylene* (44%), stable when pure but shows a great tendency to polymerize, especially in the presence of alkalis, b₁₀ 37°, n_D²⁰ 1.4527, d₄²⁰ 1.0661; *polymer*, yellow-brown odorless solid, almost insol. in H₂O and most org. solvents but sol. in NaOH; *dibromide* (70%), b₁₅ 97-9°, n_D²⁰ 1.5228, d₄²⁰ 2.0303. *1-Chloro-1-nitropropylene* (57%), b₁₂ 51-2°, n_D²⁰ 1.4759, d₄²⁰ 1.2840. *1-Nitro-1-butylene* (70%), b₁₂ 55°, n_D²⁰ 1.4532, d₄²⁰ 1.0251; *dibromide* (75%), b₁₂ 99-100°, n_D²⁰ 1.5181, d₄²⁰ 1.8857. *1-Chloro-1-nitrobutylene* (73%), b₁₀ 57-8°, n_D²⁰ 1.4728, d₄²⁰ 1.2143. *1-Nitro-1-amylene* (76%), b₁₂ 69-70°, n_D²⁰ 1.4550, d₄²⁰ 0.9952. *1-Nitro-1-octylene* (83%), b₉ 112°, n_D²⁰ 1.4596, d₄²⁰ 0.9476. *1-Chloro-1-nitro-1-octylene*, b₉ 110-1°, n_D²⁰ 1.4700, d₄²⁰ 1.0685.

C. A. R.

The preparation of hexamethylenetetramine on a factory scale. F. CHEMNITZ. Chem.-Ztg. 52, 735(1928).—The reaction 6HCHO + 4NH₄OH = (CH₂)₆N₄ + 10H₂O takes place almost quant. under proper exptl. conditions. An excess of NH₄OH must be maintained; otherwise NMC₃ will be formed, rendering the product unfit for use. The reaction is conducted in absorption flasks of 250 l. capacity. Into each flask is charged 180 kg. of 30% HCHO contg. 1-2% of MeOH, and then gaseous NH₃ is led in slowly for about 12 hrs. Approx. 22 kg. of NH₃ is used per flask. The temp. must be held below 20° by regulating the speed of NH₃ feed and by using cooling water around the reaction flasks. Flasks are arranged in parallel (usually 10 at a time) so that they can be charged and emptied in regular sequence. The product is filtered with animal charcoal, evapd. in vacuum pans, with addn. of fat to prevent foaming, and allowed to cryst. in enamel vessels overnight. Each 100-kg. lot of damp crystals is treated with 300-400 g. of 25% NH₃, centrifuged, washed with distd. H₂O, dried at 50° and sieved. The yield is about 96% of the theoretical, based upon the HCHO used.

W. C. E.

New organic salts of telluric acid. FREDERICK R. GREENBAUM. Dermatological Res. Lab., Phila., Pa. *Am. J. Pharm.* 100, 630-5(1928).— H_2TeO_4 combines readily with org. bases forming org. salts of H_2TeO_4 as follows: *Hexamethyleneamine tellurate*.—4 g. of H_2TeO_4 (1 mol.) is dissolved in 25 cc. of H_2O , 2.8 g. of hexamethyleneamine dissolved in as little H_2O as possible, and the latter added to the first soln. The resulting ppt. was filtered and redissolved in H_2O , acetone was added, then filtered, washed with alc., and acetone and dried in a vacuum desiccator. The compd. obtained represents a white powder, slightly sol. in H_2O and insol. in all org. solvents. On reduction with $\text{Na}_2\text{S}_2\text{O}_4$ or with NaHSO_3 black metallic Te is pptd. *Urea tellurate*.—3 g. of urea was dissolved in a small quantity of H_2O and added to a soln. of 6.6 g. of H_2TeO_4 dissolved in hot H_2O . After cooling, EtOH and ether were added and beautiful, shining crystals were obtained, which were filtered and washed with alc. and ether and dried in a vacuum desiccator. Urea tellurate forms white, shining needles, easily sol. in cold and warm H_2O , insol. in alc., ether and CHCl_3 and all other org. solvents. The aq. soln. has a slight acid reaction, showing that only 1 of the two hydrogens of the H_2TeO_4 is in combination with the urea. Reducing substances ppt. metallic Te. *Thiourea tellurate*.—7.6 g. of thiourea was dissolved in warm MeOH, allowed to cool and 13.5 g. of H_2TeO_4 in H_2O was added to the soln. After several hrs. of standing, a white ppt. was formed, filtered off, washed with cold H_2O and dried in a vacuum desiccator. Thiourea tellurate is a white powder, which is entirely insol. in acids, in cold and hot H_2O , sol., however, in alkalies, such as warm NaOH or KOH. Its soly. in alkalies makes this compd. available for therapeutic use. *Piperazine hydrate tellurate*.—1.6 g. of piperazine hydrate and 5.3 g. of H_2TeO_4 , each in hot H_2O , were combined. MeOH and acetone were added, which pptd. out the insol. piperazine tellurate. This was filtered, washed with H_2O , alc., acetone and ether and dried. The compd. is insol. in cold H_2O and in org. solvents, somewhat sol. in hot H_2O and is sol. in dil. alkalies. The soly. in alkalies indicates the presence of free uncombined H of H_2TeO_4 . W. G. GAESSLER

Synthesis of acetoin and its two homologs and their odor. TUNETO HIGASHI AND SUEKICHI MARUYAMA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 940-7; *Eng. Ed.* 1, 91-2(1928).—Acetoin, $\text{MeCOCH}(\text{OH})\text{Me}$, has been synthesized (1) from MeCOEt through $\text{MeCOC}(\cdot\text{NOH})\text{Me}$ and MeCOCOMe ; (2) by direct hydrolysis of MeCOCHBrMe , and (3) from MeCOCHBrMe through the acetate. In the 3 cases the odor of the acetoin is a very faint agreeable one, which does not resemble that of Japanese "saké." This shows that acetoin, though present in the fermentation products, has not much influence on the saké flavor. Two homologs of acetoin, viz., acetol and acetylethylcarbinol, were prepd.; their odor was substantially the same as that of acetoin.

A. L. HENNE

Vaccenic acid, a new fatty acid in beef, sheep and butter fat. S. H. BERTRAM. Tech. Hochschule, Delft. *Biochem. Z.* 197, 433-41(1928).—A method for prepn. is described in detail. It is a $\Delta^{11,12}$ -elaidic acid, $d_{20} 0.85601$, $n_D 1.43834$, $n_D 1.44071$, $n_D 1.44674$. The m. p., solidification point, I_2 no., etc., vary somewhat depending upon the source of the fatty acid. Consult original for details.

S. MORGULIS

The α -glucoheptulose and the α -glucoheptulitol. GABRIEL BERTRAND AND GEORGES NITZBERG. *Bull. soc. chim.* 43, 1019-23(1928); cf. *C. A.* 22, 2740, 3633.—B. and N. study the chem. properties of α -glucoheptulose (I), prepd. by the action of a culture of the bacteria from sorbose with yeast added to α -glucoheptitol. I gives the color changes with orcinol, phloroglucinol and resorcinol in the presence of dil. HCl, indicating the presence of a ketone group, and shows no oxidation with Br_2 . I with Na-Hg in H_2O gives the α -glucoheptulitol previously described. It is suggested that I has either the formula

D. H. POWERS

Hydroxyamino compounds which show the biuret reaction. IV. Anhydride formation by γ -amino- β -hydroxybutyric acid. MASAJI TOMITA AND TOMOKICHI FUKAGAWA. *Med. Acad. Nagasaki. Z. physiol. Chem.* 178, 302-5(1928); cf. *C. A.* 21, 3892.—When $\text{H}_2\text{NCH}_2\text{CH}(\text{OH})\text{CH}_2\text{CO}_2\text{H}$ is esterified with MeOH or EtOH and the ester HCl salt treated with NaOMe to liberate the free base, a ring closure to 70% γ -hydroxy- α -pyrrolidone occurs. The product is isomeric with the β -hydroxy- α -pyrrolidone obtained by Fischer and Göddertz (*C. A.* 5, 700) from the isomeric H_2 -

$\text{NCH}_2\text{CH}_2\text{CH}(\text{OH})\text{CO}_2\text{H}$. When refluxed with $\text{Ba}(\text{OH})_2$ it reverts to the hydroxy-amino acid. The latter gives the biuret reaction but the pyrrolidone does not.

A. W. DOX

Remarks on the paper by A. Weissberger: "Dipolar momentum of symmetrical compounds and *cis-trans*-isomerism with simple linkages." R. ENGELAND. Biochem. Inst. Mittelasiatischen Staatsuniversität. *Physik. Z.* **29**, 626(1928).—W.'s hypothesis (C. A. **22**, 3089) explains the existence of 2 Cu salts of bis- α -imino acids and the similarity between the Cu salts of *dl*- and optically active α -amino acids. A. L. HENNE

Action of anhydrous chloral on the amino alcohols and the hydroxyamino esters with a tertiary amine grouping. E. FOURNEAU AND M. L. E. W. BRYDOWNA. Pasteur Institute. *Bull. soc. chim.* **43**, 1023-7(1928).— CCl_3CHO (I), mixed with $\text{Me}_2\text{NCH}_2\text{-CMeEtOH}$ evolves a large quantity of heat. The product decomps. on vacuum distn. and recombines in the receiver to form $\text{Me}_2\text{NCH}_2\text{CMeEtOCH}(\text{OEt})\text{CCl}_3$; *HCl salt*, m. 128-30° (decompn.); *Bz deriv. of HCl salt*, m. 196-8° (decompn.); *Ac deriv. of HCl salt*, m. 193°; *Ac deriv.*, b. 158 60°. I with $\text{Me}_2\text{NCH}_2\text{CMe}(\text{OH})\text{CO}_2\text{Et}$ gives the ring compd. $\text{Me}_2\text{NCH}_2\text{CMe.O.CH}(\text{CCl}_3)\text{O.CO}$, (II), b₂₂ 140-2°, m. 66-7°; *HCl salt*,

m. 180-6°. The Pr ester with I gives II.

D. H. POWERS

The action of erepsin and of trypsin-kinase on *l*-leucylpentaglycyl-*l*-tryptophan. EMIL ABDERHALDEN AND HANS SICKEL. *Fermentforschung* **10**, 91-4(1928); cf. C. A. **22**, 2576.—*d*- α -Bromoisocapronyltetraglycylglycine (I), decomps 210°, $[\alpha]_D^{20}$ 12.21°, was prep'd. by Fischer's method (*Ber.* **39**, 2893) and chlorinated by treatment with PCl_5 . The reaction was incomplete, since the product contained only 41% of the calcd value for Cl. An attempt to couple the crude chloride with *l*-tryptophan Me ester in CHCl_3 , then to sapon. and replace the Br by NH_2 and finally isolate the desired heptapeptide through the Hg compd. entailed so great a loss of material that the prep'n. was abandoned in favor of the Schotten-Baumann procedure. The chloride was therefore shaken with *l*-tryptophan and *N* NaOH and the reaction product ppt'd. along with non-chlorinated I by addn. of *N* HCl. The crude product was sealed in a tube with liquid NH_3 and kept 6 days at 20-2°. From the residue after evapn. of the NH_3 the NH_4Br was ext'd. by abs. EtOH and the heptapeptide dissolved in H_2SO_4 and ppt'd. by HgSO_4 . The pptd. was decomp'd. by H_2S , the filtrate treated with $\text{Ba}(\text{OH})_2$ to remove H_2SO_4 , and evap'd. *in vacuo* at 40°. The residual *l*-leucylpentaglycyl-*l*-tryptophan is sol. in H_2O , AcOH and dil. EtOH, insol. in other org. solvents, sol. in acids and alkalies, ppt'd. by HgSO_4 and by phosphotungstic acid, and salted out of H_2O by $(\text{NH}_4)_2\text{SO}_4$. It gives a strong red biuret reaction, decomps. 175°, $[\alpha]_D^{18}$ 12.3°. Both erepsin and trypsin-kinase hydrolyze this heptapeptide, the former without and the latter with liberation of tryptophan. If, as Euler and Waldschmidt-Leitz have suggested, erepsin attaches itself to the free NH_2 group and trypsin to the carboxyl of polypeptides, the above observation would indicate that the 1st amino acid to be broken off from a polypeptide chain is the one to which the enzyme complex attaches itself. A. W. DOX

The influence of pepsin and of trypsin-kinase on polypeptides containing *d*-glutamic acid. EMIL ABDERHALDEN AND ERNST ROSSNER. Univ. Halle. *Fermentforschung* **10**, 95-101(1928).—*d*- α -Bromoisovaleryl-*l*-leucylglycyl-*d*-glutamic acid, $[\alpha]_D^{20}$ 16°, was prep'd. in 78% yield by coupling *l*-leucylglycyl-*d*-glutamic acid with *d*- $\text{Me}_2\text{CHCHBrCOCl}$ in the presence of *N* NaOH. It sep'd. as an oil when the reaction mixt. was acidified but was finally obtained in solid form by rubbing with petroleum ether and Et₂O and evap'd. *in vacuo*. It was converted into *d*-valyl-*l*-leucylglycyl-*d*-glutamic acid (I), $[\alpha]_D^{20}$ 11.4°, in 60% yield by 5 days' contact with 25% NH_4OH . The Br was removed by Ag_2SO_4 , the H_2SO_4 by $\text{Ba}(\text{OH})_2$, the NH_3 by evapn. and the excess Ba by H_2SO_4 , and the final product obtained by pptg. the MeOH soln. with Et₂O. It is amorphous and hygroscopic and may be salted out of H_2O by $(\text{NH}_4)_2\text{SO}_4$. *d*- α -Bromopropionyl-*d*-valyl-*l*-leucylglycyl-*d*-glutamic acid, $[\alpha]_D^{20}$ -18.2°, was prep'd. in 50% yield by coupling I in NaOH with *d*- MeCHBrCOCl , and the oily product purified by stirring with sat'd NaCl soln., extg. with EtOH, pptg. with Et₂O and drying *in vacuo*. By the same treatment as used for I, this was converted into *d*-alanyl-*d*-valyl-*l*-leucylglycyl-*d*-glutamic acid (II), $[\alpha]_D^{19}$ -10.7°, in 85% yield. Its properties are similar to those of I. By coupling II with *d*- $\text{Me}_2\text{CHCH}_2\text{CHBrCOCl}$, 65%, *d*- α -bromoisocapronyl-*d*-alanyl-*d*-valyl-*l*-leucylglycyl-*d*-glutamic acid, $[\alpha]_D^{21}$ 12.6°, was obtained, and the substance purified by stirring with H_2O , dissolving in a small vol. Et₂O and pptg. by adding more Et₂O. Amination and purification as with I and II yielded 75% *l*-leucyl-*d*-alanyl-*d*-valyl-*l*-leucylglycyl-*d*-glutamic acid (III), $[\alpha]_D^{20}$ -9.5°. The hexapeptide resembles I and II in its solubilities,

but is not hygroscopic, is salted out of H_2O by $NaCl$, and the ppt. obtained with phosphotungstic acid is less sol. in excess of reagent. It gives a carmine-red biuret reaction. Its $PhNCO$ deriv. (IV) is an amorphous powder sol. in $MeOH$, $EtOH$ and alkali, almost insol. in H_2O , Et_2O and C_6H_6 . Erepsin hydrolyzes III but not I and II, and trypsin-kinase attacks all 3 polypeptides. IV is attacked by trypsin-kinase but not by erepsin.

A. W. DOX

Dioximes. L. G. PONZIO. Reale Politecnico, Torino. *Gazz. chim. ital.* 58, 329-44(1928).—See C. A. 22, 4120.

C. C. DAVIS

Supplementary studies on the nitrile esters of the dicarboxyglutaconic acid. YOSHIVUKI URUSHIBARA. *Bull. Chem. Soc. Japan* 3, 219-26(1928).—The condensation of $EtOCOC(CN):CHOEt + HCNa(CN)CO_2Me$ (reaction A) should give $EtOCOC(CN):CHCNa(CN)CO_2Me$, while the condensation of $MeOCOC(CN):CHOEt + HCNa(CN)CO_2Et$ (reaction B) should give $MeOCOC(CN):CHCNa(CN)CO_2Et$, but (A) carried out in $EtOH$ gives exclusively di-Et dicyanoglutaconate semihydrate, m. 184° ; (A) carried out in $MeOH$ gives Me Et dicyanoglutaconate semihydrate, m. 197° , with the position of the Me and Et unknown, since (B) in $EtOH$ gives the same product. (B) in $MeOH$ gives only di-Me dicyanoglutaconate semihydrate, m. 224° . $CH_2(CO_2Me)_2$ condenses with di-Et ethoxymethylenemalonate: the Na deriv. is treated with dil. HCl , yielding the free ester; when the condensation occurs in $EtOH$, the final product is the Me tri Et ester, while it is the di-Me di-Et ester in $MeOH$. The constitution of the Na derivs. of the nitrile esters of dicarboxyglutaconic acid, and the mechanism of the condensation of an ethoxymethylene compd. $EtOCH:CHXY$ with a methylene compd. CH_2XY in the presence of $NaOEt$ are discussed.

A. L. HENNE

Ethyl 1,2,3,6-tetracarboethoxy-5-methoxy- $\Delta^{2,5}$ -cyclohexadiene-1-acetate, a derivative of triethyl aconitate. YOSHIVUKI URUSHIBARA. Tokyo Univ. *Bull. Chem. Soc. Japan* 3, 217-9(1928).—U. tried to methylate tri-Et aconitate (I) by refluxing it with 1 mol. of $EtONa$ and an excess of MeI in abs. alc., then heating under pressure at $115-20^\circ$. An oil was obtained b.p. $225-30^\circ$; a combustion and a mol.-wt. detn. indicated the formula $C_{22}H_{32}O_{11}$. To explain the reaction, it is assumed that 2 mols. of I split 1 mol. alc. and that 1 H is substituted by Me. Thus, I gives II, ($R = CO_2Et$), or its Na deriv., II is methylated to III (for which the name appearing in the title is proposed). III does not dissolve in aq. KOH , gives no color with $FeCl_3$, and does not condense with $PhNHNH_2$; these facts suggest that the Me group in III is in a MeO group and that II reacted in the enolic form to give III.

A. L. HENNE

The chemistry of the Jaffe's reaction for creatinine. V. The isolation of the red compound. ISIDOR GREENWALD. Harriman Research Lab., Roosevelt Hosp., N. Y. *J. Biol. Chem.* 80, 103-6(1928); cf. C. A. 22, 2925.—The compd. responsible for the red color in Jaffe's reaction for creatinine is made up of 1 mol. of creatinine, 1 of picric acid, and 2 of $NaOH$. It may be regarded as a compd. of the red tautomer of creatinine puerate with 2 mols. of $NaOH$. The red tautomer is pptd. from a fairly concd. soln. of the new compd. by HCl .

A. P. LOTHROP

Ureides of the bromovaleric acids. III. Influences on the physiological properties of the migration of the halogen in the acid chain. E. FOURNEAU AND G. FLORENCE. *Bull. soc. chim.* 43, 1027-40(1928); cf. C. A. 22, 3227.—The ureides of the isomeric bromovaleric acids are prepd. and their partition coeffs. and hypnotic actions studied and compared. $PrCHBrCOCl$ with $CO(NH_2)_2$ (I), gives $PrCHBrCONHCONH_2$ (II). $EtCHBrCH_2COCl$ with I gives $EtCHBrCH_2CONHCONH_2$ (III), m. 184° . $MeCHBrCH_2CH_2COCl$ with I gives $MeCHBrCH_2CH_2CONHCONH_2$ (IV), m. $160-1^\circ$. The uride could not be isolated from $CH_2Br(CH_2)_3COCl$ and I. $MeCEtBrCOCl$ with I gives $MeCEtBrCONHCONH_2$ (V). $MeCH:MeCO_2H$ with HBr at 0° gives $MeCHBrCMeHCO_2H$, m. $66-7^\circ$. Converting to the acid chlorides with 5 moles of $SOCl_2$ and treating with I gives $MeCHBrCMeHCONHCONH_2$ (VI), m. $125-6^\circ$. $CH_2BrCEtHCOCl$ with I gives $CH_2BrCEtHCONHCONH_2$ (VII), m. 108° .

$CH_3CH_2CHMe.CO.O$ with PCl_5 gives a good yield of $CH_2BrCH_2CMeHCOCl$, b.p. 128° . This acid chloride with I gives 30% $CH_2BrCH_2CMeHCONHCONH_2$ (VIII), m. 117.5° . The partition coeffs. between oil and water for the ureides II, III and IV are 0.44, 0.35 and 0.29, resp. The corresponding coeffs. for V, VI, VII and VIII are 1.99, 1.7, 0.84 and 0.90. Studying the narcotic action of these ureides shows that

the straight-chain Br-substituted valeric acids have no narcotic action, but the branched-chain ureides show a marked activity paralleling their partition coeffs. The ureides showed decreasing narcotic activity in the order VI, VII and VIII. D. H. POWERS

Saccharose B. AMÉ PICTET AND HANS VOGEL. Univ. of Geneva. *Helv. Chim. Acta* 11, 901-5(1928).—It has been claimed that saccharose (I) recrystd. from EtOH m. 179-80°, while from MeOH it m. 169-70°. The d_{20}^{20} of I from these 2 solns. has recently been found to be 1.5840 and 1.5737, resp. The higher-melting or A form is the common form, and the lower-melting the B form. No other solvents could be found which would convert A into B, but 10% MeOH in EtOH will bring it about. Chem. analysis shows no difference between A and B and on long standing B is quite stable if dry. The octaacetates of the 2 forms have identical m. ps. and all attempts to observe any evidence of a chem. difference give neg. results. Saccharose C and D. *Ibid* 905-9.—5 g. of β -glucose tetraacetate and 5 g. of fructose tetraacetate in CHCl_3 are mixed with P_2O_5 for 14 hrs. The resulting sirup is neutralized, extd. with H_2O and recrystd. from alc. to give 15% of the octaacetate of saccharose C (II), m. 113-4°, $[\alpha]_D^{21} -60.8^\circ$ in CHCl_3 . II gives 74% saccharose C (III), m. 104°, $[\alpha]_D^{22} -24.6^\circ$. III is hydrolyzed only after boiling 1 hr. with 10% HCl to give the invert sugar soln. $[\alpha]_D^{21} -20.4^\circ$. The probable formula for III is $\text{CH}_2(\text{OH})$ -

$$\begin{array}{c} \text{O} \qquad \qquad \qquad \text{O} \\ \text{CH}.\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CH} - \text{O} - \text{C}(\text{CH}_2\text{OH}).\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CH}_2 \\ \text{Octaacetylsaccharose with HCl at room temp. for 3 hrs. gives a sirup which probably is} \\ \text{a mixt. of tetraacetylglucose and -fructose but which could not be sepd. Recondensing} \\ \text{this mixt. by heating for 15 hrs. with } \text{P}_2\text{O}_5 \text{ in } \text{CHCl}_3 \text{ gives what is believed to be the} \\ \text{octaacetate of saccharose D, m. } 125^\circ, [\alpha]_D^{21} 20.3 \text{ in } \text{CHCl}_3. \text{ Sapon. gives saccharose D,} \\ \text{m. } 127^\circ, [\alpha]_D^{21} 19.0. \text{ It is suggested that this disaccharide has the structure: } \text{CH}_2(\text{OH})- \end{array}$$

$$\begin{array}{c} \text{O} \qquad \qquad \qquad \text{O} \\ \text{CH}.\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CH} - \text{O} - \text{C}(\text{CH}_2\text{OH}).\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CHCH}_2\text{OH}. \end{array}$$

Analogies in the catalytic action of enzymes and definite organic substances. WOLFGANG LANGENBECK. *Z. angew. Chem.* 41, 740-5(1928).—While the catalytic effects similar to those of enzymes are well investigated in inorg. chemistry, studies on this subject are scarce in org. chemistry. A summary on the present knowledge of org. catalysts acting similarly to enzymes is given in this article. These org. compds. have a much weaker effect than have enzymes; therefore a relation between the action of the former and the latter is perhaps possible. In esterification, apart from the H^+ ions, weak, undissociated, org. acids have a catalytic effect. In amide formation, the reaction velocity is increased by addn. of org. catalysts. Similarly, in the hydrolysis of the carbohydrates, cyanohydrin and acyloin formation, decarboxylation, and dehydrogenation, the reaction is often hastened. Some hemoglobin derivs. have a peroxidative or catalytic action. Some org. catalysts even possess "stereochem. specificity," i. e., the property of attacking the 2 antipodes of an asym. substance with different velocities.

G. SCHWOCH

Chemistry of starch. XXI. The constitution of glycogen. HANS PRINGSHEIM AND GERTI WILL. Chem. Inst., Univ. Berlin. *Ber.* 61B, 2011-7(1928).—No successful degradation of starch to the building constituents has as yet been accomplished. Heating the plant or the animal carbohydrate in $\text{C}_2\text{H}_5(\text{OH})_2$ yields a trihexose, which amylase changes to maltose. The glycogen used was prepd. from edible mussel, purified by many washings in water and pptd. with alc. $[\alpha]_D^{20} 194^\circ$ (H_2O). The degradation product was acetylated completely by heating for 65 hrs., at 65° one part glycogen, 4 cc. Ac_2O and 6 cc. $\text{C}_6\text{H}_5\text{N}$; $[\alpha]_D^{20} 177.9-175.5^\circ$ (CHCl_3). The mol. wt. in AcOH corresponded to a triacetate hexosan in 0.3% concn.; a higher concn. resulted in assocn. To secure the necessary soln. in CHCl_3 , the glycogen acetate was refluxed 20 min. in boiling C_{10}H_8 . The degradation of glycogen acetate with PhSO_3H was accomplished by dissolving in a 4% soln. of CHCl_3 , cong. to 0.2 of original vol. over P_2O_5 under 14 mm. at 78° and then adding PhSO_3H . Two solns. were refluxed (A) 24 hrs., (B) 72 hrs., the PhSO_3H removed by shaking with NaHCO_3 , the CHCl_3 soln. purified with animal charcoal, concd. to a small vol. and pptd. with Et_2O . (A) 0.1006 g. neutralized by 8.02 cc. 0.1N NaOH yielded 34.3% Ac ; (B) 0.0762 g. neutralized by 4.40 cc. 0.1N NaOH yielded 24.8% Ac . The sapon. of the glycosan was effected with alc. KOH or with $\text{Ba}(\text{OH})_2$; the pptn. by alc. The product was ash-free, sol. in H_2O without opalescence, gave the characteristic brown color with I_2 in KI . The f.-p. method gave the mol. wt. of 3 samples as 473, 476, 452, Mol. wt. detns. by the b.-p. method varied. The hydrolysis

of glycogen and glycogen at 37° was effected (1) with pancreas-amylase alone; (2) pancreas and yeast alone; (3) dil. soln. of pancreas-amylase. Approx. the same yield of maltose was obtained for the same period of time from each carbohydrate, but hydrolysis was most rapid in (3).

GEO. W. MUHLEMAN

The constitution of inulin. HANS PRINGSHEIM AND JOSEPH REILLY. *Chem. Inst. Univ. Berlin. Ber.* 61B, 2018-9(1928).—Recently H. Pringsheim and I. Fellner (*Ann.* 462, 231) prepared inulin acetate from tetraulin acetate, which, saponified, yields a disaccharide anhydride. Another more rapid degradation method (preceding abstract) involves the use of CHCl_3 and PhSO_3H (0.2%). A mol. wt. of 400 was obtained for the disintegration product after 5 hrs. boiling; after 7 hrs. the f. p. mol. wt. detn. gave $(\text{C}_6\text{H}_{10}\text{O}_5)_2$ as the formula. The inulin used was first prepd. by Karrer and is now manufd. by Siegfried, a Swiss firm. Before acetylating the sample was dissolved 3 times in water and pptd. with EtOH ; $[\alpha]_D^{20}$ —33.9°. Two samples by the f.-p. method gave mol. wts. of 1056 and 1088. The acetate after purifying with MeOH gave $[\alpha]_D^{20}$ —41.6°. To sapon. the acetate 5 g. was dissolved in 125 cc. dry CHCl_3 and 0.25 g. dehydrated PhSO_3H added and refluxed 7 hrs. The PhSO_3H was washed out with dil. NaHCO_3 and the CHCl_3 removed by steam distn. Before detg. $[\alpha]$ and the mol. wt. the samples were dried *in vacuo* over P_2O_5 at 78°. Three analyses and 3 mol. wt. detns. averaged (1) C 39.64%, H 6.55%; (2) 348. The computed formula is $\text{C}_6\text{H}_{10}\text{O}_5 \cdot \text{H}_2\text{O} = 39.99\% \text{ C}, 6.71\% \text{ H}$. The optical rotation = —32.1°. G. W. M.

Synthesis of raffinose. HANS VOGEL AND AMÉ PICTET. The Univ. of Geneva. *Helv. Chim. Acta* 11, 898-900(1928).—Raffinose (I) may be considered as a galactosyl-saccharose or a fructosylmelibiose. 7 g. of saccharose (II) and 3.5 g. of galactose (III) are heated at 160-5° under 13-15 mm. for 1.25 hrs. The resulting sirup is extd. with MeOH several times. Slow evapn. of the ext. gives a white solid, which on crystn. from H_2O gives 1% of I. I is identified by m. p., hydrate formation, decompn. p., soly., osazones formed after hydrolysis with 10% HOAc , action with NaOAc , and rotation. It seems probable that III first loses H_2O to form galactosan, which in turn reacts with II to form I.

D. H. POWERS

Some new sugars of the trehalose type. HANS VOGEL AND HALINA DEBOWSKA-KURNICKA. The Univ. of Geneva. *Helv. Chim. Acta* 11, 910-15(1918).—The authors study the action of ZnCl_2 on solns. of monoses to give disaccharides. β -Tetracetylglucose in PhMe is boiled with ZnCl_2 for 2.5 hrs. to reach equil. between the α - and β -forms; P_2O_5 is then added and the boiling continued 6 hrs. There is obtained 15% yield of an octaacetate of a disaccharide which is an α, β -trehalose deriv., m. 68-70°. Sapon. converts it to the corresponding sugar, m. 85°, decompn. 97°, which reduces neither Fehling soln. nor neutral KMnO_4 and is believed to have the structure, $\text{CH}_2(\text{OH})$ -

$\text{CH}(\text{OH})\text{CH}(\text{OH})\text{CH}(\text{OH})\text{CHOCH}(\text{OH})\text{CH}(\text{OH})\text{CH}(\text{OH})\text{CH}(\text{OH})\text{CH}_2\text{OH}$. β -Tetracetylglucose in CHCl_3 , boiled with ZnCl_2 and P_2O_5 gives 18% of a non-reducing sugar, m. 82-3°. Sapon. gives a galactobiose, m. 122°. The rotation of this compd. indicates it may be the α, β -form. Heptaacetylmaltose in CHCl_3 with ZnCl_2 and P_2O_5 for 18 hrs. gives a tetradecaacetylmaltotetrose, m. 105°. Sapon. gives a maltotetrose, m. 120-2°. It does not reduce Fehling soln. and does not form an osazone. It is easily hydrolyzed to glucose.

D. H. POWERS

A benzene model on the basis of the electron theory, and the substitution regularities. M. ULMANN. *Z. angew. Chem.* 41, 674-80(1928).—Speculations based on the electron theory induced U. to advance a space model of PhH , which allows of explaining satisfactorily the aromatic character of PhH and its derivs., and the phenomena observed in the chemistry of PhH , as well as the vanishing of the aromatic character on hydrogenation, the regularities of substitution and the displacement reactions. A similar model was devised for pyridine.

G. SCHWACH

Production of benzene and of toluene from technical xylene and from solvent naphtha. G. L. YUKHNOVSKIY. *Ukrainskii Khim. Zhurnal* 3, No. 2, Pt. techn., 65-87(1928).—A study has been made of the yields of benzene and of toluene on passing the raw materials mixed with H through heated tubes filled with various materials. At 750-75° the best results on passing xylene were obtained with Fe tubes covered with a layer of sulfide and filled with pieces of FeS or with NiS . Cu tubes filled with Cu filings gave similar results, about 60% of the theoretical yield being obtained in each case. CoS was found to be less efficient. Fe and particularly Ni promote decompn. of hydrocarbons with deposition of C. Al and Mg oxides are reduced by the reactants under the conditions of the expts. and the yields of liquid hydrocarbons are very small initially. Later, when reduced, these contact substances give very high yields, 60-75%

of the theoretical. With solvent naphtha b. 145–70°, Al_2O_3 and FeS gave, resp., 75 and 61% yields of fractions boiling below 135°. The reaction with xylene, by using a reduced Al_2O_3 contact mass, begins at 670°, the yield of the desired hydrocarbons increasing up to 770°. At still higher temp. the yield begins to fall off. The ratio $\text{C}_6\text{H}_6:\text{PhMe}$ increases with the temp. over the whole temp. range investigated. At 730° practically no benzene is formed, at 815° its yield is about 43% of the total yield. The effect of temp. on the yields is somewhat similar when FeS or Cu is used as contact. With Ni the favorable temps. are lower. Attempts to prep. benzene and toluene by using, instead of H , either illuminating gas contg. 3% H , or Ni , gave tarry products with only small yields, not exceeding 30%, of lower-boiling hydrocarbons. G. B. KISTIAKOWSKY

Nitro derivatives of dibenzylaniline. RANCHHODJI DAJBHAI DESAI. College of Baroda. *J. Indian Chem. Soc.* 5, 425–31 (1928).—Ten g. of $\text{PhN}(\text{CH}_2\text{Ph})_2$ and 3 cc. HNO_3 (d. 1.48) in 125 cc. AcOH at 5–10° gave 9.5 g. *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{N}(\text{CH}_2\text{Ph})_2$ (I), and 1 g. *o*-nitrodibenzylaniline, which is an oil. The isomers were sepd. by EtOH , in which the *o*-compd., but not the *p*-compd., was sol. I was also obtained from *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{NH}_2$ and PhCH_2Cl . From I with Zn and HCl in alc., was prepd. the Zn salt of *p*-aminodibenzylaniline, white, m. 200–2°, which by decompn. with alkali gave the free base (II); *Ac deriv.* (III), m. 137–8°; *Bz deriv.*, m. 166°. From II (1.5 g.) and BzH (1.5 g.) at 0° is formed, benzylidene-*p*-dibenzylaminoaniline (IV), yellow, m. 166–7°, and not $\text{PhCH}(\text{OH})\text{NHC}_6\text{H}_4\text{N}(\text{CH}_2\text{Ph})_2$, m. 130°, which Matzudaira (*Ber.* 20, 1611) claims to have obtained by the same reaction. IV gives III, when heated with Ac_2O ; *HCl salt* of IV; *dibromide*, m. 220–5° (decompn.). *p*-Nitrodibenzylaniline (V) (from 14 g. *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{NH}_2$, 13 g. PhCH_2Cl , 9 g. anhyd. AcONa and 0.2 g. I at 125–30° for 8 hrs.), golden yellow, m. 147°. With Zn and HCl in alc., V gives an oil (VI). *Ac deriv.* of VI, m. 141–2°; *Bz deriv.*, m. 182–3°. Benzylidene-*p*-benzylaminoaniline, from 2 g. VI and 2 g. BzH at 0°, pale yellow, m. 92–3°; *HCl salt*, m. 170–2°; *dibromide*, yellow, m. 210° (decompn.). *o*-Nitrodibenzylaniline (20 g. from 13.8 g. *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{NH}_2$, 40 g. PhCH_2Cl , 17 g. anhyd. AcONa and 0.2 g. I heated on a sand bath for 15 hrs.), yellow, m. 32–3°; reduced to an oil by Zn and HCl ; *Ac deriv.*, m. 121–2°; *Bz deriv.*, m. 155–6°. *m*-Nitrodibenzylaniline (VII) (25 g. from 14 g. *m*- $\text{O}_2\text{NC}_6\text{H}_4\text{NH}_2$, 26 g. PhCH_2Cl , 18 g. anhyd. AcONa and 0.2 g. I heated to 125–30° for 5 hrs.), golden yellow, m. 73–4°; *HCl salt*, m. 140–2°. *m*-Aminodibenzylaniline (from VII with Zn and HCl) is an oil, oxidized by air; *Ac deriv.*, m. 143–4°; *Bz deriv.*, m. 171–2°. Benzylidene-*m*-dibenzylaminoaniline (from 1.5 g. VII and 1.5 g. BzH at 0°), yellow, m. 156–8°; *HCl salt*, m. 195° (decompn.). *dibromide*, yellow, m. 196–8° (decompn.). Ten g. $\text{PhN}(\text{CH}_2\text{Ph})_2$ with 10 g. HNO_3 (d. 1.48) in AcOH at 15–20° gave 2,4-(O_2N) $_2\text{C}_6\text{H}_3\text{N}(\text{CH}_2\text{Ph})_2$ (VIII), m. 103–4°, and not 106° (Pinnow and Wiskow, *Ber.* 32, 913). Besides VIII, 0.5 g. of 2,6-dinitrophenyldibenzylamine (IX), m. 107°, orange-yellow, was obtained. VIII (1 g.) refluxed with 5 cc. Ac_2O and 1 cc. HCl for 2 hrs. is decompd. to 2,4-(O_2N) $_2\text{C}_6\text{H}_3\text{NHC}_6\text{H}_4\text{Ph}$ and PhCH_2Cl . When the same mixt. is heated at 145–50° for 8 hrs., a heavy oil is formed, which by acetylating gave pale white needles of 2,4-(O_2N) $_2\text{C}_6\text{H}_3\text{NHAc}$. Refluxing 0.3 g. of IX with 1 cc. HCl and 3 cc. Ac_2O for 2 hrs. gave 2,6-(O_2N) $_2\text{C}_6\text{H}_3\text{NH}_2$. G. S.

Action of nitrosodimethylaniline on unsaturated compounds. A. QUILICO. Reale Politecnico, Milano. *Gazz. chim. ital.* 58, 317–25 (1928).—Researches of Angeli, Alessandri and Pegna (*C. A.* 4, 2457), of Alessandri (*C. A.* 9, 2240; 16, 558), of Bruni and Geiger (*C. A.* 21, 4092) and of Meyer, Irschick and Schlosser (*C. A.* 8, 2878) which show that various types of unsatd. compds. react through their double bonds with NO compds. induced Q . to expt. with $\text{ONC}_6\text{H}_4\text{NMe}_2$ (I). When I and safrole (equimol. parts) are maintained at ordinary temp., there is no reaction, but on heating gradually to 120–30° a violent reaction begins, the temp. increasing spontaneously to 200°. On a water bath the reaction can be controlled. I (7.5 g.) added slowly, with warming, to safrole (8.1 g.), heated 5–6 hrs. on a water bath, let stand several days in darkness, EtOH (a few cc.) added, filtered, the residue washed with a little cold EtOH , then treated with boiling EtOH and filtered hot, leaves azodimethylaniline and a filtrate from which on cooling sep. brown-yellow crystals, which after recrystn. from xylene and then from EtOH , yield a golden yellow compd. $\text{C}_{15}\text{H}_{15}\text{O}_2\text{N}_2$ (II), m. 159–60°. It is stable in air and direct sunlight, is insol. in alkalis, gives intense red solns. in dil. acids (including AcOH) which reppt. when alkalis are added, and with alk. KMnO_4 forms piperonylic acid. Dissolved (2 g.) in 25% H_2SO_4 (100 cc.), II gives an intense red soln. which, filtered rapidly to remove floating oily drops and the latter (which eventually crystallize) recrystd. from EtOH yield $\text{CH}_2\text{O}_2\text{C}_6\text{H}_4\text{CH}=\text{CHCHO}$ (III) (cf. *Ber.* 27, 2958 (1894)); *C. A.* 4, 2457). The filtrate contains the sulfate of II, $\text{C}_{15}\text{H}_{15}\text{O}_2\text{N}_2\cdot 2\text{H}_2\text{SO}_4$ (IV), red, m. 195–8°, from which by the action of alkalis II is liberated. Excess 10% NaOH added to aq. IV, then a little BzCl added, first ppts. II, but with agitation this changes its character,

and filtered, the residue washed with EtOH, dissolved in AcMe, pptd. with water and recrystd. from xylene and then EtOH, yields the *B₂ deriv.* of *p*-H₂NC₆H₄NMe₂, C₁₀H₁₆ON₂, (V), m. 216–7°. This can also be prepd. from *p*-H₂NC₆H₄NMe₂ and BzCl, with recrystn. from EtOH and xylene, in which case it m. 217–8°. HONH₃Cl (0.35 g.) and Na₂CO₃ (0.30 g.) in a little water added to II (1 g.) in EtOH (50 cc.), refluxed 1 hr., all EtOH evapd., pptd. with water and recrystd. from C₆H₆, yields the oxime of II, CH₂O₂:C₆H₅CH:CHCH:NOH, m. 155°, which is the compd. called the γ -form by Angeli, Alessandri and Pegna (*loc. cit.*). In AcOH medium, there is obtained besides a large yield of the γ -form, a small proportion of the α -isomer (cf. A., A. and P.). Thus HONH₃Cl (1.5 g.) and Na₂CO₃ (1 g.) in a little water added to II (2.5 g.) in glacial AcOH (50 cc.), heated on the water bath, dild. with water and filtered, yield 1.7 g. of crude product. The mother liquor heated to remove AcOH, made alk. with Na₂CO₃, steam distd., the residue filtered, a little NaOH and BzCl added, the ppt. boiled with EtOH and recrystd. from boiling xylene, yields V. When the mixt. of oximes is treated with boiling EtOH, the γ -form dissolves, leaving the α -form. *p*-H₂NC₆H₄NMe₂ warmed with III (the calcd. quantity) in a little EtOH, filtered and the residue recrystd. from EtOH and xylene, yields II. The reactions indicate that II is a Schiff base of the compn.: CH₂O₂:C₆H₅CH:CHCH:NC₆H₄NMe₂. The possible mechanism of the reactions is discussed.

C. C. DAVIS

Organic sulfur compounds. X. Remarks on the action of air on thiobenzophenone. A. SCHÖNBERG, O. SCHÜTZ AND S. NICKEL. *Techn. Hochschule Charlottenburg Ber* 61B, 2175 7(1928), cf. C. A. 22, 4510.—Since the compd. C₂₆H₂₆S₃ (I) obtained along with Ph₂CO by the action of air on Ph₂CS and briefly described, with reservations as to its possible structure, in the earlier paper, has been obtained independently by Standinger and Freudenberger (C. A. 23, 130), the authors hasten to publish the results they have thus far obtained in order not to keep other workers out of the field. On soln. and fusion it decomps. into Ph₂CS and S and is therefore a trisulfide, either 3,3,5,5-tetraphenyldimethylene 1,2,4-trisulfide, Ph₂C:S:S:CPh₂:S (I) or

1,4,5,5-tetraphenyldimethylene 1,2,3-trisulfide, Ph₂C:S:S:S:CPh₂ Structure I is given the

preference. I is a deriv. of the hitherto unknown benzohydril thioether, (Ph₂CH)₂S (II), which can readily be obtained from Ph₂CHBr and Ph₂CHSH and, like I, decomps. into Ph₂CS on heating. I, from Ph₂CS allowed to stand 4 weeks in the air, boiled 1 min. in benzene and filtered hot (max. yield, 15%), colorless crystals, forms in cold C₆H₆, CHCl₃, (CH₂Br)₂ or CS₂ almost colorless solns. which, however, soon become light blue, dissolves in concd. H₂SO₄ with yellow color changing to red-brown, m. about 124° (decompn.), mol. wt. in freezing C₆H₆ 405. II (with J. PETER) (4 g. from 5 g. Ph₂CHSH and 7 g. Ph₂CHBr refluxed in C₆H₆ in CO₂), m. 66.5°, forms a blue melt (Ph₂CS) when heated 30 sec. at 275°, dissolves in concd. H₂SO₄ with somewhat greenish yellow color.

C. A. R.

***o*-Aminophenylhydrazine and some interesting heterocyclic compounds derived from it. IV. Lengthened *o*-derivatives of benzene and their ring-closure.** PRAPHULLA CHANDRA GUHA AND TEJENDRA NATH GHOSH. *Univ. Dacca. J. Indian Chem. Soc.* 5, 439 51(1928). In continuation of their studies (cf. C. A. 22, 2506), G. and G. investigated the interaction of aminophenylsemicarbazides with various compds. In some of the substances prepd. by these reactions, a ring closure could be attained. A ring closure was also found to occur on reduction of some derivs. of *o*-O₂NC₆H₄NHNH₂ (I). *o*-Nitrophenyl 4-phenylsemicarbazide (II) (from 3.5 g. OC:NPh and 5 g. HCl salt of I in H₂O), yellow, m. 202°. 5 g. II was heated with 15 g. Sn and 100 cc. concd. HCl on the water bath for several hrs. From the resulting colorless soln. after cooling and dilg. with 150 cc. H₂O, 0.7 g. of 1-phenyl 2,3-benzo-6-keto 1,4,5-triazine (III) seps. out, m. 170–1°, sol. in dil. alkali. From the mother liquor was isolated 1-*o*-aminophenyl-4-phenylsemicarbazide-HCl (IV), m. 250–1° (decompn.), which gives a red azo dye on diazotization and coupling with β -naphthol. The free base, brownish, m. 145°. 1 g. IV refluxed with 3 cc. Ac₂O on the sand bath for 20 min., gives a compd., m. 170–1°, identical with III. 1-Phenylcarbamido-2-phenylsemicarbazidobenzene (from 0.5 g. OC:NPh and 1 g. IV), m. above 290°. 1-Carbamido-2-phenylsemicarbazidobenzene (V) (from 2 g. IV and 0.6 g. KOCN in H₂O), did not m. 290°, sol. in alkali. By heating 2 g. of V with 100 cc. concd. HCl for 1 hr., 1.2 g. of 2,3-benzo-6-phenylamino-8-keto-1,4,5,7-octatetrazine, m. 145–6°, was obtained. 1-Phenylthiocarbamido-2-phenylsemicarbazidobenzene (from 0.5 g. SC:NPh and 1 g. IV by heating on the water bath for 2–3 hrs.), brownish white, m. above 290°. 1 g. HCl salt of IV and 0.5 g. *o*-O₂NC₆H₄CHO gave 1-*o*-nitrobenzalanilido-2-phenylsemicarbazidobenzene, m. 245–6°. With FeCl₃

acting on IV, there results *3,4-benzo-7-phenylamino-1,2,5,6-oxheptatriazine-HCl*, reddish brown, does not m. 290° . Reaction of 2 g. IV with 0.4 g. $(\text{NH}_4)_2\text{H}_2\text{O}$ yielded *1-N-phenyl-3,4-benzo-7-hydroxy-1,4,5,6-heptatetrazine*, m. $90-1^{\circ}$, sol. in dil. alkali. By dropping 1 g. KOCN in H_2O into a concd. soln. of 2 g. HCl salt of I, *o-nitrophenylsemicarbazide* (VI), yellow, m. 225° (decompn.), was prepd. The HCl salt of *2,3-benzo-5-imino-1,4,6-triazine* (VII), brownish white, m. $248-9^{\circ}$ (decompn.), was obtained by refluxing 5 g. VI with 10 g. Sn in 60 cc. concd. HCl for 1 hr.; the free base m. 85° , whose brownish white *Ac deriv.* m. $182-3^{\circ}$. 5 g. HCl salt of I and 3 g. KSCN in H_2O yielded 5 g. of *1-o-nitrophenylthiosemicarbazide* (VIII), light yellow, m. 200° (decompn.). Reduction of VIII, carried out similarly as described for VI, resulted in formation of VII. *o-Chlorobenzaldehyde-o-nitrophenylhydrazone* (IX) (from 2 g. I and 2 g. *o*- $\text{ClC}_6\text{H}_4\text{CHO}$ by refluxing in alc. for 20 min.), orange-yellow, m. 171° . Reduction of IX with Sn and HCl gave rise to the formation of *2,3,7,8-dibenzo-1,4,5-octatriazine-HCl*, m. 285° ; the free base m. $217-8^{\circ}$. Glyoxal *o-nitrophenylosazone* (X) (from 3 g. HCl salt of I and 2.5 g. glyoxal- NaHSO_3 under reflux), red, m. $279-80^{\circ}$ (decompn.). *Bisbenzimidazole-HCl* was obtained by reduction of X with Sn and HCl, m. 253° (decompn.); its free base, brown, m. above 300° ; *di-Ac deriv.*, m. $183-4^{\circ}$. 10 g. CS_2 and 5.5 g. KOH were dissolved in a little H_2O and dropped into 10 g. I in 80 cc. EtOH at 0° . The resulting blue soln. is treated with 13 g. MeI. Pptn. of red *Me o-nitrophenyldithiocarbazinate* (XI) occurs, m. $113-4^{\circ}$ after recrystn. Reduction of XI results in formation of *2,3-benzo-6-methylthiol-1,4,5-triazine-HCl*, whose free base m. $199-200^{\circ}$. *Di-o-nitrophenylcarbohydrazide* (XII) (by refluxing 5 g. I in PhH with 7.5 g. of 20% OCCl_2 soln. in MePh), yellow, m. $260-1^{\circ}$. *2,3,9,10-Dibenzo-6-keto-1,4,5,7,8-decapentazine-HCl*, brownish white, m. $251-2^{\circ}$, was prepd. in the usual manner by reduction of XII. The free base was too unstable to be isolated. *Et o-nitrophenylcarbazinate* (from I and $\text{ClCO}_2\text{C}_2\text{H}_5$), brownish white, m. 185° .

G. SCHWOCH

Addition compounds between phenols and ammonia. III. The phenolammonia-system. E. BRINER AND O. AGATHON. Univ. of Geneva. *Helv. Chim. Acta* 11, 922-5(1928); cf. C. A. 22, 63.—It has been previously shown that the m. p. curve shows a flattening indicating the formation of a compd. $\text{PhOH}\cdot\text{NH}_3$. The vapor-pressure method is applied to this system and the results are plotted. At the 1st introduction of NH_3 to the PhOH, small drops of a liquid appear which increase in size until the entire mass is liquid. This liquid is a mixt. of the $\text{PhOH}\cdot\text{NH}_3$ compd. and PhOH. IV. Ammoniations of naphthols, diphenols, hydroxybenzoic acids, hydroxyanthraquinones and *o*-nitrophenols; heats of ammoniation. E. BRINER AND A. MORF. *Ibid* 926-44.—Working at 0° it is established that α -naphthol immediately takes up 1 mol. of NH_3 . Its disson. pressure is 16 mm. at 0° and 56 mm. at 20° . β -Naphthol (I), at 20° rapidly takes up NH_3 without liquefying. The compd. first formed is β -naphthol-0.5 NH_3 (II). The compd. β -naphthol- NH_3 (III), forms much more slowly. I in liquid NH_3 at -50° ppts. a solid which is probably II, but on evapn. of the NH_3 , only III is obtained. The heats of ammoniation of II and III are detd. as 5 and 9 cal, resp. *o*- $\text{C}_6\text{H}_4(\text{OH})_2$ at 20° shows clearly the formation of *o*- $\text{C}_6\text{H}_4(\text{OH})_2\cdot\text{NH}_3$ (IV), but only at 0° is there evidence of the compd. *o*- $\text{C}_6\text{H}_4(\text{OH})_2\cdot 2\text{NH}_3$ (V). The heats of ammoniation for IV and V are detd. as 13 and 18 cal. No evidence of any change of cryst. structure is noted with the formation of these compds. *m*- $\text{C}_6\text{H}_4(\text{OH})_2$ also forms the mono- and diammoniates; *p*- $\text{C}_6\text{H}_4(\text{OH})_2$ gives the mono- and diammoniates and this is the only case where they are both cryst. compds. *o*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$ rapidly forms a monoammoniate and there is also a flattening of the curve indicating a compd. with 2NH_3 . *m*- and *p*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$ both react rapidly to form the monoammoniate and very slowly to form the diammoniate. α -Hydroxyanthraquinone at 78° or 110° slowly forms a deep red monoammoniate. β -Hydroxyanthraquinone takes up the first 0.5 mol. of NH_3 very rapidly and the second 0.5 mol. slowly, but there is no evidence for a compd. of lower NH_3 content than the light red β - $\text{C}_{14}\text{H}_9\text{O}_2\text{OH}\cdot\text{NH}_3$. 2,3-Dihydroxyanthraquinone reacts rapidly with one NH_3 ; the 1,2-deriv. reacts slowly and the 1,4-deriv. very slowly. *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{OH}$ forms a mono- and a triammoniate with heats of ammoniation of 17.6 and 33.6 cal.

D. H. POWERS

The cleavage of eugenol ethylene ether on reduction. ALEXANDER ST. PFAU. Givaudan et Cie, Genf-Vernier. *Helv. Chim. Acta* 11, 877-81(1928).—Thoms and Heynen (C. A. 22, 3153) have stated that when eugenol ethylene ether is reduced with EtOH and Na one of the products is the β -hydroxyethyl ether of dihydroeugenol (I), b_p 144° , orange-like odor. Since neither the b. p. nor the odor of I corresponded to its constitution, P. repeated the expt. His results verified for the most part those of T. and H. However, the odor of the reaction product was found to be due exclusively to *m*- $\text{PrC}_6\text{H}_4\text{OMe}$, and I when pure m. 50.5° , b_p 170° .

LOUISE KELLEY

Vinylene homologs of *p*-dimethylaminobenzaldehyde. W. KÖNIG, W. SCHRAMMEK AND G. RÖSCH, in part with H. ARNOLD. *Sächs. Techn. Hochschule Dresden. Ber.* 61B, 2074-80(1928).—In order to synthesize various "vinylene-homologous" series of colored substances to study the influence of successive lengthening of the conjugated C chain on the light absorption, it was especially desirable to obtain the compds. of the general type $p\text{-Me}_2\text{NC}_6\text{H}_4(\text{CH}:\text{CH})_n\text{CHO}$ (I) ($n = 0, 1$, etc.). The 2nd member (II) ($n = 1$) had been prep'd. by Feder and by Möhlau and Adam from $\text{Me}_2\text{NC}_6\text{H}_4\text{CHO}$ (III) and paraldehyde with concd. H_2SO_4 . M. and A. describe it as yellow leaflets, m. 133° and state it can be obtained in better yield from AcH than from paraldehyde. On repeating their work systematically the present authors were never able to obtain the high yield (about 70%) reported by M. and A. and they found, moreover, that pure II is obtained much more satisfactorily in about 40% yield from paraldehyde provided the reaction is not allowed to proceed beyond a certain time limit; otherwise there are formed together with much AcH resins, various higher vinylene homologs of II, resulting from continued aldol condensation and subsequent elimination of H_2O . F.'s and M. and A.'s product was probably contaminated with these substances or with unchanged III, for pure II is orange-yellow and m. 141° . The presence of higher homologs is easily detected by the color reactions in alc. with aromatic amines and mineral acids; the "azomethine dye salts" so obtained from II are red, those from the higher homologs violet to green-blue. By fractional alkali pptn. of the product of a condensation which had been allowed to proceed a long time there was obtained 6% of the 4th member ($n = 3$) of the series, viz. *1-p-dimethylaminophenyl-1,3,5-heptatrien-7-al* (IV). Once, in attempting to purify IV by soln. in about 60% H_2SO_4 there remained a very small quantity of a difficultly sol. yellow sulfate which was hydrolyzed by H_2O with brown color and could then be recrystd. from AcOEt. The substance (V) could never be obtained again, but its crimson onium-halochromism in concd. H_2SO_4 , its compn. and its absorption curve indicate that it is the pentavinylene compd. *1-p-dimethylaminophenyl-1,3,5,7,9-undecapentaen-11-al* (I, $n = 5$). The absorption curves of II, III, IV and V are all very similar in form; each additional $\text{CH}:\text{CH}$ shifts the absorption max. further towards the longer wave lengths (max. in EtOH for the 4 compds., 340, 390, 440, 470μ , resp.). The missing members ($n = 2$ and 4) cannot be obtained directly by the paraldehyde- H_2SO_4 process (even with $\text{MeCH}:\text{CHCHO}$ instead of paraldehyde or II instead of III), but from II and AcCO_2H with H_2SO_4 at 40° was obtained, along with a blue acid (to be described later) as chief product, a small quantity of an orange-yellow substance (VII), which from its red-yellow halochromism in concd. H_2SO_4 , the violet color of its PhNHMe condensation product and its absorption in alc. (max. at 420μ) is undoubtedly *1-p-dimethylaminophenyl-1,3-pentadien-5-al*. *Phenylhydrazone* of II, light yellow phototropic needles, m. 169° ; *oxime*, yellow, m. 151° . *Streptotriavinylene-p-dimethylaminobenzaldehyde* (IV), red needles from benzine, m. 184° , Cu-red leaflets from AcOEt, m. 176° ; *phenylhydrazone*, m. 217° . V, deep brown needles with Cu luster, m. 209° , forms a pure blue condensation product with HClO_4 and PhNHMe . VII m. around 155° . C. A. R.

The Nierenstein reaction. W. BRADLEY AND R. ROBINSON. *Nature* 122, No. 3065, 130-1(1928).—A correspondence declaring the inability of corroborating the results of the Nierenstein reaction. The reaction in question is: (A) $\text{BzCl} + \text{CH}_2\text{N}_2 = \text{BzCH}_2\text{Cl} + \text{N}_2$. B. and R. believe it takes place as: (B) $\text{BzCl} + \text{CH}_2\text{N}_2 = \text{BzCHN}_2 + \text{HCl}$; (C) $\text{HCl} + \text{CH}_2\text{N}_2 = \text{CH}_3\text{Cl} + \text{N}_2$; (D) $\text{BzCHN}_2 + \text{HCl} = \text{BzCH}_2\text{Cl} + \text{N}_2$; (E) $\text{BzCl} + 2\text{CH}_2\text{N}_2 = \text{BzCHN}_2 + \text{CH}_3\text{Cl} + \text{N}_2$. Expts. showed that (C) occurred more rapidly than (D). Equations (B) and (C) represent the reaction when BzCl is added to CH_2N_2 , (E) when the chloride is added slowly to the CH_2N_2 and when 2 or more mols. of CH_2N_2 are added to 1 of BzCl . A diazoketone will be formed when an excess of CH_2N_2 is used. When equal parts of CH_2N_2 are added to BzCl the products are mainly N_2CHBz , a little BzCl and small amounts of ClCH_2Bz . This indicates that (D) is not the primary reaction and that (B) and (C) are more rapid than (D). (B) will be followed eventually by (D). A higher yield of N_2CHBz will occur if the product is worked up after a short time and a high yield of ClCH_2Bz will occur if the reagents are mixed rapidly and the mixt. is kept many hours. JOHN T. WOLF

Isomerism of the chalcones. JOSE PASCUAL-VILA. *Anales soc. españ. fis. quim.* 26, 222(1928).—The phenomena of isomerism of *cis*- $\text{PhCH}:\text{CHCO}_2\text{H}$ is found in various other substances with the chalcone group $\text{CPhC}:\text{C}(\text{O})-$, as can be seen in recent articles by Dufraisse (*C. A.* 21, 575) and others by Weygand (*C. A.* 22, 953). In the α -phenylnitrochalcones Stobbe, however, encountered examples of analogous isomerism. Accidentally P. found one in the true α -phenylchalcone and benzaldehydobenzoin. Bromobenzyldehydobenzoin, $\text{PhCOCBr}(\text{CH}_2\text{Ph})\text{Ph}$, which with AgOAc at ordinary

temp. gives isobenzaldesoxybenzoin in excellent yields (J. Pascual-Vila, *C. A.* **19**, 826), gives when boiled with KOAc in AcOH , dild. with water, extd. by ether, concd., dild. with petroleum ether and recrystd., white needles, m. $78-9^\circ$ and with the same halochromism with H_2SO_4 as isobenzaldesoxybenzoin. The latter substance is yellow. The new isomer was converted then into isobenzaldesoxybenzoin. The m. p. differs perhaps from the true m. p. by $1-2^\circ$ because of the thermometer error; it was not of sufficient interest for a redetn.

E. M. SYMMES

Chemical constituents of the fruit of *Ginkgo biloba*. I. JIPPEI KAWAMURA. Forstversuchsanstalt, Meguro bei Tokyo. *Japan. J. Chem.* **3**, 89 108(1928).—Gingkoic acid, $\text{C}_{24}\text{H}_{48}\text{O}_2$, which Schwarzenbach (*Fortschritte Chem.* **1857**, 529) stated was present in the Et_2O ext. of *Ginkgo biloba* (I), was not obtained from I by K., who believes that S.'s product was probably a mixt. of several substances. The air-dried fruit of I was extd. with Et_2O , and the Et_2O layer shaken with 5-10% Na_2CO_3 . The Et_2O soln. was then shaken with an excess of dil. NaOH, and the mixt. sepd. into an Et_2O layer (II) and an aq. alk. layer (III). II was evapd. to small vol. and cooled, whereupon there sepd. crystals of ginnol (IV), $\text{C}_{27}\text{H}_{46}\text{O}$, m. 82.5° . Ac deriv., m. $43.3.5^\circ$. IV with $\text{K}_2\text{Cr}_2\text{O}_7$ in glacial AcOH gave ginnone, m. $74-5^\circ$. Semicarbazone, m. 45.6° ; oxime, m. $49-50^\circ$. III was acidified with dil. HCl and extd. with Et_2O . After evapn. of the Et_2O , the residue was dissolved in EtOH, treated with $(\text{AcO})_2\text{Pb}$ and neutralized with NaOH. The Pb salt (V) pptd. was filtered off and washed with dil. EtOH and Et_2O . These solns. were shaken with dil. HCl, washed, dried and the Et_2O evapd. A brown sirup remained, from which crystd. bilobol, $\text{C}_{21}\text{H}_{40}\text{O}_2$, m. 36.7° . Reduced with H and Pt black it gave hydrobilobol, m. $89-90^\circ$. Acetylhydrobilobol, $\text{C}_{21}\text{H}_{38}\text{O}_2\text{Ac}$, m. 56° . Dinitrohydrobilobol, $\text{C}_{21}\text{H}_{34}\text{O}_2(\text{NO}_2)_2 \cdot \text{H}_2\text{O}$, reddish yellow, m. 68.71° . V was suspended in Et_2O and shaken with dil. HCl. Evapn. of the Et_2O layer gave a cryst. mass which was sepd. into 2 portions by means of petroleum ether. The less sol. portion was apparently hydrogingkolic (cyclogallipharic) acid (VI). The other portion was gingkolic acid (VII), $\text{C}_{21}\text{H}_{38}\text{O}_3$, m. $42-3^\circ$. VII, heated quickly to 240° in a H atm., gave CO and gingkol (VIII), b. $221-3^\circ$, d_4^{20} 0.9148, n_D^{20} 1.50217. Reduced in abs. EtOH with H and Pt black, VII gave VI, m. $86-8^\circ$. VI in glacial AcOH with concd. HNO_3 at room temp. gave $\text{C}_{21}\text{H}_{33}\text{O}_4\text{NO}_2$, yellow, m. 66.8° , with fuming HNO_3 on the water bath another NO_2 deriv., yellow, m. 55.6° . Me ester, from VI and CH_3N_3 in abs. EtOH, m. $41-2.5^\circ$. VIII reduced with H and Pt black gave hydrogingkol, m. $50.5.1^\circ$ (the mixt. with cyclogallipharol melts at the same temp.). p Nitrobenzoylhydrogingkol, m. $60.1.5^\circ$. VIII with Na and MeI in abs. EtOH gave the Me ether (IX), b. 200.3° , d_4^{20} 0.8996, n_D^{20} 1.49454. IX oxidized with KMnO_4 in Me_2CO gave a di-HO deriv., $\text{C}_{21}\text{H}_{34}(\text{OH})_2\text{OMe}$, m. $98-8.5^\circ$. The juice of the fruit of I contained 73.08% H_2O and 26.92% dry material, chiefly reducing sugar. The P in the juice was present chiefly as phosphate, the N as asparagine.

LOUISE KELLEY

Constituents of derris root. III. Tubaic acid. T. KARIYONE, K. KONDO AND K. MAKABE. *J. Pharm. Soc. Japan* **48**, 674 8(1928).—In paper II (*C. A.* **19**, 1708) it was reported that tubaic acid (I) $\text{C}_{17}\text{H}_{12}\text{O}_6$ is a monohydroxymonocarboxylic acid contg. 1 double bond. In order to det. the exact position of the double bond the ozonide reaction of I was studied. I, MeI and Ag_2O and subsequent sapon. with EtOH-KOH gave tubaic acid methyl ether (II), $\text{C}_{17}\text{H}_{14}\text{O}_6$, m. 78° . II, H_2 and Pd BaSO_4 gave the dihydro deriv. (III), m. 101° , which was also obtained by methylation of hydrotubaic acid. Trinitro deriv. of III, m. 133° . II and O_3 and subsequent decompn. of the ozonide with H_2O gave an aldehyde acid (IV), $\text{C}_{12}\text{H}_{12}\text{O}_6$, m. 98.5° . This reaction shows that I should have a $\text{CH}_2\text{:CH-}$ group attached at the end of a side chain so that the reaction can be expressed by $\text{CH}_2\text{:CHC(H}_2\text{O(OMe)CO}_2\text{H)} \rightarrow \text{OHCC(H}_2\text{O(OMe)CO}_2\text{H)}$. Of 4 O atoms, 2 belong to the CO_2H group while 1 belongs to the OH group. The remaining O atom probably forms an ether linkage. An attempt to obtain a compd. devoid of OH and CO_2H groups in order to study the nature of the remaining O atom was unsuccessful. Boiling of hydrotubaic acid (V) with HBr gave hydrotubanol, m. 121° . Mono-Ac deriv., m. 63° . V and PCl_5 and subsequent decompn. with H_2O gave chlorohydrotubaic acid (VI), m. 201° . Reduction of IV with H_2 and Pd gave desoxyhydrotubaic acid (VII), $\text{C}_{10}\text{H}_{10}\text{OC(O}_2\text{H)}$, m. 192° . Boiling of VI with HI gave chlorohydrotubanol (VIII), b. 111.2° . The mol. refraction (54.34) of VIII indicates the presence of at least 3 double bonds. The above reactions show that I has the structure $\text{C}_5\text{H}_7(\text{---CH:CH}_2)(\text{---OH})(\text{---CO}_2\text{H})(\text{>O})$.

NAO UYEI

Modern tannin chemistry. J. DEKKER. *Gerber* **54**, 113-5, 122-3, 130-2, 150-1, 155-6(1928).—A critical review. D. distinguishes 3 types of tannin, which are derivs. of gallic acid, ellagic acid and catechol, resp. Fischer's pentagalloylglucose and

pentadigalloylglucose have many properties in common with Turkish and Chinese gallotannin, resp., but are not identical with these natural products. Most natural tannins are extremely complex mixts. of related substances. In addn. to glucose other carbohydrates may be present, and other aromatic substances may replace gallic or digallic acid. Ellagic acid plays the role of gallic acid in some tannins, e. g., in myrobalam, and is present in many others, possibly combined with gallic acid in a mixed depside. The catechol tannins, e. g., gambier and acacia, are considered to be polymerization products of catechol. Recent work on the structure of catechol is discussed. Several distinct catechols probably exist. In addn. to true tannins D. distinguishes a group of substances having all the tannin reactions except the property of pptg. gelatin. These substances are derivs. of chlorogenic acid. • H. B. MERRILL.

Formation of heterocyclic compounds. III. Interaction of cyclohexanol-2-carboxylates with phenols. HERMENDRA KUMAR SEN AND UMAPRASANNA BASU. Univ. College Science Technol., Calcutta. *J. Indian Chem. Soc.* 5, 467-76 (1928); cf. *C. A.* 21, 2696.—The reaction between cyclohexanol-2-carboxylates and phenols yields benzo- α -pyrones, though according to the theory of Jacobson and Ghosh (*C. A.* 9, 2222, 2762), γ -pyrones should be expected to form. The evidence that in these reactions α -pyrones are formed, is based on the observation that keto nitriles of the type

—COCCN, when condensing with phenols, give rise to formation of imino compds.,

which yield α -pyrones on hydrolysis (*C. A.* 13, 582, 1473). By hydrolysis of the condensation product prepd. from 2-cyanocyclohexanone (I) and *m*-(HO)₂C₆H₄ (II), a compd. identical with that prepd. by condensation of II with Et cyclohexanone-2-carboxylate (III) was obtained. The behavior of the condensation products toward alkali, however, did not support the α -formula. No benzo- γ -pyrones could be prepd. in these expts., though even P₂O₅ was used as a condensing agent in some expts. 3,4-Tetrahydrobenzo-7-hydroxycoumarin (IV) (from a mixt. of II, III, and concd. H₂SO₄ at 0°, or with better yield, at room temp.), m. 202° (Dieckmann, *Ann.* 317, 27, reported m. p. 203-4°), sol. in alkali and alkali carbonates, gives no color with FeCl₃, sol. in concd. H₂SO₄ with violet fluorescence; *Ac deriv.*, m. 186-7°; *Me ether*, m. 121-2°; *Bz deriv.*, m. 157°; all 3 derivs. are insol. in alkali or alkali carbonate. Condensation of a mixt. of II and III with P₂O₅ yields tarry or resinous substances only. Dissolving IV in strong KOH soln. and refluxing on a sand bath for 5 hrs. leaves the major part of IV unchanged; only a small quantity was decompd., yielding a faintly yellow, liquid compd., whose semicarbazone m. 175-6°. By fusion of IV with KOH at 190-200° for 10 min., after dissolving in H₂O and acidifying with HCl, a compd. (V), m. 230°, was obtained, which probably is a dehydrogenated coumarin deriv. It dissolves in alkali and alkali carbonate with yellow color, gives a light green fluorescence in concd. H₂SO₄, but no color with FeCl₃; its *Bz deriv.*, m. 195°, gives a grass-green fluorescence with concd. H₂SO₄. Besides V, BzOH was isolated from the KOH fusion product. Concd. H₂SO₄ was added to a mixt. of I and II with cooling; after 36 hrs. a N-contg. compd. was isolated, m. 290°, insol. in org. solvents, sol. in concd. H₂SO₄ and alkali. Sapon. of this with 15% KOH yielded IV, identified by its m. p. and its *Ac deriv.* 3,4-Tetrahydrobenzo-7-methylcoumarin (50% from 4 g. *m*-MeC₆H₄OH, 6.5 g. III, and 25 cc. concd. H₂SO₄ with cooling), m. 119°, sol. in H₂SO₄, insol. in strong, boiling NaOH. 3.2 g. α -naphthol, 4.2 g. II¹, and 6 cc. concd. H₂SO₄ gave 3,4-tetrahydrobenzonaphthocoumarin (VI) in 100% yield, m. 190°, sol. in H₂SO₄ with yellow color and sea-green fluorescence, insol. in alkali, gives no color with FeCl₃; *NO₂ deriv.* (from 1 g. VI and 1 cc. HNO₃ in AcOH), yellow, m. 244°. By heating a mixt. of 4 g. 1,3,5-(HO)₃C₆H₃, 6 g. Et 5-methylcyclohexanone-2-carboxylate (VII), 4 cc. AcOH and 27 g. fused ZnCl₂ at 115° for 5 hrs., 75-80% of 3,4-tetrahydro-4'-methylbenzo-5,7-dihydroxycoumarin was obtained, m. 264-6°, sol. in warm alkali, gives a yellow color without fluorescence in H₂SO₄, and no color with FeCl₃. 3,4-Tetrahydro-4'-methylbenzo-5-methyl-7-hydroxycoumarin (75% from 3 g. VII, 2 g. 1,3,5-(HO)₃C₆H₃Me, and 10 cc. concd. H₂SO₄), m. 249°, sol. in NaOH and concd. H₂SO₄ with yellow color, gives no color with FeCl₃. 2.5 g. 1,2,3-(HO)₃C₆H₃ and 3.7 g. VII treated with 10 cc. concd. H₂SO₄ gave 4.8 g. of 3,4-tetrahydro-4'-methylbenzo-7,8-dihydroxycoumarin, m. 231°, sol. in alkali, gives no color with FeCl₃, sol. in H₂SO₄ with yellow color and emerald-green fluorescence. G. S.

Color and chemical constitution. XXIV. A complete investigation of the triphenylcarbinol or "aniline" dyes. JAMES MORR. *Trans. Roy. Soc. S. Africa* 17, No. 1, 51-60; cf. *C. A.* 22, 3164.—A complete series of 23 diphenyl- and triphenylcarbinol dyes has been prepd. and their absorption bands measured. They give in all 75 bands which M. explains in terms of chem. constitution as modified by varying H-ion concns. The

reference compd. is $(p\text{-HOC}_6\text{H}_4)_2\text{CHOH}$. By use of factors, 1.008 for NH_2 , when it replaces a ring OH, 1.058 for NMe_2 , and 1.025 for Ph for H of CHOH , calcd. results agree with the observed within 0.25% with 11 compds., all that can exist in a particular group; *i. e.*, aminohydroxy-, diamino-, dimethylaminohydroxy-, aminodimethylamino-, tetramethyldiaminobenzohydrols, benzaurin, aminofuchson, Doebner's violet, dimethylaminofuchson, dimethylaminofuchsonium chloride and malachite green. Ten, *i. e.*, all the possible triauxochrome triphenylcarbinols of this series were compared with the diauxochrome diphenylcarbinols and all have one of their bands almost coincident with the band of the corresponding di-Ph compd. The tri-Ph compds. employed were aurin, parafuchsin, crystal violet, aminobenzaurin, diaminofuchson, dimethylaminobenzaurin, tetramethyldiaminofuchson, dimethylparafuchsin, tetramethylparafuchsin, dimethyldiaminofuchson. M. maintains the close relationships in absorption spectra are due to the fact that electron movements causing color are (1) the same for 3-ringed sym. compds. as for 2-ringed substances with the same auxochromes, (2) nearly the same in 3-ringed substances with only 2 sym. auxochromes, (3) similar but perturbed when inactive auxochromes have different effects, (4) still more dissimilar when active auxochromes are different, *i. e.*, unsym. When 3 rings contg. the same auxochromes are present, the effect is due to only 2 of them, the other remaining almost inactive. Electronic movements causing high color cannot take place unless there is a balance or competition between 2 or more positive centers for a single electron. When 1 of the amino groups is fully ionized by mineral acid it behaves almost as if it were totally absent.

Chloro derivatives of acetylene. MARTHE VINCENS. *Rev. chim. ind.* 37, 224-7, 258-60, 291-3(1928).—A review of the manuf., properties and uses of these products.

P. THOMASSET

Addenda to the investigation of the half-hydrogenation of the acetylene union and the dependence of the geometrical configuration of the resulting ethylene compounds on the reaction velocity. ERWIN OTT, WITH FERDINAND SCHURMANN. *Univ. Münster i. W.* *Ber.* 61B, 2119-23(1928); cf. *C. A.* 21, 2000.—It had repeatedly been observed that in the half-hydrogenation of C_2H_2 derivs. under conditions leading to the highest possible reaction velocity the course of the reaction becomes non-uniform, a part of the C_2H_2 compd. remains unchanged and a part of the C_2H_4 deriv. formed is further hydrogenated to an C_2H_6 compd.; with a slower reaction velocity this phenomenon almost completely disappears and there is a continuously increasing sharper delimitation between the rapid hydrogenation of the acetylenes to the ethylenes and the much slower further hydrogenation of the ethylenes to the ethanes. These observations are explained by the Le Chatelier principle, much more heat being evolved in the 1st than in the 2nd reaction. Conversely the appearance of non uniformity in the course of the reaction may be taken as a direct measure of an increase in reaction velocity. If the hydrogenation of tetramethylbutinediol (I) is considered from this point of view the order given in the earlier paper for the velocities obtained with different catalysts is convincingly confirmed: (1) The non-uniformity appears with Pd only when the catalyst, after the pptn. of the metal on the carrier, has not come into contact with air; (2) with colloidal Pd there is no non-uniformity, nor with Ni animal charcoal; (3) non-uniformity is especially marked with Pt sponge (cf. Salkind, *C. A.* 21, 2459). Since the appearance of this earlier paper, Roth and Muller have repeated the detn. of the sp. heats of combustion of the most important compds. used as examples, with the following results: diphenyldiacetylene 9769 ± 2 , *trans-trans*-diphenylbutadiene 9841 ± 3 , *cis-cis*-diphenylbutadiene 9864 ± 2 , *cis-trans*-diphenylbutadiene (liquid) 9970 ± 4 cal./g.; these values confirm the order of their heats of formation which had been drawn up on the basis of the hydrogenation expts. and of the Stohmann rule. With an isostilbene from Ott's lab. they obtained a value (9800 kg. cal./g.) 15 kg. cal. lower than with a sample prepd. by Stoermer by the rearrangement of stilbene in ultra-violet light. Three fractions of another sample prepd. by catalytic half-reduction of tolan, which showed practically the same light absorption (Ley) and refraction (v. Auwers) nevertheless gave different heats of combustion (Verkade), the thermochem. method in this case proving more sensitive than the optical methods in detecting lack of homogeneity in the prepn. This again shows that with high reaction velocities, such as are necessary to obtain isostilbene and not stilbene from tolan, the course of the reaction is non-uniform. Salkind's detn. of the configuration of the butenediols obtained by half-reduction of tetraphenylbutinediol are not in harmony with Werner's rule, which has again been found to hold for the tetra-Me compds. and whose range of applicability may perhaps be extended even further than has been done by W. himself. For a comparison of m. p. relationships between *cis-trans*-isomers of the aliphatic and the corresponding *o-* and

p-substituted C_6H_4 derivs. were prep'd. ω, ω' -tetramethyl-*p*- (II) and *o*-xylyleneglycol (III). II (80% from 3 mols. $MeMgBr$ with *p*- $C_6H_4Ac_2$), m. 140° . III (10 g. from 15 g. *o*- $C_6H_4(CO_2Me)_2$ and $MeMgBr$ in C_6H_6), m. 166° . The *p*- and *o*-tetraphenylxylyleneglycols, m. 169° and 198° , resp., the *trans*- and *cis*-tetramethylbutenediols $68-9^\circ$ and $76-7^\circ$, and the *trans*- and *cis*-dihenzoylethylenes 111° and 134° . C. A. R.

Addition reactions of the ethylene double bond with the formation of ethane compounds with two asymmetric carbon atoms produced by the addition process and the influence of the reaction velocity on the course of the reaction. ERWIN ORT, WITH A. BEHR AND R. SCHRÖTER. Univ. Münster i. W. Ber. 61B, 2124-42(1928).—For a detailed study of the relations between reaction velocity and the course of the reaction in addns. to an C_2H_4 double bond was chosen the hydrogenation of dimethylfumaric (I) and dimethylmaleic acids (II) in the form of their Na salts in H_2O and of the 2 stereoisomeric dimethylstilbenes (III) in various solvents. The results, as a whole, show an undoubted analogy, in the course of the reaction, with the addn. of halogens and HO groups, but with H the picture is much less disturbed by side reactions. They indicate quite clearly that reaction in a single direction is not the rule but the exception which can be attained only by the use of reaction velocities exactly defined by the rule of reaction stages. Furthermore, the ratio of the resulting *meso*- and *dl*-products can with the fumaroid compds. be widely varied by changing the reaction velocities but with the maleinoid compds. so far studied only very little. As had already been observed with the C_2H_2 compds. (preceding abstr.) it is much easier to increase the reaction velocity than to lower it below a certain limit which is soon reached. The appearance of non-uniformity of the course of the reaction opposes, in the sense of the Le Chatelier principle, the increase in velocity only very late, while a decrease in velocity is very soon entirely offset by the complete cessation of any addn. at all. Of *cis*- and *trans*-isomers the former are usually the lower melting, more sol. and more labile, *i. e.*, richer in free energy, and addns. to them proceed with the greater velocity; it is not possible sufficiently to lower this velocity without passing below the sharply defined limit of non-reaction. Whereas with I the ratio of *meso*- to *dl*-product varies widely according as Ni or Pd is used as catalyst, with II there is practically no difference. Contrary to the Stohmann rule, of the dimethylsuccinic acids (IV) the higher-melting *meso*-form is the one richer in energy (Verkade and Coops, Jr., C. A. 22, 2871). As all the present expts. were carried out in solns. in which no racemates but only equal quantities of the optical antipodes can be present the energy contents of the active antipodes must be used in comparisons with the *meso*-forms. Verkade found for the heat of combustion of /rotatory IV 4599.2-9.7 cal./g. (*dl* form, 4597.5), *i. e.*, considerably lower than the value (4607.7 at 15°) for the *meso* form. The latter is therefore formed in preponderating amount (86-14) from the rapidly reduced II and this ratio cannot be changed by altering the conditions. I under the conditions of most rapid hydrogenation (acid salt with the most highly active Pd-charcoal) at room temp. gives 61% *meso*- and 39% *dl*-IV; by using a neutral soln. the addn. velocity is considerably diminished and the ratio becomes 30-70. By raising the temp. to 80° a ratio of 58:42 can be attained with Zn dust-AcOH also. With Ni-animal charcoal the lowest limit of decrease in reaction velocity can be attained and the *dl*-IV made the sole product. With the 1 exception above, recourse was not had to raising the temp. because the two IV can be rearranged into each other by HCl at high temps. Such a rearrangement probably also occurs in neutral solns., not only has it been proved to occur with I-II but this observation has been made use of for the most advantageous method of prep'g. I from pyrocinchonic acid. With the III it was also possible to increase the reaction velocity by raising the temp. That the liquid diphenylbutane (V) is really the *dl*-form has been definitely proved for the 1st time by its prep'n. in optically active form. The heat of combustion of the *dl*-V was found by Verkade to be 10,106-10,098 cal./g., that of the *meso*-form (by Roth) 10,064-10,085 (to which must be added 24 cal. for the heat of fusion). Thermochem. investigation of the active V has not yet been possible and moreover the sample obtained ($[\alpha]_D^{19} 20.24^\circ$) was quite certainly still contaminated with the *dl* form. *cis*-III is hydrogenated with Pd-charcoal in Et_2O at 20° with extraordinary rapidity; that the prep'n. still contained about 10% of the *trans*-form was indicated very clearly by the unmistakable decrease in the velocity of absorption of the H when about 90% had been hydrogenated; the product contained 90% *meso*- and 10% *dl*-V. In the prep'n. of the active V from the α -chloroethylbenzenes (VI) by the Wurtz-Fittig synthesis, the *dl*-VI reacts more slowly than the active form and yields relatively more *dl*-V. *trans*-III with Pd- and Ni-charcoals at 20° yields *dl*-V almost exclusively. In boiling AcOH with Pd-BaSO₄ Schlenk and Bergmann (C. A. 22, 4495) obtained only *meso*-V, but as they give no yields and O. on repeating their work obtained 35% *dl*-V and moreover

found that the catalyst was completely poisoned after the hydrogenation the results are not wholly convincing; at 180° under 40 atm. the hydrogenation was quite incomplete (with *dl*-V as the sole product) although electrolytic H in a perfectly new steel tank was used. Similarly, although S. and B. obtained only *meso*-V (yield not given) by addn. of Na to *trans*-III and subsequent decompn. with alc., O. obtained 30% *dl*-V and the addn. was incomplete. With Na and alc. at $80-5^{\circ}$ the reduction of *trans*-III was rapid and complete and gave about equal parts of *meso*- and *dl*-V; at 4° there was practically no reaction. I decomp. $244-5^{\circ}$ on rapid heating in a preheated bath. Steinhilber has found that *dl*-IV crystallizes in the monoclinic, not rhombic system, the active acids in the rhombic, very probably holohedric system; *l*-IV, $a:b:c = 0.5332:1:0.4784$. *cis*-III, obtained along with the *trans*-isomer and PhCHMeCPh:CH_2 from $\text{MeCPh}_2\text{CH(OH)Me}$ by Meerwein's method, monoclinic holohedral crystals, m. 66° .
C. A. R.

Cupric compounds of some aminoazo and hydroxyazo derivatives. A. CREMONINI, Reale Univ. Bari. *Gazz. chim. ital.* 58, 372-9(1928).—When the N derivs. of $\beta\text{-C}_{10}\text{H}_7\text{-NHCH}_2\text{Ph}$ already described (cf. Ciusa and C., *C. A.* 22, 2565) are boiled in EtOH for some hrs. with $\text{NH}_3\text{-CuSO}_4$ Cu derivs. are pptd. Thus $\alpha,\beta\text{-C}_{10}\text{H}_6(\text{N:NPh})\text{NHCH}_2\text{Ph}$ (5 g.) in 95% EtOH (500 cc.) refluxed 6 hrs. with excess $\text{NH}_3\text{-CuSO}_4$ (21 g. CuSO_4 and 240 cc. of 25% NH_4OH), filtered, washed successively with boiling EtOH, dil. NH_4OH , water and EtOH, yields a brown Cu deriv. contg. 65.78% C, 3.59% H, 10.54–10.63% N and 19.87% Cu, which is insol. in ordinary solvents, is electrified by rubbing, takes fire with cold concd. HNO_3 and does not m. up to 320° . Treated in a similar way, $\beta,\alpha\text{-C}_{10}\text{H}_6(\text{NHCH}_2\text{Ph})\text{N:N}\text{C}_6\text{H}_4\text{NO}_2\text{-}p$ ppts. a rose-violet Cu deriv. contg. 65.72% C, 3.72% H, 1.34% O, 9.69% N and 19.53% Cu. A Cu salt of phenylazo- β -naphthylamine (I) was found to differ from that prepd. by Charrier and Beretta (*C. A.* 21, 1456) $\text{CuSO}_4\cdot 10\text{H}_2\text{O}$ (5.56 g.) in 25% NH_4OH (35 cc.) boiled 1 hr. with I (10 g.) in 95% EtOH (150 cc.), filtered hot, washed successively with boiling EtOH, 10% NH_4OH , water and EtOH, and the residue recrystd. from AcMe, yields *cupridiphenylazo- β -naphthylamine*, $\text{C}_{22}\text{H}_{14}\text{N}_6\text{Cu}$ (II), greenish black with metallic reflection, when pulverized is violet-red, m. 174° , gives a violet soln. in concd. H_2SO_4 , takes fire with concd. HNO_3 , decompd. into I and CuCl_2 by dil. HCl . II is decompd. by heating 4 hrs. at $250-60^{\circ}$, yielding PhNH_2 , NH_3 , CuO , specular Cu and a brown mass. The latter extd. with water yields $\alpha,\beta\text{-C}_{10}\text{H}_6(\text{NH}_2)_2$, and then extd. with EtOH yields 2-*N*-phenyl- α,β -naphthothiazole (III). The residue from these 2 extns when extd. with C_6H_6 , $\text{C}_6\text{H}_5\text{N}$, AcOH, AcMe, etc., gives fluorescent solns., characteristic of dinaphthazines, which give blue, red or brown colors with concd. H_2SO_4 , but from which no definite compds. could be isolated. When a soln. of II in any of the solvents is left exposed to air, the violet-red soln. becomes light yellow and deposits a greenish yellow substance contg. Cu. This transformation is most rapid in Et_2O and in any of the solvents it is accelerated by heating. The soln. contains III. Phenylazo- β -naphthol (10 g.) in EtOH (800 cc.) and $\text{NH}_3\text{-CuSO}_4$ (5 g. in 35 cc. NH_4OH) form *cupriphenylazo- β -naphthol* (IV), brown, m. 288° , can be crystd. from xylene, has chem. properties similar to those of II, *e. g.* with concd. HNO_3 , dil. acids and on standing in an org. solvent. A crit. discussion of the results in conjunction with the work of other investigators leads to the conclusion that the formulas of II and IV are:

in which the Cu with secondary valences forms a hexacyclic nucleus. Photomicrographs of crystals of II and IV are reproduced.
C. C. DAVIS

The reaction of malononitrile with α -naphthoquinone. W. KASTING. ARTI-A. G. BARMEN. *Z. angew. Chem.* 41, 745-8(1928).—When $\text{H}_2\text{C}(\text{CN})_2$ (I) is allowed to act on α -naphthoquinone (II) in H_2O , a deep blue color develops (*C. A.* 22, 4315). The nature of the resulting dye is investigated in this study. The blue color also appears when the reaction takes place in alc. In Et_2O , reaction only occurs in the presence of H_2O . No reaction occurs in acid soln., while in alk. soln. a green color is formed. By acidifying the blue, neutral soln., a red, amorphous substance is pptd. By adding alkali to the blue soln., the color changes to green. Neither the blue nor the green compd. could be isolated from these solns. without decompn. The structure (III) is attributed to the blue dye, because its strong color, its soly. in H_2O , and the stability of its NH_4 salt and metallic salts are supposedly best explained by assuming that, with the aid of partial valencies, an inner complex salt is formed by the interaction of the 2 NH groups of IV. This latter is an intermediate product in the reaction and originated from V, the primary reaction product. Accordingly, the formula VI is given to the NH_4 salt

of β - α' -naphthoquinonyl- β -iminopropionitrile, prepd. by dissolving equimol. quantities of I and II in Et_2O and introducing dry NH_3 gas. The violet ppt. is pure after washing with Et_2O , sol. in H_2O and EtOH with a deep blue color, sparingly sol. in Et_2O , decolorized by H_2S , NaHSO_3 or $\text{K}_2\text{Cr}_2\text{O}_7$. It dyes wool in a neutral soln. or a soln. slightly acidified with AcOH , but the color is not stable. *HCl addn. product* (VII), from VI by dissolving it in cold H_2O and adding HCl . The red ppt. is dissolved in Et_2O , and the ether evapd. in a desiccator contg. HCl . It forms rust-brown scales, stable in a dry state. β - α' -Naphthoquinonyl- β -iminopropionitrile (III), from pulverized VII by allowing it to lie in humid air till it has a pure, blue color, washed with Et_2O , m. above 250° (decompn.). *Ag salt*, brownish black powder of metallic glitter, sparingly sol. in H_2O with blue color, sol. in NH_4OH . G. SCHWOCH

Fission of the furan ring. III. R. TAKAMOTO. Tokyo Imp. Univ. *J. Pharm. Soc. Japan* 48, 686-92(1928).—In papers I (*C. A.* 21, 3362) and II (*C. A.* 22, 3162), T. has shown that furan derivs. with a basic side chain give primary alcs. by fission of the ring by catalytic reduction and the resulting alcs. after conversion into mono-Br substitution products can be converted into higher-membered cyclic compds. by means of an alkali. Thus, $\text{C}_4\text{H}_5\text{OCH}_2\text{NH}_2$ was converted into $\text{HO}(\text{CH}_2)_4\text{NH}_2$ and then into piperidine, and $\text{C}_4\text{H}_5\text{O}(\text{CH}_2)_2\text{NH}_2$ was changed into $\text{HO}(\text{CH}_2)_6\text{NH}_2$ and then into $(\text{CH}_2)_6\text{NH}$. In this paper a new compd. *furylpropylamine* (I) (b_{20} , $34-5^\circ$, b_{714} $172.5-30^\circ$, *picrate*, m. $165-6^\circ$; *picrolonate*, m. $231-2^\circ$) was found to give the same series of reactions. Reduction of $\text{C}_4\text{H}_5\text{OCH}:\text{CHCH}:\text{NOH}$ with Na-Hg gave I, which on reduction with H_2 and PtO_2 , with FeCl_2 as a promoter, gave almost quant. *tetrahydrofurylpropylamine* (II), b_{20} $39-40^\circ$, b_{714} $186-7^\circ$. *Picrate*, m. $136-7^\circ$. *Picrolonate*, m. $176-7^\circ$. Further reduction of II with PtO_2 and a H_2 pressure of 1.5-2.0 atms. resulted in the fission of the ring and gave η -hydroxyheptylamine (III) $\text{HO}(\text{CH}_2)_7\text{NH}_2$, b_{15} $130-1^\circ$. *Chloroplatinate*, m. $165-6^\circ$. III and PBr_3 gave η -bromoheptylamine- HBr , m. $84-5^\circ$, which with an alkali gave the free base (IV), b_{100} $161-2^\circ$, b_{25} $29-30^\circ$. *Picrate*, m. $102-3^\circ$. Heating of IV, with satd. aq. KOH gave heptamethylenimine (V), $(\text{CH}_2)_7\text{NH}$, b_{25} $43-4^\circ$, b_{714} $174-5^\circ$. *Chloroplatinate*, m. $218-9^\circ$; *guaiacolate*, m. $138-9^\circ$; *N-Bz deriv.* b_{25} $162-25^\circ$; *NO deriv.* (VI), b_{25} $108-9^\circ$. Reduction of VI with PtO_2 and H_2 gave *N-aminoheptamethylenimine* $b_{15.5}$ $54-5^\circ$. *Chloroplatinate*, m. $207-8^\circ$. NAO UYEH

Condensation of pyrrole with aliphatic ketones. TH. SABALITSCHKA AND H. HAASE. *Arch. Pharm.* 266, 484-92(1928).—By the more or less modified procedures of v. Baeyer, more particularly of Dennstedt and Zimmermann, the following compds. of pyrrole with various aliphatic ketones have been prepd. and characterized. Thus, with AcMe the compd.: tetraacetone-tetrapyrrole, $\text{C}_{28}\text{H}_{24}\text{N}_4$, m. 296° (darkening); with AcEt : tetraethylethylketone-tetrapyrrole, $\text{C}_{28}\text{H}_{24}\text{N}_4$, m. 149° (Dennstedt and Zimmermann, 142°); *tetradieethylketone-tetrapyrrole*, m. 208° ; *tetra-*

methylpropylketone-tetrapyrrole, m. 226°; *tetraethylpropylketone-tetrapyrrole*, m. 219°; *tetramethylbutylketone-tetrapyrrole*, m. 193-4°; *tetraethylisobutylketone-tetrapyrrole*, m. 199°; *tetraethylbutylketone-tetrapyrrole*, m. 205-6°; *tetramethylhexylketone-tetrapyrrole*, m. 178°. The compd. with AcEt yields with CrO_3 in aq. AcOH maleinimide. Distd. with Zn dust the AcMe compd. gave a substance volatile with steam, b. about 175°, reddening on standing, and having the compn. $\text{C}_7\text{H}_{11}\text{N}$. W. O. E.

d-Borneol and cis-terpinol from the distillation residues of turpentine oil-sulfate. WALTER QVIST. *Chemisch-tech. Inst. Akad. Abo, Finland. Biochem. Z.* **197**, 476-81(1928). S. MORGULIS

Synthesis in the pyrazolone series. Action of thiosemicarbazide and semicarbazide on ketonic esters. II. SATIS, CHANDRA DE AND NIRODE CHANDRA DUTT. *Dacca Univ. J. Indian Chem. Soc.* **5**, 459-65(1928).—Continuing their expts. on condensation of carbazides with ketonic esters (*C. A.* **21**, 2128), D. and D. studied the interaction of $\text{OC}(\text{NH}_2)\text{NHNH}_2$ (I), $\text{SC}(\text{NH}_2)\text{NHNH}_2$ (II), and their 4-substituted derivs. with $\text{BzCH}_2\text{CO}_2\text{Et}$ (III), and $(\text{EtO}_2\text{CCAcH})_2$ (IV), resp.; further on, the reaction between 4-substituted carbazides and $\text{AcCH}_2\text{CO}_2\text{Et}$ (V). In none of these reactions could the intermediate hydrazone be isolated. The condensation of IV with carbazides yielded bispyrazolones exclusively. To III in alc. was added 1 mol HCl salt of II in H_2O . The mixt. was shaken, 1 mol. AcONa added, and allowed to stand for 2 days. Solid 3-phenylpyrazolone-1-thiocarbamide (VI) seps out, m. 161° after recrystn. By heating III in alc. with 1 mol. of the HCl salt of II in a small quantity of AcONa, VI was obtained in an easier way. 4,4-Dibromo-3-phenylpyrazolone-1-thiocarbamide (from VI and an excess of Br in AcOH), light orange-red, shrinks at 130° with slow liberation of Br. NaNO_2 with VI in AcOH gives 4-isontroso-3-phenylpyrazolone 1 thiocarbamide, yellow, m. 174°, of acid reaction, sol in alkali. 3-Phenylpyrazolone-1-thiocarbophenylamide (from $\text{PhNHCS}(\text{NHNH}_2)$ and 1 mol III in EtOH), m. 127°. 3-Phenylpyrazolone-1-thiocarbo-p-tolylamide (from *p*- $\text{MeC}_6\text{H}_4\text{NHCS}(\text{NHNH}_2)$ and 1 mol III in EtOH), m. 106°. 3-Phenylpyrazolone-1-thiocarboethylamide (from $\text{EtNHCS}(\text{NHNH}_2)$ and III in EtOH), m. 136°. 3-Phenylpyrazolone-1-carbamide (VII), m. 179°, was prepd. similarly to VI. When heated in a sealed tube with HCl and EtOH at 120-30° for several hrs., VII is transformed to 3-phenylpyrazolone. From VII and Br in AcOH, there results the 4,4-di-Br deriv., m. 144°. 4-Isonitroso deriv. (from VII and NaNO_2 in AcOH), yellow, m. 204°. By condensation of IV with 2 mols I in aq. alc. AcONa, 4-bis-3-methylpyrazolone-1-carbamide, m. 128°, was prepd. At its m. p., it is at once converted into bis-3-methylpyrazolone, m. 290°. II heated with 1 mol IV in EtOH yielded 4-bis-3-methylpyrazolone-1-thiocarbamide, m. 197°. 4-Bis-3-methylpyrazolone-1-thiocarbophenylamide (from $\text{PhNHCS}(\text{NHNH}_2)$ and 0.5 mol IV), m. 191°. 4-Bis-3-methylpyrazolone-1-thiocarbo-p-tolylamide (from *p*- $\text{MeC}_6\text{H}_4\text{NHCS}(\text{NHNH}_2)$ and 0.5 mol IV), m. 201.2°. 4-Bis-3-methylpyrazolone-1-thiocarboethylamide (from $\text{EtNHCS}(\text{NHNH}_2)$ and 0.5 mol IV in EtOH), m. 191°. 3-Methylpyrazolone-1-thiocarbophenylamide, m. 117°, was prepd. from $\text{PhNHCS}(\text{NHNH}_2)$ and V by heating in EtOH. Similarly were obtained 3-methylpyrazolone-1-thiocarbo-p-tolylamide (from *p*- $\text{MeC}_6\text{H}_4\text{NHCS}(\text{NHNH}_2)$ and V), m. 121°; and 3-methylpyrazolone-1-thiocarbomethylamide (from $\text{MeNHCS}(\text{NHNH}_2)$ and IV), m. 84°. G. SCHWOCH

Hydrogenation of the imidazole ring. E. WASER AND A. GRATSOS. *Univ. of Zürich. Helv. Chim. Acta* **11**, 944-64(1928).—Up to the present, attempts to reduce imidazole (I) and its derivs. directly to compds. richer in H have not been successful. W. and G. were unable to reduce catalytically I, histidine, 2,4,5-trimethylimidazole, benzimidazole or lysidine, but did reduce lophine (II) and amarine (III). In the prepn. of I they found that the use of $\text{C}_{15}\text{H}_{16}$ as heat carrier in the decarboxylation of imidazoledicarboxylic acid increased the yield from 50 to 80% (cf. *C. A.* **20**, 1067). The time required for the hydrogenation of II was shortened (1) by careful purification of II, (2) by frequent activation of the catalyst by shaking with air for a few min., and (3) by the addn. of a little hydrolophine (IV). In the presence of a few mg. of IV, 23 g. II could be hydrogenated in about 190 hrs. To 1.028 g. II dissolved in 30 cc. very pure glacial AcOH was added 0.758 g. Pt black. The mixt. was shaken in an atm. of H at room temp. and under a slight excess pressure (50 cm. H_2O column). During the 14 hrs. of hydrogenation the catalyst was activated 3 times. The H taken up corresponded to 10 mols. H_2 per mol. of II. The product was the acetate (V) of IV, m. 162.3° (cor.). When left in a vacuum at 100-20° for several hrs. V was converted into IV. IV may also be obtained from the AcOH soln. of V by cooling, adding KOH until alk., and filtering off the pptd. IV. IV, m. 211.3° (cor.), can be distd. without decomposition. Its alc. soln. was strongly alk. to litmus. The following derivs. were prepd.: HCl salt, m. 208-70°; HBr salt, m. 290.2°, chloroplatinate, yellowish red, m. 251-2°; pic-

rate and picrolonate did not crystallize well; *styphnate*, yellow, m. 201–2°; *nitroso deriv.*, m. 175° (decompn.), when warmed with alc. HCl on water bath gave the HCl salt. IV on careful oxidation with CrO₃ gave C₆H₁₁CONH₂. From the product of the reaction of 14 g. V with 150 cc. HNO₃ (d. 1.4) was obtained 2 g. adipic acid, 0.5 g. of a yellow solid, m. 249.5–51° and contg. 2 NO₂ groups, and a red oil which did not crystallize and decompd. on distn. IV when ozonized gave products of undetd. constitution. When IV in CCl₄ was titrated with Br-CCl₄, 1 mol. Br was added, giving the HBr salt (VI) of IV, yellow, m. 287°. With a large excess (3 mols.) of Br, the product was *hydrolophine perbromide-HBr* (VII), orange, m. 162°. VII was very labile. On addn. of petroleum ether contg. unsatd. compds., the orange color disappeared at once and VI was pptd. Heated at 70–220°, VII lost Br, giving VI. *Warmed on the water bath with alc. KOH, VII was converted into IV. By the action of Br on II no well-characterized Br addn. or substitution product could be obtained. III in CHCl₃ added 3 atoms Br per mol., giving *amarine perbromide-HBr* (VIII), dark red, m. 122° (decompn.). VIII when treated with impure petroleum ether gave the HBr salt (IX) of III, m. 264° (uncor.). Heated slowly at about 220°, VIII gave IX and 2 mols. HBr. VIII when warmed with 10% alc. KOH on the water bath was converted into II (86% yield). This affords a new method for prep. II. When 35 g. III was reduced with H and Pt black in the presence of a small quantity of already hydrogenated material, 1 mol. III took up 9.72 mols. H₂ in about 320 hrs. The product (m. 150–80°) was a mixt. which could be easily sepd. into its components by Me₂CO. From the hot soln. in Me₂CO crystd. hydroamarine (X), m. 171–2° (cor.). Its alc. soln. gave a strongly alk. reaction. X did not react with KMnO₄ or Br. The other product, obtained by evapn. of the Me₂CO mother liquor from X, was IV. The following derivs. of X were prepd.: *HCl salt*, sinters 292°, m. 302° (decompn.); *HBr salt*, m. 296° (decompn.); *acetate*, m. 152–3°; *chloroplatinate*, yellow, m. 216.5–7°, loses 4H₂O at 110°; *styphnate*, yellow, m. 168.5–9.5°.

LOUISE KELLEY

Oximes of *N*-methyl-2-benzothiazolone and of *N*-methyl-2-quinolone. KARL FUCHS AND EGON GRAU AUG. Univ. Wien. *Ber.* 61B, 2194–7(1928).—The oximes of a no. of heterocyclic ketones cannot be prepd. by the usual methods (treatment of the ketone or thioketone with NH₂OH). Recently F. and G. showed that hydrazones of *N*-methyl-2-quinolone (I) are readily obtained from 2-iodoquinoline-MeI (II) (C. A. 22, 1358) and they now find that with NH₂OH it readily yields the *oxime* (III) of I. 2-Iodobenzothiazole-MeI (IV) likewise yields *N*-methyl-2-benzothiazolone *oxime* (V). III dissolves in dil. acids, without color, forming *N*-methyl-2-quinolyldihydroxylamine salts, and is reprecipitated by alkalis. It is hardly attacked by long boiling with concd. HCl and dissolves without change in cold concd. H₂SO₄; on long heating at 90° in concd. H₂SO₄ it is apparently sulfonated in the C₆H₄ nucleus, diln. with H₂O giving after a time white crystals sol. in alkalis with yellow color. III dissolves in hot alkalis with reddish yellow color and seps. unchanged on cooling. It can be reduced to 2-aminoquinoline-MeI with SnCl₂ in concd. HCl. IV (about 85% from 2-chlorobenzothiazole and MeI at 80°), Cu-colored. V (yield, 70%), faintly yellow, m. 202–3° *in vacuo* (effervescence) sol. in C₆H₅N with yellow color. III, intensely yellow, m. 180.5–1.5° *in vacuo* (effervescence); *HCl salt*, m. 230–2° (decompn.) *in vacuo*; *perchlorate*; *Na salt*, orange-yellow, immediately decompd. into the free III and NaOH by H₂O. C. A. R.

A simplified method for preparing substituted μ -methylbenzothiazoles and their conversion into new heterocyclopolyimethine dyes. W. KÖNIG, with P. SEIDEL AND G. STÜMMER. Sächs. Techn. Hochschule Dresden. *Ber.* 61B, 2065–74(1928).—In connection with certain investigations on color and constitution it was desired to have dyes of the types I and II in which the C₆H₅ ring of the benzothiazolyl residue is substituted. The starting materials were the salts (perchlorates, iodides, bromides, etc.) of the hypothetical bases 5-chloro- (III), 6-chloro- (IV), 6-bromo- (V), 6-methoxy- (VI),

6-methoxy-5(?)-chloro- (VII) and 6-chloro-4-methyl-[1,2-dimethylbenzothiazolium hydroxide] (VIII). The parent tertiary cyclamines of these quaternary salts were prepd. by the usual methods (for IV, V and VI by oxidation of the corresponding thioacetanilides by Jacobson's method, for III by acetylating reduction of [4,2-Cl(O₂N)C₆H₃]₂S₂).

(XI)

Later it was found that a no. of these γ -methylbenzothiazoles can be prepd. much more conveniently from the aq. alk. solns. of *o*-aminophenyl mercaptans obtained by treating salts of aromatic primary amines with S₂Cl₂. These solns. with Ac₂O give the thiazoles directly. The bases are in all cases smoothly converted into the quaternary salts by Me halides or Me₂SO₄; the products obtained with the latter are converted into the well-crystd. perchlorates with NaClO₄. In some cases the corresponding methylene bases (IX) were isolated in pure cryst. form and in part converted into the characteristic CS₂ derivs. (X) whose fine structure is best represented by XI, which represents them as betaine-like salts with a colored benzothiazolium cation and a likewise colored dithioacetate anion, mutually combined intramol. As regards the change in color produced by C₆H₅ ring substituents in I and II, it was found that halogen atoms in the *p*-position to the N produce a quite distinct positive shift in the color tone of the sym. I. Cl in the 6-position (*m* to N, *p* to S) is somewhat more weakly bathochromic. MeO groups in the *p*-position to the N produce a still more marked positive shifting. Me groups in the 7- or 7'-position (adjacent to the N) are weakly hypsochromic. The absorption curves of all these new thiocyanines greatly resemble those of thiazole purple; they show in the visible spectrum a strong band which in thin layers has 2 sharp max., the more persistent lying towards the longer wave lengths. The simplest *strepto*-monovinylene-thioflavines (II) are influenced in the same sense, although not so markedly, by substituents on the C₆H₅ ring. These dyes all color tannated cotton more or less violet-red; their absorption curves have in the visible region only a single, relatively broad, non-resolvable band. 5-Chloro-2-methylbenzothiazole (40% from [4,2-Cl(O₂N)C₆H₃]₂S₂ slowly treated under a reflux with Ac₂O and Zn dust), m. 62°, methiodide, light gray, m. 212°; perchlorate, m. 192°; methylene base, from the methiodide in Me₂CO suspension with concd. NaOH, yellow, m. 158°. 6-Chloro-2-methylbenzothiazole (30% from *p*-ClC₆H₄CSNHAc in NaOH with K₃Fe(CN)₆ or 20% from the product obtained from PhNH₂·HCl with S₂Cl₂ slowly heated to 70° in aq. alc. NaOH (in the presence of Na₂S₂O₃), rapidly filtered from the Na₂SO₃ and allowed to stand overnight with Ac₂O), m. 81°; methiodide, pale green, m. 222°, methobromide, m. above 270° (decompn.), perchlorate, m. 198°; methylene base, yellowish, m. 145°; CS₂ addn. product, orange, decomp. above 275°. 6-Bromo-2-methylbenzothiazole (25% from *p*-BrC₆H₄CSNHAc) methiodide, m. 208°; perchlorate, m. 216°; methylene base, yellowish, m. 148°. 6-Methoxy-2-methylbenzothiazole, b₂₀ 170°, b₂₅ 176°, b. 284° (slight decompn., assuming an unpleasant odor and strong green fluorescence); picrate, m. 176°; methobromide, m. 248° (decompn.); methiodide, m. 228°; perchlorate, m. 196°; methylene base, yellowish, m. 135°; CS₂ addn. product, yellow, m. 239° (decompn.). On distg. the above benzothiazole there remained a small quantity of cryst. 6-methoxy-5(?) -chloro-2-methylbenzothiazole, m. 69°; methiodide, m. 215°. 6-Chloro-2,4-dimethylbenzothiazole (12 g.

from 30 g. of the product obtained from *o*-MeC₆H₄NH₂·HCl and S₂Cl₂), m. 79°; methiodide (obtained in only 20% yield), m. 244°. 3-Methyl-2-*p*-dimethylaminobenzylidene methyl-6-chlorobenzothiazolium bromide, from *p*-chlorodimethylbenzothiazole-MeBr refluxed with 1 mol *p*-Me₂NC₆H₄CHO and the least possible quantity of Ac₂O, violet, m. 249°, shows in the bluish red alc. soln. an absorption band at 537μ, dissolves in concd. H₂SO₄ with yellow color, is decolorized by concd. alkalis. 6-MeO analog, violet, m. 255°, has an absorption max. in alc. at 521μ. 5(?) -Chloro-6-methoxy iodide, dark red, m. 214°, with an absorption max. in EtOH at 534μ. 3,4-Dimethyl-2-*p*-dimethylaminobenzylidenemethyl 6-chlorobenzothiazolium iodide, red-violet, m. 234°, with an absorption max. at 534μ. 1,1'-Dimethyl-6,6'-dichloro-*strepto*-monovinylene-2,2'-thiocyanine iodide, from 5-chloro-2-methylbenzothiazole-MeI refluxed with 1 mol HC(OEt)₃ in a sufficient quantity of Ac₂O for soln., needles with blue luster, decomp. above 270°, has a chief absorption band at 563μ and a secondary band at 526μ, is decolorized by excess of mineral acids and decompd. by much boiling NaOH. 5,5'-

Di-Cl analog, decomps. 286° , has absorption max. at 575 and 541μ . *6,6'-Dimethoxy perchlorate*, needles with steel-blue luster, decomps. about 290° , forms a deep blue alc. soln., shows a sharp main band at 628μ and a secondary band at 574μ . *5,5'-Dibromo iodide*, needles with steel-blue luster, decomps. 280° , with mag. in alc. at 574 (chief band) and 540μ . *1,1',7,7'-Tetramethyl-5,5'-dichloro iodide*, dark red needles with metallic luster, m. 243° , shows in alc. sharp bands at 562 and 529μ . C. A. R.

Sesamin. S. H. BERTRAM, J. P. K. VAN DER STEUR AND H. I. WATERMAN. Techn. Hochschule, Delft. *Biochem. Z.* 197, 1-7(1928).—Sesamin, according to its properties,

reactions and analyses, has the structure $3,4\text{-CH}_2\text{O}_2\text{C}_6\text{H}_3\text{CH}_2\text{OCH}(\text{CH}_3)_2\text{CH}(\text{CH}_3)_2\text{O}_2\text{CH}_2$. Its

$$\begin{array}{c} \alpha' \qquad \alpha \\ | \qquad | \\ \text{CH}_3-\text{CH}_2 \end{array}$$

 mol wt., $\text{C}_{18}\text{H}_{16}\text{O}_6$, is 312, m. 122.7° ; $[\alpha]_D^{25} 72.77^{\circ}$, heat of combustion 6565 cal./g., d. 1.307, soly. in alc. 0.27 g. at $20-3^{\circ}$ or 8.07 g. per 100 cc. at the boiling temp.

S. MORGULIS

Basic nitrogen compounds from Fushun shale tar. II. TAKASHI EGUCHI. *Bull. Chem. Soc. Japan* 3, 227-34(1928); cf. C. A. 21, 3197.—The light fractions from the Fushun shale tar consist chiefly of basic compds. of the pyridine series rich in α - and γ -alkyl derivs. By fractional distn., followed by a fractional crystn. of the picrates in alc., the following compds. were isolated: 4-Methylpyridine, completely miscible with H_2O , $b_{760} 145.45-547^{\circ}$, $d_4^{25} 0.9502$, $n 1.5029$, 1.4986, 1.5143, 1.5240 for D, C, F and G' at 25° , picrate, m. 167° . Oxidation with KMnO_4 gives isonicotinic acid. 3-Methylpyridine $b_{760} 144.17-4.18^{\circ}$, $d_4^{25} 0.9518$, $n 1.5038$, 1.4994, 1.5155, 1.5256 (picrate, m. 149°), gives the double salts. $(\text{C}_6\text{H}_7\text{N.HCl})_2\text{PtCl}_6$, m. 208° , $\text{C}_6\text{H}_7\text{N.HCl.AuCl}_4$, m. 187° , $\text{C}_6\text{H}_7\text{N.HCl.HgCl}_2$, m. 145.6° , $\text{C}_6\text{H}_7\text{N.HCl.2HgCl}_2$, m. 146° , $\text{C}_6\text{H}_7\text{N.HCl.3HgCl}_2$, m. 170° , oxidizes to nicotinic acid. 2,3-Dimethylpyridine, sol. in 10 parts H_2O at 23° , $b_{760} 160.7^{\circ}$, $d_4^{25} 0.9419$, $n 1.5057$, 1.5014, 1.5172, 1.5272 (picrate, m. 188°), oxidizes to quino-
 line acid. 2,5-Dimethylpyridine, sol. in 12 parts H_2O at 23° , $b_{760} 156.82-88^{\circ}$, $d_4^{25} 0.9261$, $n 1.4982$, 1.4939, 1.5095, 1.5194 (picrate, m. 167° ; $(\text{C}_7\text{H}_9\text{N.HCl})_2\text{PtCl}_6$, m. 211° , $\text{C}_7\text{H}_9\text{N.HCl.6HgCl}_2\cdot\text{H}_2\text{O}$, m. 203°), oxidizes to isonicotinic acid. 3,5-Dimethylpyridine, $b_{60} 171.6^{\circ}$, $d_4^{25} 0.9385$, $n 1.5032$, 1.4988, 1.5146, 1.5244 (picrate, m. $170-2^{\circ}$), oxidizes to nicotinic acid. 3,4-Dimethylpyridine, sol. in 20 parts H_2O at 22° , $b_{760} 178.82^{\circ}$, $d_4^{25} 0.9537$, $n 1.5099$, 1.5055, 1.5209, 1.5305 (picrate, m. 163° ; $(\text{C}_7\text{H}_9\text{N.HCl})_2\text{PtCl}_6$, m. 276° ; $\text{C}_7\text{H}_9\text{N.HCl.3HgCl}_2\cdot 2\text{H}_2\text{O}$, easily sol. in hot, slightly in cold H_2O , m. $150.5-131^{\circ}$; $\text{C}_7\text{H}_9\text{N.HCl.AuCl}_4$, m. 187°), oxidizes to cinchomeronic acid. 2,4-Methylpyridine, slightly sol. in H_2O , $b_{760} 179.80^{\circ}$, $d_4^{25} 0.9130$, $n_D^{25} 1.4953$ (picrate, m. 178.80°), oxidizes to lutidinic acid. 2,3,6-Trimethylpyridine, sol. in 32 parts H_2O at 26° , $b_{760} 172.88-290^{\circ}$, $d_4^{25} 0.9220$, $n 1.5018$, 1.4976, 1.5133, 1.5232 (picrate, m. $147-8^{\circ}$; $\text{C}_8\text{H}_{11}\text{N.HCl.AuCl}_4$, m. 139° , $(\text{C}_8\text{H}_{11}\text{N.HCl})_2\text{PtCl}_6$, blackens at 220° ; $\text{C}_8\text{H}_{11}\text{N.HCl.6HgCl}_2$, m. 165°), oxidizes to 2,3,6-pyridinetricarboxylic acid.

A. L. HENNE

The Döbner reaction. GINO CARRARA. Lab. Lepetit Farmaceutici, Garressio (Italy). *Gazz. chim. ital.* 58, 309-17(1928).—The explanation given by Döbner (cf. *Ann.* 240, 270; 249, 98; *Ber.* 25, 2864; 29, 59; 32, 2276), for the reaction between aromatic aldehydes, amines and AcCO_2H is unsatisfactory in several ways, particularly since it does not explain the low yields of quinoline- γ -carboxylic acids or the high yields of resins. Expts. on the analysis of such a resin are described, the results leading to a hypothesis of the reaction which takes place. AcCO_2H (40 g.) added dropwise to a boiling mixt. of PhNH_2 (67 g.), pure BzH (76 g.) and 95% EtOH (1.2 l.), refluxed 5 hrs., the EtOH distd. off, filtered, the residual resin washed with 95% EtOH (500 g.), yields approx. 100 g. of a viscous, brown resin. This resin boiled for 1 hr. with aq. Na_2CO_3 (40 g. in 700 cc. water), cooled, decanted, the decanted liquor clarified with animal charcoal, made acid with HCl , filtered, the residue dissolved in boiling dil. HCl (50 cc. concd. HCl + 100 cc. water), again purified with animal charcoal, filtered, let stand 24 hrs., the ppt. boiled with aq. Na_2CO_3 (7 g. in 100 cc. water), the soln. purified with animal charcoal, filtered, the filtrate acidified with dil. HCl , and the ppt. recrystd. from EtOH , yields about 3 g. of phenylquinolinecarboxylic acid. Fresh resin (*loc. cit.*) (500 g.) (after treatment with alkali as described above) boiled 1 hr. with concd. HCl (1.25 kg.) and water (2 kg.), decanted, the liquid boiled with animal charcoal (30 g.), filtered, the residue treated with HCl (500 g.), dild. with water (1 l.), the filtrates united, let stand 24 hrs., the ppt. (approx. 700 g.) suspended in water (1 l.), warmed, made alk. with 10% NaOH , the crude base (100-120 g.) sepd., dried, distd. *in vacuo* (204° at 65 mm.), and the crystd. distillate recrystd. from boiling 80% EtOH , yields 80-90 g. of

PhCH_2NHPh . The latter (20 g. in 50 cc. CHCl_3) treated with cold Br in CHCl_3 (21 vol.-% Br) until an orange color, absorbs 18 g. of Br, and by distn. of the CHCl_3 and recrystn. of the residue from AcOH yields bromobenzylaniline, m. 168° (the same as reported in the literature). With dil. alkalis it eliminates HBr, with formation of a compd., which m. 53° , and which is to be investigated. PhCH_2NHPh (20 g.) in AcOH (200 cc.) treated during 1 hr. with NaNO_2 (15 g.), water (200 cc.) added dropwise and the ppt. recrystd. from AcOH, yields 23 g. of the NO deriv., m. 59° (the same as reported in the literature). AcCO_2H and PhCH:NPh (equimol. parts) let stand 24 hrs. in cold EtOH give a ppt. which, washed with EtOH and recrystd. by soln. in a min. of CHCl_3 , and addn. of MeOH or EtOH, yields $\text{CO.CO.NPh.CHPh.CH}_2$, m. 160° (cf. Skita and

Wulff, C. A. 21, 2882; Bodforss, C. A. 21, 2902). The latter (25 g.) boiled 12 hrs. with BzH (11 g.), PhNH_2 (9 g.), EtOH (300 cc.) and AcOH (50 cc.), the EtOH distd. off, dild. with water, let stand 24 hrs., decanted, the residue extd. several times with Na_2CO_3 , the ext. decolorized with animal charcoal, filtered, HCl (1:5) added, the ppt. washed with EtOH and purified by soln. in Na_2CO_3 , decolorization and pptn. with HCl, yields 6-7 g. of α -phenylquinoline- γ -carboxylic acid, m. $209-10^\circ$ (the same as reported in the literature). The formation of PhCH_2NHPh from Bz, PhNH_2 and AcCO_2H suggests a hypothesis to explain the reaction. AcCO_2H first combines with PhCH:NPh , in a way similar to an aldol condensation, to form $\text{HO}_2\text{C.COCH}_2\text{CHPhNHPh}$, the latter then forming the corresponding lactam, viz., $\text{CO.CO.NPh.CHPh.CH}_2$ (*loc. cit.*). The

lactam should then be converted into $\text{HO}_2\text{CCH(OH)CH.CPhNHPh}$, which in turn with PhCH:NPh would undergo double cyclic aldol condensation, thus: $\text{PhCH:NPh} + \text{HO}_2\text{CCH(OH)CH.CPhNHPh} \rightarrow \text{PhN:CPhCH[CH(OH)CO}_2\text{H]CHPhNHPh} \rightarrow$
 $\text{C}_6\text{H}_4 \begin{matrix} \text{CH(CO}_2\text{H)} \\ \diagup \quad \diagdown \\ \text{N} : \text{CPh} \end{matrix} \text{CHCHPhNHPh}$. The latter is unstable and decomp. to $\text{PhCH}_2\text{-NHPh}$ and $\text{C}_6\text{H}_4\text{C(CO}_2\text{H).CH.CPh:N}$. C. C. DAVIS

Atophan derivatives. II. Reduction of 2-anisyl- and 2-phenylquinolines. T. KAKU. Keijo Imp. Univ., Seoul, Korea. *J. Pharm. Soc. Japan* 48, 693-702(1928).—The derivs. of 2-anisyl- or 2-phenyl-quinoline previously obtained by K. (C. A. 21, 3622) were reduced by (a) Sn and HCl, (b) PtO_2 or Pt black and H_2 and (c) Na and EtOH. The 1st method gave only a small yield of tetrahydro compds. and the 2nd method gave only 60-70% in 20 hrs., whereas the 3rd method gave the reduction products almost quant. The statement of Bamberger (*Ber.* 23, 1142) and Yamaguchi (C. A. 21, 2696) that the reduction of quinoline compds. by Na and EtOH gives only py-tetrahydro compds. without reduction in the C_6H_4 ring has been confirmed. The reduction products obtained are colorless crystals or oils, insol. in H_2O , sol. in EtOH, Et_2O and other org. solvents. Their m. p. is about $25-6^\circ$ and their b. p. about $10-19^\circ$, lower than those of the unreduced mother substances. Their basicity is slightly stronger than that of the original compds. All salts of halogen acids m. above 200° (decompn). The following new compds. were prepd: 2-anisyl-py-tetrahydroquinoline, m. $68-9^\circ$, b_{18} $242-3^\circ$. HCl salt, m. $225-6^\circ$. HBr salt, m. $230-1^\circ$. HI salt, m. $210-1^\circ$. 6-Methyl-2-phenyl-py-tetrahydroquinoline, m. 44.5° , b_{17} 220° . HCl salt, m. $228-9^\circ$. HBr salt, m. 253° . HI salt, m. $254-5^\circ$. 6-Methyl-2-anisyl-py-tetrahydroquinoline, m. 85° , b_{18} 246.5° . HCl salt, m. 249° . HBr salt, m. $249-50^\circ$. HI salt, m. $239-40^\circ$. 7-Methyl-2-phenyl-py-tetrahydroquinoline, m. 57° , b_{18} $220-1^\circ$. HCl salt, m. 220° . HBr salt, m. 234° . HI salt, m. 217° . 7-Methyl-2-anisyl-py-tetrahydroquinoline, m. $87-8^\circ$, $b_{17.5}$ $246-7^\circ$. HCl salt, m. 216° . HBr salt m. $222-3^\circ$. HI salt, m. 205° . 8-Methyl-2-phenyl-py-tetrahydroquinoline, b_{18} 212° . HCl salt, m. $209-10^\circ$. HBr salt, m. $213-4^\circ$. HI salt, m. $229-30^\circ$. 8-Methyl-2-anisyl-py-tetrahydroquinoline, m. 55° , b_{18} 242.5° . HCl salt, m. 232° . HBr salt, m. 237° . HI salt, m. 226° . 6,8-Dimethyl-2-phenyl-py-tetrahydroquinoline, b_{17} 223° . HCl salt, m. 224° . HBr salt, $235-6^\circ$. HI salt, $235-6^\circ$. 6,8-Dimethyl-2-anisyl-py-tetrahydroquinoline, m. 59° , b_{10} 248° . HCl salt, m. $218-9^\circ$. HBr salt, m. 219° . HI salt, m. $219-20^\circ$. NAO UYEI

Alkaloids of Sinomenium and Cocculus. XXI. Constitution of trilobine and homotrilobine. H. KONDO AND M. TOMITA. Tokyo Imp. Univ. *J. Pharm. Soc. Japan* 48, 659-73(1928); cf. C. A. 19, 1708; 21, 2699. —Previously (C. A. 21, 2699) it was reported that trilobine (I) and 2 other bases were isolated from *Cocculus sarmentosus*. One of the latter has now been proved to be homotrilobine (II), $\text{C}_{20}\text{H}_{21}\text{NO}_2$ (m. 215° , $[\alpha]_D^{25}$ 314.8°). It contains one MeO group. In contrast to I, the HBr salt of II is more sol. in H_2O and Me_2CO . II and MeI gave the methylodide (III), m. $262-5^\circ$. Heating of III with

20% KOH-MeOH gave α -homotrilobinemethylmethine (IV), $C_{21}H_{23}NO_3$, (m. 115–7°, $[\alpha]_D^{25}$ 61.3°) and a small quantity of β -homotrilobinemethylmethine, m. 222°. IV and MeI gave α -homotrilobinemethylmethine-MeI (V), m. 264°, which on boiling with KOH-MeOH gave beside NMe_3 , a non-N compd. $C_{18}H_{13}O_2(OMe)$, m. 185°. II and Ac_2O gave, as a result of the rupture of the N-ring, a non-basic substance m. 285–7°. Heating of II with HBr in glacial AcOH in a closed tube resulted in the opening of the O-ring and gave a substance m. 270°. The above reactions show that contrary to the previous statement, II contains one N-Me group instead of a NMe_2 group and its structure can be expressed by $C_{18}H_{15}O(OMe)(NMe)(\geq O)$. It was previously suggested that 2 O atoms in I form either an ether linkage or a special ($-CO-$) group. The action of Ac_2O or $ClCOEt$ on I resulted only in the decompn. of the N-ring, but without any change in the groups contg. O atoms. The action of HBr in glacial AcOH on I, however, resulted in the rupture of the O-ring and gave a compd. contg. a newly formed OH group and a double bond originated as a result of the sepn. of another OH group in the form of H_2O . The compd. is named *desmethyltrilobinol* (VI), $C_{18}H_{17}NO_3$, m. 290°, $[\alpha]_D^{18}$ 229.3°. HBr salt decomp. 315°. With EtOH, VI forms an addn. compd. (VII) which loses EtOH on heating above 130°. It has no MeO group. The no. of OH groups as detd. by Zarevitinov's method on VII was 3, while VI contained only 2. VI and Ac_2O gave the *diacetyl deriv.*, m. 210°, $[\alpha]_D^{29}$ 302.1°. KOH fusion of VI gave 3,4-(HO) $_2$ C $_6$ H $_3$ CO $_2$ H and 1,2-(HO) $_2$ C $_6$ H $_4$. Oxidation of I with dil. $KMnO_4$ gave a glycol, $C_{19}H_{21}NO_3$, m. 265°. Further oxidation gave an intermediate dicarboxylic acid, decomp. 210–20°, and finally *des-N-trilobinedicarboxylic acid* (VIII), $C_{15}H_{15}O_7$, m. 288°. Action of HBr in glacial AcOH on VIII gave *desmethyl-des-N-trilobinedicarboxylic acid* (IX), $C_{17}H_{19}O_7$, m. 278.9° (decompn.). Heating of VIII with HI gave *desmethyl-des-N-trilobinedicarboxylic acid*, m. 267°, which with HBr in glacial AcOH gave also IX. The above reactions can be explained in a similar way as in the production of VI by the action of HBr on I. From the oxidation reactions and also from the fact that VIII gave a phthalim reaction, it is concluded that the position of double bond in I is like that of naphthamidine or acenaphthylene.

NAO UYEI

Chloroarsinosoquinine. III. FRANZ X. ERBEN. Rudolf-Spital Wien. *Ber.* 61B, 2106 8(1928); cf. *C. A.* 21, 1462.—In the earlier paper it was shown that the synthesis of chloroarsinosoquinine (I) from dehydroquinine and $AsCl_3$ requires 1 hr's. heating at 130.5°. At room temp., but after a much longer time (6 months in the dark), there is also obtained a solid compd., *chloroarsinosodiquinine* (II), $ReCl CHAs CH'CR$ ($R = C_{15}H_{21}(O_2N_2)$); the thin sirupy reaction product is taken up

in hot H_2O , filtered from the small dark insol. residue, pptd. with NH_4OH , washed with much H_2O , repeatedly repptd. from very dil. HCl or H_2SO_4 , dried and freed from unchanged dehydroquinine by extr. with $CHCl_3$. The II, unlike I, is sol. in hot $PhNO_2$. It begins to turn brown 170°, m. 202° (cor.), is sol. in MeOH, EtOH, C_6H_5N , aniline oil, CS_2 (unlike I), difficultly in Me_2CO and $CHCl_3$, almost insol. in $AcOEt$, insol. in EtO , C_6H_6 , PhMe and xylene. The pure preps. of I described in the earlier paper are unchanged in As content and m. p. by treatment with $PhNO_2$; a small dark impurity can be removed by prepg. the *mono-sulfate* (As 15.14, Cl 6.60%) which is sol. in H_2O while the impurity is insol.; with Na_2SO_3 the sulfate gives a thick white ppt. of the *mono sulfite* (As 15.32%).

C. A. R.

Glucoside of Aucuba japonica Thunb. T. KARIYONE AND K. KONDO. *J. Pharm. Soc. Japan* 48, 679–84(1928).—*Aucubin* (I), a glucoside, was obtained from the fruits of *Aucuba japonica* in 1.7% yield. Analysis gave as its compn. $C_{16}H_{24}O_9$. It m. 181°, b $_p$ 167.7°. Hydrolysis of I with emulsin or dil. acid gave a black ppt. which could not be purified. On reduction with H_2 and colloidal Pt, I absorbed 4 mols. H_2 and gave 1 mol. glucose and an aromatic oil, *tetrahydrodesoxyaucubigenin*, $C_9H_{16}O_2$, b $_p$ 154–60°, d $_4^{20}$ 0.942, $[\alpha]_D^{26}$ –4.5°, n_D^{24} 1.48524. The reaction can be expressed by $C_9H_{16}O_2 \cdot O \cdot C_7H_{12}O_6 + 4H_2 \rightarrow C_9H_{12}O_5 + C_7H_{12}O_6 + H_2O$. Reduction of I with H_2 and PtO at 1.5 atm. pressure gave a sirupy substance after absorption of 3 mols. H_2 . It is probably hydroaucubin.

NAO UYEI

Catalytic reduction of glucosides. T. KARIYONE AND K. KONDO. *J. Pharm. Soc. Japan* 48, 684–6(1928).—Since catalytic reduction of *aucubin* (I) gave a mol. of glucose and an already reduced aglycone (cf. preceding abstr.) the reaction was studied on a few other glucosides. Reduction of *salicin* (II) with H_2 and colloidal Pt gave a *crystal glucoside* (III), 1,2-MeC $_6$ H $_4$ OC $_6$ H $_4$ O $_6$, m. 164°, $[\alpha]_D^{31}$ –61.75°. III and emulsin or dil. acid gave 1,2-MeC $_6$ H $_4$ OH and glucose. Therefore the reduction of II, unlike

that of I, gives the product, reduced only on the OH group. The reduction of *arbutin*, however, is like that of I, and gave, after absorption of 4 mols. H_2 , hexahydrophenol and glucose.

NAO UYEH

Glucosides of digitalis leaves. A. WINDAUS. *Univ. Göttingen. Arch. expt. Path. Pharmacol.* 135, 253-8(1928).—In the active glucosides the genins are found in combination with different sugars, and they seem to be very closely related; thus, with the addn. of water digitoxin yields digitoxigenin and digitoxose, gitoxin yields gitoxigenin and digitoxose, digitalinum verum yields gitoxigenin, glucose and digitalose, oleandrin yields gitoxigenin and probably digitalose, gitalin yields gitoxigenin hydrate and digitoxose, cymarine yields strophanthidin and cymarose, and k-strophanthin yields strophanthidin, glucose and cymarose. All of the well-known aglycones of the active glucosides are hydroxylactones, which contain in their C framework a complex of 4 hydrated rings. In structure they approximate the sterols and the bile acids and possibly they are genetically connected with the sterols. The aglycones of the scilla glucosides appear to be of another type.

G. H. S.

Complex compounds of bivalent silver. Relation between ring closure and "specific affinity" (HIEBER, MÜHLBAUER) 6. Preparation and constitution of hydrargyrum salicylicum (RUPP) 17. The electrochemical reduction of azo dyes (HUBBUCH, LOWY) 4. The absorption spectra and constitution of diazotates (CAMBI, SZEGÖ) 3. The absorption spectra and constitution of azoxy compounds (SZEGÖ) 3. Spectrochemistry of rufin and its derivatives (DHÉRE, *et al.*) 11I. Oxidation of phenanthrene by bacteria (TAUSSON) 11C. Relation between dipole moment and constitution (ERRERA) 2. The electrical symmetry of the molecular structure of methane derivatives (EBERT, *et al.*) 2.

Unsaturated aliphatic hydrocarbons. I. G. FARBENIND. A.-G. Fr. 637,410, July 11, 1927. Unsaturated aliphatic hydrocarbons are prepd. by treating hydrocarbons or mixts. of hydrocarbons boiling at low or medium temps. with substances having large surface development such as active C or SiO_2 . The hydrogenation products of coal, mineral oils, etc., or components thereof are particularly suitable. In an example pentane is passed over active C at a temp. of 450-500°, amylene being the chief product. The products may be polymerized to produce rubber, or be combined with other elements such as halogens. Cf. C. A. 22, 1364.

Organic acid anhydrides. FRITZ DOERINCKEL and MARTIN SCHLIEPMANN (to I. G. FARBENIND. A.-G.). U. S. 1,691,647, Nov. 13. A mixt. comprising an org. acid salt such as NaOAc, a free org. acid such as glacial HOAc, and a chloride of Si, Ti or Sn is caused to react (suitably at room temp.) with $SiCl_4$ and the anhydride produced is sepd.

Gels produced from water-soluble salts of organic acids. EUGENE E. AYRES, JR., and ERLING H. HAABESTAD (to B. A. S. Co.). U. S. 1,691,424, Nov. 13. A stable colloidal gel is formed of AmCl and common soap or from similar materials among which are mentioned chlorides, mercaptans and nitrates of hydrocarbons generally and sulfonated fatty acids of high mol. wt., e. g., $EtNO_3$ with ethyl benzenesulfonate or ethyl nitrate and Mg abietate. U. S. 1,691,425 relates to production of esters by heating a gel produced in a similar manner from a liquid halide deriv. of a hydrocarbon such as AmCl or C_2H_5Cl and Na stearate or "common soap." A temp. of about 150° may be used for decomp. the gel and producing the ester. U. S. 1,691,426 related to the hydrolysis of AmCl or substance of similar reactivity, suitably by heating with soap or soap-forming substances at 150° followed by further heating with aq. alkali. A substance such as Am oleate may be added as a catalyst.

Aliphatic acids. W. J. HALE and W. S. HALDEMAN. Brit. 287,064, March 12, 1927. Formic, acetic, propionic, butyric and other aliphatic acids are produced from the corresponding primary alcs. b. below 350° by treating the vapor (which may be dild. with N_2 , H_2O vapor or air) with a reduced metal to effect dehydrogenation and immediately after with the unreduced metal oxide to oxidize the aldehyde to acid. Cu, Ag, Au and Hg are mentioned as suitable catalysts. Various details are given.

Aminoarylarsonic acids. ÉTABLISSEMENTS POULENC FRÈRES and CARL ORCHSLIN. Fr. 637,159, Nov. 22, 1926. Nitroarylarsonic acids are reduced by Zn in alk. soln. In examples, *p*-hydroxy-*m*-nitrobenzenearsonic acid and *p*-amino-*m*-nitrobenzenearsonic acid are reduced.

Anthraquinonesulfonic acids. JOHN THOMAS (to Scottish Dyes, Ltd.). U. S. 1,691,679, Nov. 13. Anthraquinone 100 is sulfonated with about 210 parts oleum contg. 40% free SO_3 and the strength of the acid is brought down to about 80% by

adding about 500 parts of concd. H_2SO_4 of 94–98% strength and about 90 parts H_2O ; the α -disulfonic acids which crystallize are filtered out and there is added to the filtrates a Hg compd. such as about 3.5% of Hg_2SO_4 and the material is heated at about 180° for about 10 hrs. to obtain β -monosulfonic acid. Cf. C. A. 22, 2572.

Oxidation of alkylaryldithiocarbamic acids. SILESIA VEREIN¹ CHEMISCHER FABRIKEN. Fr. 637,694, July 18, 1927. Alkylaryldithiocarbamic acids are oxidized to the corresponding disulfides by means of oxides of N and air in an alk. soln. In an example an alkali metal salt of methylphenyldithiocarbamic acid in an aq. soln. of Na_2CO_3 is oxidized to dimethyldiphenylthiuram disulfide.

Sulfuric esters of aliphatic acids. FARB- & GERBSTOFF-WERKE C. FLESCHE (to H. Flesch). Brit. 287,076, March 14, 1927. Sulfuric esters of dihydroxy-, trihydroxy- and poly-hydroxy fatty acids are produced from hydroxy fatty acids by introducing a fine spray or mist of H_2SO_4 contg. 5–10% of SO_2 into the cooled and actively agitated hydroxy fatty acids. Ricinoleic acid is converted into sulfodihydroxystearic acid, and dihydroxy stearic acids may be converted into their sulfuric esters without the use of solvents. The sativic acid prepd. from linoleic acid by use of permanganate may be similarly esterified.

Esters of cholesterol with unsaturated acids. WALTER MINNICH (to Soc. anon. pour l'ind. chim. à Bâle. U. S. 1,690,647, Nov. 6. Esters suitable for use as *therapeutic agents* are formed by the combination of cholesterol with phenylpropionic acid chloride or other unsatd. acids of the general formula $\text{R}-\text{COOH}$, in which R represents an aliphatic or aliphatic-aromatic hydrocarbon radical contg. at least one treble linkage. Cf. C. A. 22, 3668.

Catalytic production of esters, etc., from alcohols. F. C. ZEISBERG (to E. I. duPont de Nemours & Co.). Brit. 287,846, March 26, 1927. Vapors of EtOH or of a higher primary alc. are passed over a heated dehydrogenating catalyst under pressure to obtain an ester of the acid corresponding to the alc. used together with an alc. with twice the number of C atoms present in the starting material and a diminished production of acid and aldehyde. As catalyst there may be used Cu reduced in the presence of small quantities of Mn and Mg oxides, or Ni, Co or Fe in admixt. with other oxides such as those of Cr or Ca or oxides such as those of Zn, Mg, Cr or Mn or their mixts. and, in treating EtOH, a pressure of 270 atm. and a temp. of about 350° is suitable for conversion of about half the alc. to a mixt. of EtOAc, BuOH and AcH.

Halogenated alcohols. I. G. FARBENIND. A.-G. AND J. CALLSEN. Brit. 286,797, Dec. 13, 1926. The primary alc. employed as solvent in the process described in Brit. 284,000 (C. A. 20, 917) is replaced by a secondary alc., e. g., a soln. of bromal in isopropyl alc. heated with Al ethylate while II is continuously passed through the materials; after distg. off the alc. and acidifying, tribromoethyl alc. seps. Chloral may be similarly treated, and the use of H is not absolutely necessary.

Alkylation of aromatic compounds. A. VERLEY. Brit. 288,122, March 31, 1927. In effecting alkylations such as that of toluene to obtain *p*-cymene or of benzoic acid to obtain *m*-toluic acid, a mixt. of an alc., H_2SO_4 and an alkali metal pyrosulfate is used.

Acyl and alkyl phenols. W. J. POPE. Brit. 287,967, Dec. 31, 1926. Derivs. of resorcinol and hydroquinone such as the monopropionate, monoisobutyrate, monocaprate or monolaurate are heated with condensing agents such as ZnCl_2 , AlCl_3 , FeCl_3 , SnCl_4 , H_2SO_4 or H_3PO_4 to obtain other derivs. such as propionylhydroquinone, isobutyryl resorcinol, laurylresorcinol or stearylresorcinol, and the corresponding alkyl hydroquinones and resorcinols may be obtained by reduction of these products with Zn amalgam and HCl.

Sulfurized derivatives of naphthols. EMIL KRAUS (to Fabrik van chemische Producten). U. S. 1,690,641, Nov. 6. A mixt. formed of a naphtholic compd. such as β -naphthol together with S and an alkali is heated to the b. p. in an aq. medium and the resulting sulfurized derivs. are treated with a lower aliphatic aldehyde and a sol. sulfite, e. g. with CH_3O and Na_2SO_3 to obtain a product which may be used in *tanning*.

Chloroperylenes. F. BENSA. Brit. 288,171, April 2, 1927. Hepta- to dodecachloroperylenes are made by passing dry Cl through a soln. or suspension of perylene or a low-chlorinated perylene contg. a metallic chloride such as AlCl_3 or SbCl_5 . The degree of chlorination effected depends on the temp. and quantity of Cl used. Several examples are given.

Aminoanthraquinones. HERMANN BERTHOLD (to Grasselli Dyestuff Corp.). U. S. 1,691,428, Nov. 13. In forming compds. such as 1-amino-5-nitroanthraquinone an α -nitroanthraquinone such as 1,5-dinitroanthraquinone is treated with a hydrogenated base of the quinoline series such as 1,2,3,4-tetrahydro-2-methylquinoline in the presence of 2-methylquinoline.

Benzodiazines. I. G. FARBENIND. A.-G. Brit. 288,159, March 31, 1927. Benzodiazines are prepd. by condensing a homolog, analog or substitution product of a 2,4-dihaloquinazoline with 2 similar or dissimilar mols. of a compd. which contains a reactive H atom attached to a N, O or S atom. H halide is eliminated and residues of the amino or other compd. used replace the halogens in the quinazoline nucleus. The products may be used as *intermediates for making dyes and pharmaceutical compds.* Several examples are given.

Dichlorotoluidines. I. G. FARBENIND. A.-G. Brit. 287,110, March 15, 1927. 1-Methyl-2,5-dichloro-4-aminobenzene is made by nitrating 1-methyl-2-amino-5-chlorobenzene in H_2SO_4 , diazotizing the amino group, replacing it by Cl by use of Cu_2Cl_2 and reducing the nitro group.

Tetrazoles. A. BOEHRINGER. Brit. 287,924, March 30, 1927. Tetrazoles are prepd. by the action of hydrazoic acid or azides on amido- or imido-chlorides such as those produced by the action of org. or inorg. acid chlorides on mono-substituted acid amides or those presumably obtained as intermediate products in the treatment of oximes with acid chlorides. Examples are given of the production of α,β -cyclopentamethylene-tetrazole, and diphenyltetrazole; the acid amides obtained as by-products in the process described in Brit. 280,529 (C. A. 22, 3170) may be utilized for the production of tetrazoles. Cf. C. A. 22, 4538.

Tertiary nitriles. MAX BOCKMÜHL and GUSTAV EHRHART (to Winthrop Chemical Co.). U. S. 1,690,325, Nov. 6. A secondary nitrile of the general formula $R_2-CH-CN$, in which R stands for an alkyl residuc, such as diethylacetonitrile is treated with an alkali metal and the resulting compd. is then treated with allyl bromide or other alkylating agent.

Di- ω -haloacyldiphenyl ethers. SCHERING-KAHLBAUM A.-G. (formerly Chemische Fabrik auf Actien, vorm. E. Schering). Brit. 286,688, March 9, 1927. Diphenyl ether or a deriv. is treated with a halogenated acyl halide. Examples are given of the production of dichloroacetyl- or dibromoacetyl-diphenyl ether, dichloroacetyl-*o*-methoxydiphenyl ether and dichloroacetyl-*p*-hydroxydiphenyl ether.

Quaternary ammonium compounds. I. G. FARBENIND. A.-G. Brit. 286,984, Dec. 10, 1926. Quaternary NH_4 compds. are obtained by the action of sulfuric or aryl-sulfonic alkyl esters on halogen-substituted tertiary amines of the benzene or naphthalene series (suitably in a solvent such as toluene or $PhCl$). Examples are given of the treatment of 3-chloro-4-dimethylaminotoluene with *p*-toluenesulfonic methyl ester, 1-chloro-2-dimethylaminonaphthalene with Me_2SO_4 , *o*-chlorodimethylaniline with Me_2SO_4 , and 3,3'-dichloro(or dibromo)-4,4'-tetramethyldiaminodiphenylmethane with Me_2SO_4 or Et_2SO_4 .

Benzodiazine condensation products. I. G. FARBENIND. A.-G. Brit. 287,179, March 18, 1927. Quinazoline or a homolog, analog or substitution product, which is halogen-substituted in the diazine ring, is condensed with one or more org. components so that the halogen or halogens are replaced by 1 or 2 direct C-to-C linkages. The process is particularly applicable to the treatment of 2,4-dihaloquinazolines, and products thus obtained may be used as intermediates in the manuf. of *dyes and of pharmaceutical compds.* Several examples are given.

Benzanthrone derivatives. I. G. FARBENIND. A.-G. Fr. 638,710, Aug. 1, 1927. Amino and sulfurized derivs. of benzanthrone are prepd. by the action of NH_4OH in H_2SO_4 on benzanthranyl sulfides, disulfides, mercaptans or other derivs., adding, if necessary, a metallic compd. such as a sulfate of Fe or Cu to accelerate the reaction. In this way a monoaminobenzanthranyl disulfide is prepd. from benzanthranyl disulfide. Diamino compds. are obtained under more energetic conditions.

Thiomorpholines of the anthraquinone series. I. G. FARBENIND. A.-G. (Georg Kränzlein and Martin Corell, inventors). Ger. 466,894, Dec. 30, 1925. See Brit. 263,843 (C. A. 22, 170).

Pyridine derivatives. SCHERING-KAHLBAUM A.-G. Brit. 288,133, March 31, 1927. Halogenated 2-pyridone and its derivs. are prepd. by direct halogenation of 2-pyridone and its derivs. in the presence of a solvent such as $CHCl_3$ or dil. HCl . Examples are given, using Cl and ICl as halogenating agents to form a mixt. of 2-hydroxy-5-chloro- and 2-hydroxy-3,5-dichloropyridine, and 2-hydroxy-3,5-diiodopyridine, resp., from 2-pyridone. Cf. C. A. 22, 4131.

Acetic acid. J. KARPATI and M. G. HUBSCH. Brit. 287,135, March 16, 1927. C_2H_2 and O are passed into glacial $HOAc$ contg. a Hg salt such as the sulfate and cellulose fibers or other vegetable fibrous materials such as sawdust, straw or shavings which have been heated in a stream of N and activated with high-pressure steam. Preferably such a quantity of dil. $HOAc$ is added as to supply just sufficient H_2O for the hydration

of the C_2H_2 . A temp. of 35–40° is suitable, and the C_2H_2 and O may be supplied together or alternately.

Acetic and other acids. HENRY DREYFUS. Fr. 637,763, July 16, 1927. AcOH is obtained free or as the Me ester by heating MeOH with CO in the presence of an inorg. acid or an inorg. acid contg. an org. group, *e. g.*, a sulfonic acid or its salt. Me_2O or Me formate or acetate may replace MeOH. A pressure up to 300 atm. may be used and the temp. is preferably 300–400°. The phosphoric acids or mixts. of them are particularly useful as catalysts; boric, arsenic and phosphomolybdic acids and acid Al phosphate may also be used. The MeOH may be produced from mixts. of CO and H₂. The presence of water favors the production of free AcOH, while excess MeOH gives MeOAc. Acetone may be produced by leading the AcOH directly over MnO at 400–500°. The process may be extended to higher alcs., *e. g.*, EtOH, or their ethers or derivs. to produce PrOH, etc., or their esters. Cf. C. A. 22, 1365.

Concentration of acetic and formic acids. SOCIÉTÉ JAMES NELSON, LIMITED. Fr. 637,389, July 9, 1927. AcOH and HCOOH are concd. by adding to the aq. soln. a sol. acetate or formate, preferably the Na or K salt, and distg. under reduced pressure first at a low temp. till all the water is removed, and then at a higher temp.

Benzoic acid. MONSANTO CHEMICAL WORKS. Fr. 638,763, Aug. 2, 1927. A mixt. of phthalic anhydride vapor and steam is passed over a catalyst such as ZnO at a temp. between 200° and 600°.

2-Aminonaphthalene-3-carboxylic acid. ERNST HOTZ and VALENTIN LANZ (to Grasselli Dyestuff Corp.). U. S. 1,690,785, Nov. 6. 2-Aminonaphthalene-3-carboxylic acid is obtained in about 90% theoretical yield from 2-hydroxynaphthalene-3-carboxylic acid and NH_3 by subjecting the products of reaction to the action of a bivalent Fe compd. (which may, *e. g.*, be added as $FeCl_2$ or $FeSO_4$ or directly as $Fe(OH)_2$) and thereafter decompg. the complex Fe compd. which is formed and liberating the free 2-aminonaphthalene-3-carboxylic acid (suitably by the action of HCl). Compds. of Co and Ni may be used similarly to those of Fe, but compds. of Zn, Ca, Mg and Cu produce no corresponding salts similar to that of Fe. Numerous details are given.

Citric acid. DISTILLERS CO., LTD. and A. M. PRAKE. Brit. 287,604, Nov. 27, 1926. Citric acid is obtained by treatment of pectinous materials such as fruit pulp mixts. with enzymes naturally present in citrous fruits; catalysts such as Mn or Ti salts may be added.

6-Aminoacenaphthene-5-carboxylic acid. I. G. FARBENIND. A.-G. Fr. 637,406, July 11, 1927. 6-Aminoacenaphthene-5-carboxylic acid is prepd. by treating 5-acetylacenaphthene or 5-chloroacetylacenaphthene by an alk. hypochlorite soln., nitrating the 5-acenaphthenecarboxylic acid obtained, and reducing the 6-nitro-5-acenaphthene-carboxylic acid.

Naphthalene-1,4,5,8-tetracarboxylic acid. I. G. FARBENIND. A.-G. Fr. 637,212, July 7, 1927. See Brit. 274,103 (C. A. 22, 1981).

Dehydrating alcohol by distillation with added substances. U. S. INDUSTRIAL ALCOHOL CO. Brit. 287,607, Nov. 29, 1926. A substance such as C_6H_6 is added, forming a ternary azeotropic mixt. which on condensation seps. into 2 layers; the process is applicable to sepn. of alcs. such as MeOH, PrOH or BuOH, esters such as MeOAc or EtOAc or Me or Et propionates, aldehydes such as AcH or ketones such as acetone, Me Et ketone or di-Et ketone from admixture with water. Among other liquids which may be added to effect similar sepns. are: CCl_4 , ethylene dichloride, EtCl or EtBr and slightly sol. esters. An app. is described. Cf. C. A. 22, 4200.

Crotonaldehyde and its homologs. SOCIÉTÉ ANON. DES DISTILLERIES DES DEUX SEVRES. Fr. 637,517, July 12, 1927. See Brit. 274,488 (C. A. 22, 2171).

Ethylene glycol. BRITISH DYE STUFFS CORP., LTD., K. H. SAUNDERS and H. WIGNALL. Brit. 286,850, Feb. 8, 1927. Ethylene chlorohydrin is carried off by a current of steam, from a crude soln., and continuously hydrolyzed in vapor phase, *e. g.*, in a tower to the top of which there is continuously supplied a soln. of Na_2CO_3 or a strong soln. of NaOH for the production of glycol or ethylene oxide, resp. An app. is described.

Cinchophen. RICHARD PASTERNAK (to Charles Pfizer & Co.). U. S. 1,690,128, Nov. 6. Substantially mol. proportions of aniline, 30% aq. soln. of pyruvic acid, and benzaldehyde are added to boiling alc. at about 100°.

Hexamethylenetetramine. SCHIEFERWERKE AUSDAUER A.-G. Brit. 286,730. March 10, 1927. Formalin is permitted slowly to run into a soln. of NH_4Cl which is supersatd. with $NaHCO_3$ or into a soln. of NaCl and NH_4HCO_3 . The mixt. obtained can be used in the artificial resin industry, or the $(CH_2)_6N_4$ can be sepd. by extn. with alc.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

The Donnan theory of "membrane equilibrium." K. SHIGI. *Acta Schol. Med. Univ. Imp. Kioto* 9, 511-42(1927).—Studies of Donnan equil. were made on various pathol. human serums. They could be divided into three main classes. These classes exhibited characteristic properties of the Donnan equil. and might be due to a characteristic change of the protein. The Donnan equil. was noticed to exist when the concn. of a neutral salt added to a human serum did not exceed a certain limit. Isolated protein did not exhibit this characteristic but did form an electrolyte with an acid or base and then exhibited the Donnan equil. When a neutral salt is present in addn. to an acid or base the equil. is retarded but the final e. m. f. is attained as when a neutral salt is present. Isolated proteins when heated above 60° or exposed to ultra-violet ray for 15-16 hrs. are incapable of forming electrolytes with an acid or base. JOHN T. WOLF

Emanations of ultra-violet rays from some organic phosphatides after their irradiation. CESARE SERONO AND ALFONSO CRUTO. *Istituto Sersono, Roma. Gazz. chim. ital.* 58, 402-4(1928).—See C. A. 22, 4361. C. C. DAVIS

The effects of x-rays on the adrenal glands. N. F. FISHER, E. LARSON AND A. BACHEM. *Univ. of Ill. Endocrinology* 12, 335-41(1928).—Adrenal deficiency was produced in dogs by radiation of the left adrenal after right adrenalectomy with 3 to 5 erythema doses. The histological changes were in proportion to the no. of doses administered. No change in blood cholesterol occurred in the adrenal deficiency.

H. J. DEUEL, JR.

The biocatalyst content of normal and pathological tissues. HANS V. EULER AND HUGO JOHANSSON. *Univ. Stockholm. Z. physiol. Chem.* 178, 209-16(1928).—Human placenta contains considerable cozymase, since an ext. prepd. therefrom activates the fermentation of glucose by washed dried yeast and decolorizes methylene blue. The cozymase content is less than that of kidney and liver of smaller mammals, and it evidently does not constitute a reserve substance for the embryo but belongs rather to an active enzyme system. The fact that zymophosphate serves here as an excellent H-donor in the methylene blue reduction indicates that mutase is also present. This activation by zymophosphate is much greater with placenta than with muscle. Direct respiration of the tissue, however, as measured by O consumption, is diminished by addn. of cozymase + zymophosphate. Biocatalyst Z, which activates fresh yeast fermentation, is present in practically all organs, but to a less extent in cancerous than in normal liver.

A. W. DOX

The structure of silk fibroin. EMIL ABDERHALDEN AND HERBERT MAHN. *Univ. Halle. Z. physiol. Chem.* 178, 253-75(1928).—If fibroin is a mixt. of 2 substances, one cryst. and the other amorphous, as indicated by Herzog's Röntgen diagrams, it should be possible to effect a sepn. into 2 fractions after treatment with certain reagents which do not bring about too deep-seated changes. When a CHCl₃ soln. of Br was added to fibroin dispersed in 50% LiBr, a flocculent ppt. was formed leaving a part of the proteinoid still in the dispersed form. The yield (75-80%) and the analysis of the ppt. were quite const. Hydrolysis of the ppt. yielded glycine, alanine, serine and 2,5-dibromotyrosine. The sol. portion after the Br treatment yielded glycine, and alanine and serine were also probably present, but the identification of other amino acids was extremely difficult on account of the LiBr which could not be completely removed. The small amt. of sol. residue may perhaps be due to impurities of silk glue adhering to the fibroin. The results afford no confirmation of Herzog's view that fibroin is a mixt., but point rather to the homogeneity of fibroin. If N alkali is added to the LiBr dispersion of fibroin, the amt. of ppt. obtained by addn. of Br decreases with the duration of the alkali treatment, until a min. is reached after which no noteworthy change occurs. If the dispersion contg. alkali is heated for a short time on the water bath, the amt. of Br ppt. is practically the same as with the untreated dispersion. Alkali treatment at 37° gives an increase in amino N which is greater than with elastin or gelatin, and a decrease in rotation. The amt. of diffusible products also increases. On the other hand, a brief alkali treatment renders the fibroin less and a prolonged treatment more amenable to hydrolysis by a mixt. of trypsin-kinase and erepsin. Dispersion in 50% LiBr is evidently not a purely phys. phenomenon but probably involves mol. changes of a cleavage nature. The fact that the fibroin dispersion is attacked by pancreatic

enzymes does not exclude the possibility that this proteinoid is composed largely of 2,5-diketopiperazines or related structures, but points rather to the simultaneous presence of polypeptide linkages. Attempts to benzoylate the partially hydrolyzed mixt. obtained by treating the dispersed fibroin with *N* alkali 71 hrs. at 38° were unsuccessful, although 70% of the total N was present as amino N. Most of the BzCl was recovered as BzOH.

A. W. DOX

The geo-chemistry of life.* E. HERLINGER. *Z. angew. Chem.* 41, 812-5(1928).—A discussion of the origin and spread of life processes as related to the division and distribution of the chem. elements and ions of the earth's crust.

C. R. F.

The behavior of casein in partial solution in calcium hydroxide. VLADIMIR PERTZOFF. Harvard Medical School. *J. Biol. Chem.* 79, 799-813(1928).—The soly. and amt. of base in soln. in the system casein-Ca(OH)₂-H₂O depend upon the amt. of Ca(OH)₂ added and the casein concn. The exptl. results were described by the relation

$$S = \frac{K_2}{(1/Ca(OH)_2) - [(K_1 - K_2)/C]}$$
 where *S* is the amt. of casein dissolved, Ca(OH)₂ the base added, *C* the total amt. of casein in the system, and *K*₁ and *K*₂ are consts. whose values in terms of g. of casein per equiv. of base are 2180 and 545, resp. The relation between *S* and the amt. of Ca(OH)₂ bound by it, Ca(OH)₂_S, is expressed by $S = K_2/[Ca(OH)_2]_S$, where *K*₂ = 1440. The consts. of the above equations and the behavior of casein toward Ca(OH)₂ are interpreted in terms of known physicochem. consts. NaOH at 5° behaves toward casein like Ca(OH)₂ at 25° and the same equations are applicable.

ARTHUR GROLLMAN

The presence in peptone of a blood anticoagulant. BOTHO E. BRÜDA. Univ. in Graz. *Klin. Wochschr.* 7, 1742(1928).—By a process identical with that employed by Howell for the prepn. of heparin, it is possible to obtain from Witte peptone a substance that is similar to, if not identical with, heparin, both pharmacologically and chemically. The possible identity of the two products becomes more probable in view of the fact that heparin is not a specific liver substance but can be obtained from other body tissues.

MILTON HANKE

The separation of the citric acid dehydrase from liver and of the lactic acid dehydrase from yeast. FREDERICK BERNHEIM. Biochem. Lab., Cambridge. *Biochem. J.* 22, 1178-92(1928).—An enzyme has been sepd. from liver which will reduce methylene blue in the presence of sodium citrate but will not take up oxygen in a Barcroft app. This is also true of the lactic acid dehydrase sepd. from yeast. The product which citric acid yields has not been identified, but in the case of the lactic acid enzyme, pyruvic acid is formed. The specificity of the enzymes is upheld, since their sepn. depends on differences in the physical properties of the enzymes.

BENJAMIN HARROW

The duration of the effect of ultra-violet radiation on chickens. WALTER C. RUSSELL, O. N. MASSENGALE AND C. H. HOWARD. N. J. Agr. Expt. Station. *J. Biol. Chem.* 80, 155-62(1928).—The % bone ash, and the Ca and inorg. P of the blood were selected as criteria to measure the duration of the effect of ultra-violet radiation from a quartz mercury lamp. As measured by the bone ash % the effect on bone formation of a single exposure of 45 min. to the filtered radiation (equiv. to 15 min. of direct exposure) at a distance of 3 ft. lasted 1 week. The duration of the effect was 2 weeks for single exposures of 90, 180 and 270 min. The amts. of blood Ca and inorg. P vary directly with the length of exposure. The values of blood Ca and inorg. P fluctuate with the curve of the % of bone ash in such a manner as to suggest a relationship to the process of mineral deposition in the bones. The results suggest the possibility of the use of single exposures at intervals of several days rather than daily exposures in the practical applications of ultra-violet radiations.

A. P. LOTHROP

The isoelectric precipitation of pepsin. II. FREDERIC FENGER, ROBERT H. ANDREW AND A. WHEELER RALSTON. Armour and Co., Chicago. *J. Biol. Chem.* 80, 187-90(1928); cf. *C. A.* 21, 2706.—An ash-free pepsin with an isoelec. point of *p*_H 2.5 was obtained by repeated washing with HCl of *p*_H 2.5. It has the highest proteolytic activity reported by any investigator when assayed by an official method and it is believed that it represents the form of the enzyme naturally occurring in the glandular mucosa of the stomach. It has the following % compn.: C 53.15, H 7.2, N 14.43, S 0.88, P 0.13. Fractions pptd. at higher *p*_H values show progressively decreasing proteolytic activity and evidently represent early stages of peptic decompn. The decrease in activity is paralleled by loss of the complex protein characteristics of the enzyme pptd. at *p*_H 2.5.

A. P. LOTHROP

The influence of quinine salts on pancreatic lipase. ZUMMO CATALDO. *Boll. soc. ital. biol. sper.* 3, 455-9(1928).—The object of this study was to det. whether quinine

salts added to the pancreatic juice would modify its lipase activity, not only when tested against tributyrin, but also against higher glycerides, *e. g.*, triolein. To 6 cc. of pancreatic juice was added one cc. of a 5% soln. of quinine-HCl and the mixt. was allowed to stand at room temp. for 12 hrs. To one cc. of this mixt. was added 2 cc. of oil of almond. It was incubated for 1-3-6 hrs. and neutralized with 0.1 N NaOH. The results show that the addn. of quinine salts to pancreatic juice in some cases leads to the entire disappearance of its lipase activity; in the majority of cases the activity is only slightly affected; and in a few cases it is not changed at all. C. is unable to interpret these results.

PETER MASUCCI

Industrial biochemistry. II. Chemistry of the proteins. EDWIN R. THREIS. Lehigh Univ., Bethlehem, Pa. *J. Am. Leather Chem. Assoc.* 23, 526-51, *et seq.* (1928).—A review.

H. B. MERRILL

Female hormone in yeast. E. GLIMM AND F. WADEHN. Tech. Hochschule, Danzig-Langfuhr. *Biochem. Z.* 197, 442-4 (1928).—Killed yeast is extd. several times with boiling alc., then chloroform. The residues after evapn. are combined and purified. They are dissolved in dil. MeOH, which is then evapd. and the residue is emulsified in dil. MeOH. On shaking with ether most impurities remain in the ammoniacal soln. The ether soln. is colored yellow and leaves on evapn. a little residue which is partly sol. in H₂O. From 1 kg. beer yeast 1 g. oily residue was obtained, of which 25 mg. was sufficient to initiate rut in a mouse.

S. MORGULIS

The significance of the lipoids in cell permeability. N. OKUNEV. Acad. Sci., Leningrad. *Biochem. Z.* 198, 296-310 (1928).—Lecithin and cholesterol are definitely surface-tension-active substances accumulating in the water-benzene or water-olive oil interface when they are dissolved in the lipid solvent or emulsified in the water. Generally, their surface-tension-lowering ability was greater in the water-benzene system, and lecithin is more active than cholesterol. In a water-benzene interface lecithin still produces a marked lowering of surface tension in a concn. of 1:400000. In lipid solvents the surface-tension activity of both lecithin and cholesterol is generally greater than in water emulsion. When lipid in a lipid solvent and trypan blue in aq. soln. are both present in either of the above systems the effect on the interfacial tension is such as if only one was present, the one which in the given concn. is the more effective. It is believed that lecithin can regulate the permeability of the protoplasm surface through changes in concn.

S. MORGULIS

Conservation of the properties of almond emulsin. M. BRIDEL AND (MLLE.) M. DESMAREST. *Bull. soc. chim. biol.* 10, 1050-5 (1928).—A sample of acetonetic emulsin, 8 yrs. after its prepn., conserved intact its β -glucosidase properties; its lactase had lost $\frac{1}{2}$ of its activity and sucrase was practically absent. Thus by simple aging a product is obtained which is active on β -glucosides but free of sucrase. **Properties of an emulsin twenty-three years old.** *Ibid* 1056-60.—Samples of emulsin prepd. in 1905 possessed glucosidase and lactase with about 50% of their original activities but no sucrase.

L. W. RIGGS

Action of trypsin. Influence of the products of digestion on the process. YVONNE SCHAEFFER. *Compt. rend. soc. biol.* 99, 669 (1928); *cf. C. A.* 22, 4551.—The diln. of the products of tryptic digestion after attaining equil., by the addn. of water, involves an acceleration of the process. The concn. of the products of peptic digestion by the addn. of peptone and amino acids retards the process. **Influence of the concentration of the enzyme and of the substrate.** *Ibid* 670-1.—For the same quantity of substrate the activity of the enzyme diminishes rapidly at first, then more slowly while its concn. increases. For the same concn. of enzyme there is an optimal concn. of substrate in which the p_H is lowered 5.5 to 6.5% of its initial value.

L. W. RIGGS

Nature of pyocyanase. SEIGO HOSOYA. *Compt. rend. soc. biol.* 99, 771-3 (1928).—A lengthy procedure is described whereby it is believed that the active substance of pyocyanase is isolated in a state of chem. purity. This substance has hemolytic properties.

L. W. RIGGS

Absorption of glucose by normal erythrocytes. F. RATHERY, R. KOULSKY AND (MLLE) S. GIBERT. *Compt. rend. soc. biol.* 99, 683-5 (1928).—By the methods of Bertrand and of Baudoin for estg. glucose, it was found that washed erythrocytes did not absorb sugar from the plasma in any const. or regular way. Absorption of glucose from the plasma by unwashed erythrocytes was insignificant either for plasmatic or added glucose. With added glucose the percentage of sugar absorbed from the plasma by erythrocytes in 9 cases of washed erythrocytes ranged from 5 to 23%, with a possible error of 4%.

L. W. RIGGS

Influence of mineralization on the osmotic pressure of the albumin of the blood in vitro. P. GRABAR AND J. WEILL. *Compt. rend. soc. biol.* 99, 868 (1928); *cf. C. A.* 22,

2000.—By the addn. of 11 mg. of NaCl and 9 mg. of NaHCO₃ to 20 cc. of serum, the Cl content was increased from 3.75 to 4.03 g. per l., while the osmotic pressure fell from 27 to 21 cm. Other tests gave similar results.

L. W. RIGGS

Influence of the quartz lamp irradiation (Hanau system) on the cholesterol content of blood of man and animals. ST. MALCZYNSKI. *Compt. rend. sol. biol.* 99, 922-5 (1928).—Irradiation by the quartz lamp for periods of 10 min. was always followed by a temporary increase in the cholesterol of the blood. The reason for this action is unknown.

L. W. RIGGS

Chemical equilibria in diastatic systems. Theoretical discussion. ERNST SYM. *Compt. rend. soc. biol.* 99, 1011-3 (1928); cf. Dietz, C. A. 1, 2903. **Experimental results.** *Ibid* 1013-5.—The system used in these expts. was the same as that employed by Dietz, except for lipase prepd. by the method of Rosenheim. The results with lipase confirmed those obtained by Dietz. Four expts. are described from which it is concluded that in a diastase-catalyzer system the equil. is the result of 2 actions, and that it depends on the difference of the activities of these 2 agents. Lipase forms a sep. phase. There is a current of diffusion of butyric acid, alc. and ester between the lipase and the solvent contg. the catalyzer. The ester formed by the catalyzer is hydrolyzed by the diastase and inversely. The equil. attained is not dynamic; it is suddenly caused by the macro-heterogeneity of chem. reactions or by phases.

L. W. RIGGS

Oxidation of uric acid under the influence of acceptors of hydrogen. S. DOBROWLSKA. *Compt. rend. soc. biol.* 99, 1022-3 (1928); cf. Przylecki, C. A. 22, 245, 248, 439, 2178.—The object of this study was to det. the behavior of uric acid under the influence of acceptors of H, and particularly of substances contg. the S-S group, in the absence of diastase. Methylene blue was inactive toward uric acid with a p_H below 8.0, but with a p_H above 8.0, a temp. of 37° and a concn. of 1 in 5000, it degrades 50% of the uric acid in 6 days, CO₂ being evolved. The action of the S-S group was studied by means of thioglycolic acid which oxidizes uric acid on passing from S-S to S-H. Anaerobiosis retards strongly the oxidation of uric acid. The presence of 0.2 mg. Cu in 100 cc. of a mixt. of uric and thioglycolic acids accelerates the oxidation of uric acid to 65% in 24 hrs. and 85% in 48 hrs. The presence of methylene blue increases the action of thioglycolic acid. The addn. of KCN 1 to 1000 causes a pronounced diminution in the oxidation of uric acid. During the action of thioglycolic acid on uric acid CO₂ is formed. The resemblance of thioglycolic acid to glutathione suggests that the latter may take part in the uricolysis in the animal body.

L. W. RIGGS

Biochemistry and geochemistry of iodine. Etiology and prophylaxis of endemic goiter. G. LUNDE. *Northwest Med.* 27, 412, 479 (1928); *J. Am. Med. Assoc.* 91, 1467, 1662; cf. C. A. 22, 1370.—The I that is released from weathered rocks is carried by rivers to the sea, where it is absorbed by the plankton, like other nutritive salts from the land, especially P and Ca compds. The production of plankton is periodic and depends, on the Norwegian coast, chiefly on the supply of nutrients from the land. These nutrients are most plentiful during the melting of snow in the spring, when large quantities of I which have been released by the erosion of rocks are carried to the sea. During and immediately after the flowering of plankton in the upper layers of the ocean, only a small quantity of the plankton is utilized for food of marine animals. The great mass sinks to the bottom and is partly consumed by bottom fauna. The bottom fishes obtain their I mostly from these animals. On the decay of various plants and animals a part of the I is again set free and can be absorbed anew by plants; much however remains in bottom sediments. I is also set free at the surface into the atm. and is carried back by pptn. Sea air is much richer in I than inland air. Fish products and especially those of easily transportable canned goods have a high content of I in org. combination and offer a simple means of supplementing iodized salt prophylaxis.

L. W. RIGGS

Action of various enzymes on calcium and sodium glycerophosphates. ANGELO CECARDI AND PIA LATZER. *Rend. ist. lombardo sci.* 1927, 856.—Ca glycerophosphate in physiol. soln. (1:100) was added to samples of cobra, bee and wasp poisons. After 10 min. in the thermostat at 50° the solns. of cobra and bee poisons were limpid; that of the wasp poison was turbid. After 1 hr. the 3 solns. were turbid. The ppt. from the soln. of wasp poison, dissolved in cold dil. HNO₃, gave an immediate ppt. with NH₄ molybdate. The ppt. from the cobra and bee poisons remained limpid for 12 hrs. when treated as above. A filtrate with the wasp enzyme gave with HNO₃ and NH₄ molybdate a yellow ppt. of NH₄ phosphomolybdate; nothing results with that from cobra poison, even after 12 hrs. The first ppt. was caused by Ca glycerophosphate. Wasps' enzyme acted also on Na glycerophosphate with and without Ca salt.

R. SANSONE

Action of Hydrapid (octahydroanthracensulfonic acid) on glycerophosphate of calcium and sodium. ANGELO CONTARDI AND PIA LATZER. *Rend. ist. lombardo sci.* 1927, 858.—Ca or Na glycerophosphate soln. added to a 5% Hydrapid soln. and heated for some time at 100° seps. phosphoric acid. The phosphate soln. with cold dil. HNO₃ and NH₄ molybdate gives no ppt., even after 12 hrs.; the hydrated soln. gives a ppt. of NH₄ phosphomolybdate after a short time. R. SANSONE

Action of octahydroanthracensulfonic (Hydrapid) on lecithin and lysocithin. ANGELO CONTARDI AND PIA LATZER. *Rend. ist. lombardo* 1927, 858.—By adding to a 1% Cd lecithin soln. $\frac{1}{10}$ its wt. of Hydrapid as a 5% soln., and warming to 100°, the opalescent soln. becomes limpid, giving an abundant ppt. in 1–10 hrs. according to the amount of Hydrapid used. * The soln. agglutinates blood, and the ppt. is slightly hemolytic. The ppt. dissolved in EtOH and repptd. with excess, filtered and washed with EtOH, is strongly hemolytic (1:4000). It contains fatty acids, P and choline, and dissolves in alc., repptg. a double salt with a cold satd. CdCl₂ soln. If the reaction is not completed, and the catalyst acts for 12–20 hrs., the ppt. rises slowly to the surface of the soln. Total decompn. is sometimes difficult, the soln. and ppt. losing all hemolytic power. The soln. contains CdCl₂, H₃PO₄, and choline. The ppt. only contains fatty acids sol. in EtOH. The I no. is 70 with a partial decompn. and 38 with a total. R. SANSONE

Buffering as a biological principle. VICTOR BERMAN. *Z. angew. Chem.* 41, 153–7(1928); cf. *C. A.* 22, 2761.—B. emphasizes the importance of buffering in relation to biological, nutritional and agricultural problems. He mentions the advantage of proper buffering in yeast manuf. where insufficient buffering of the nutrition medium causes degeneration of the yeast cells, and in the beer industry, where malt is used with better results than unmalted barley which has lesser buffering action and thus causes degeneration of the yeast cells. Also in the nutrition of humans, the buffered foods seem to have qualities superior to non-buffered ones. Concerning the action of buffers in agriculture, B. points out that the non-buffered artificial fertilizers are very often unfit on the non-buffered mineral soils, while they may be used in any amt. on humus soils, which are rich in buffer substances. Manure, which is strongly buffered, is therefore to be preferred for mineral soils. G. SCHWOCH

The influence of pepsin and of trypsin-kinase on polypeptides containing *d*-glutamic acid (ABDERHALDEN, ROSSNER) 10. B—METHODS AND APPARATUS

STANLEY R. BENEDICT

A direct method for making total white blood counts on avian blood. DANIEL BLAIN. Vanderbilt Univ. *Proc. Soc. Exptl. Biol. Med.* 25, 594 6(1928).—A method for counting white blood cells by using neutral red staining soln. and formalin as dil. fluids was found to be accurate and applicable to avian blood in which the nuclei of the red blood cells are invariably present. C. V. B.

A body plethysmograph for the study of respiratory movements in human beings. CARL A. L. BINGER AND JOHN S. DAVIS, JR. Rockefeller Inst. *Proc. Soc. Exptl. Biol. Med.* 25, 607–10(1928).—An app. is described which was designed to eliminate errors in recording graphically the rate and depth of respiration. C. V. B.

Improved methods for the extraction of melanin from human urine. GRACE MEDES AND HILDING BERGLUND. University Hospital, Minneapolis. *Proc. Soc. Exptl. Biol. Med.* 25, 535–7(1928).—A method is described for extrn. of melanin from urine. Properties are listed for the melanin obtained. C. V. B.

A rubber-opposed hemodromograph used to measure reflux in aortic insufficiency. W. DOCK AND J. J. O'HARA. Stanford Univ. *Proc. Soc. Exptl. Biol. Med.* 25, 706–9(1928).—A simple instrument for use in studying reflux is described. C. V. B.

A modification of the Congo red method for the determination of pepsin. E. BEER AND O. PECZENIK. Univ. Wien. *Fermentforschung* 10, 88–90(1928).—Kawahara's Congo red method (*C. A.* 19, 838) is based on the fact that the dye adsorbed by albumin in dil. soln. does not undergo a color change in the presence of $\frac{1}{10}$ N HCl until the adsorption power is diminished by enzymic breakdown of the protein into simpler products. A change of color to blue or violet then indicates digestion. The reagent may be improved by staining a 1:1000 albumin soln. with "rose bengale B" (tetrachlorotetraiodo-

fluorescein) instead of Congo red and acidifying to 0.05 *N* by adding an equal vol. of 0.1 *N* HCl. Sep. portions of 3 cc. are then mixed with 1 cc. of 1:250, 500, 1000 and 2000 pepsin solns., and a boiled 1:250 soln. for control, and placed in a thermostat at 40°. The peptic activity may be expressed as the diln. of enzyme at which decolorization occurs in a given time, or the diminution in color intensity may be measured in a colorimeter. In 2-4 hrs. this reagent will detect peptic activity which would require 16 hrs. with the Congo red reagent.

A. W. DOX

The occurrence and identification of a hemochromogen-like pigment in animal suprarenals. A. ROSENBOHM. Cancer Inst., Hamburg-Eppendorf. *Z. physiol. Chem.* 178, 250 1(1928).—In a spectroscopic examn. of various animal organs the suprarenals of the pig showed uniformly 2 absorption bands, the location of which coincided with those of hemochromogen or reduced hematin. The same phenomenon was observed with the suprarenals of freshly killed steers and white rats. Apparently the hemochromogen occurs only in the medullary and not the cortical part of the gland. It was not found in other normal tissues. To det. whether any relationship exists between adrenaline and hematin formation, blood corpuscles were suspended in 1:2500 adrenaline solns. and kept 12 hrs. at 37°. Under these conditions neither hematin nor hemochromogen could be detected, but occasionally acid methemoglobin was found.

A. W. D.

The formation of hexone and purine bases in the development of the hen egg. JEN-ICHIRO SAGARA. Med. Acad., Nagasaki. *Z. physiol. Chem.* 178, 298-301 (1928).—Large quantities of chicken embryos (517-3327 g.) after 9, 14, 17 and 19 days' incubation were analyzed for purines and hexone bases. Purines were found but were not sepd. and identified. Of the hexone bases, arginine and lysine were isolated as picrates and histidine was isolated as picrolonate. With the exception of histidine the max. values were obtained on the 14th day, after which a slight decrease was noted. These values in % of embryo were: purines 0.0162, arginine 0.0149, histidine 0.0005 and lysine 0.1696. A storage of lysine is apparent.

A. W. DOX

Refractometric determination of fibrinogen. SIGISMUND SOMOGYI. Univ. Budapest. *Z. ges. expit. Med.* 53, 851-4 (1927).—The refractive index for 1% fibrinogen soln. = 0.00202. In Pulfrich units the factor is 0.187 (cf. *Arch. expit. Path. Pharmacol.* 94, 120). The method consists in detg. the *n* of blood in Ca citrate plasma and in Ca citrate serum, the difference being fibrinogen. The plasma is made up: 1 part Na citrate to 15 parts blood, and then 1 part CaCl₂ to 30 parts citrated plasma.

F. L. D.

A new syringe electrode for the direct measurement of *p*_H. C. H. LASCH. Univ. Potock. *Z. ges. expit. Med.* 56, 157-9 (1927).—The syringe is of the Luer type with a glass stopcock at the end instead of the ground tip, and a three-way stopcock fused to the barrel. The Pt electrode is attached to the tip of the plunger, the lead going through the plunger. Biological fluids can be collected easily and the *p*_H detd. without any exposure to the air. The side stopcock is for introducing H₂.

F. L. DUNN

Progress in the standardization of stains. Five years of stain standardization. H. J. CONN. N. Y. Agr. Expt. Sta., Geneva. *Stain Tech.* 3, 105-9 (1928).—Since the inception of the work of the Commission on Standardization of Biological Stains in 1923, 41 stains have been certified. Rose bengal was the only stain added to the list in 1928. The % rejects on stain samples submitted by manufs. for certification by yrs. is 1923, 45; 1924, 30; 1925, 13; 1926, 7; 1927, 12, and in the first 6 months of 1928, 3. These certified stains may now be purchased from all leading manufs.

C. R. F.

The history of staining. The cochineal dyes. H. J. CONN, N. Y. Agr. Expt. Sta., Geneva, AND S. I. HORNHAUSER, Univ. of Louisville Med. School. *Stain Tech.* 3, 110-21 (1928).—The history of the use of

cochineal dyes in biol. and histological work is carefully reviewed. Carmin is derived from cochineal by boiling with some salt such as alum which causes a ppt. of a partially purified product. Carmin is more variable in compn. than cochineal itself and for good results, the use of either carefully purified carmin or carminic acid is desirable. Numerous formulas are given. The bibliography includes 25 references.

Reactions of basic dyes with cyclic derivatives of an acid character. WALTER C. HOLMES AND RAYMOND M. MANN. U. S. Dept. Agr., Bur. Chem. and Soils, Wash., D. C. *Stain Tech.* 3, 122-30 (1928).—The recent discovery of French (*C. A.* 21, 1129) that the actual staining agent in the Ziehl-Neelson technic is an addn. product of the CaH₂OH and the dye employed led the authors to investigate the character of the reaction products of the various basic dyes with a considerable variety of cyclic derivs. of phenolic or acid character. Analytical data reported for the first time indicate

that basic dyes form addn. products with typical phenols. With more definitely acid cyclic derivs., the reaction is primarily metathetical, resulting in the formation of org. salts of the dyes. In some instances both metathesis and addn. result. The general method of prepn. of reaction products employed was that of adding to a concd. aq. soln. of the dye, a concd. aq. soln. contg. twice the amt. of the acid component. The reactions occurred at room temp. but hot, nearly satd. solns. were employed to insure max. yields. Cryst. ppts. were obtained on cooling. Among the addn. products prepd. were *rosanilin phenolate*, $C_{20}H_{20}N_3 \cdot OC_6H_5$; *phenol rosanilin hydrochloride*, $C_{20}H_{20}N_3Cl \cdot 2C_6H_5OH$; *resorcin new fuchsin hydrochloride*, $C_{22}H_{24}N_3Cl \cdot 2C_6H_4(OH)_2$; *hydroquinone new fuchsin hydrochloride*, $C_{22}H_{24}N_3Cl \cdot 2C_6H_4(OH)_2$; *resorcin crystal violet hydrochloride*, $C_{25}H_{30}N_3Cl \cdot 2C_6H_4(OH)_2$; *hydroquinone crystal violet hydrochloride*, $C_{25}H_{30}N_3Cl \cdot 2C_6H_4(OH)_2$; *chlorohydroquinone crystal violet hydrochloride*, $C_{25}H_{30}N_3Cl \cdot 2C_6H_3Cl(OH)_2$; *pyrogallol crystal violet hydrochloride*, $C_{25}H_{30}N_3Cl \cdot 2C_6H_3(OH)_3$; *phloroglucin crystal violet hydrochloride*, $C_{25}H_{30}N_3Cl \cdot 2(C_6H_3(OH)_3 + H_2O)$; β -*naphthol crystal violet* (formula not given); *crystal violet picrate*, $C_{25}H_{30}N_3 \cdot OC_6H_2(NO_2)_3$; *crystal violet acid phthalate*, $C_{25}H_{30}N_3 \cdot O_4C_8H_5$; *crystal violet 1-naphthol-4-sulfonate*, $C_{25}H_{30}N_3 \cdot SO_3 \cdot C_{10}H_6(OH)$; *crystal violet 1-naphthol-8-amino-3,6-disulfonate*, $(C_{25}H_{30}N_3)_2 \cdot (SO_3)_2 \cdot C_{10}H_6NH_2$; *resorcin methylene blue hydrochloride* (formula not given); *methylene blue salicylate*, $C_{16}H_{18}N_3 \cdot CO_2 \cdot C_6H_4 \cdot OH + 2H_2O$; *methylene blue acetyl salicylate*, $C_{16}H_{18}N_3 \cdot SO_2 \cdot C_6H_4 \cdot O_2C_2H_3$; *tetraethyl thionin acetyl salicylate*, $C_{20}H_{28}N_4 \cdot S \cdot CO_2 \cdot C_6H_4 \cdot O_2C_2H_3$; *azure C acetyl salicylate*, $C_{17}H_{22}N_4 \cdot S \cdot CO_2 \cdot C_6H_4 \cdot O_2C_2H_3$; and *methylene blue o-toluate*, $C_{16}H_{18}N_3 \cdot S \cdot CO_2 \cdot C_7H_7$. These new dyes may serve as valuable biol. stains.

C. R. FELLERS

Notes on stain application. R. W. FRENCH. Army Med. School. Wash., D. C. *Stain Tech.* 3, 130(1928).—Limited application has been made of the new cyclic derivs. of basic dyes described in the preceding abstr. to certain staining technics. Some of them have given very satisfactory results. In general, all act similarly to the usual phenol mixts. used in staining. When sufficiently sol. they gave very intense stains which, however, were difficult to differentiate. No definite conclusions may be drawn from this preliminary work.

C. R. F.

Investigation of thiazine dyes as biological stains. II. Influence of buffered solutions on staining properties. RACHEL HAYNES. Commission on Standardization of Biol. Stains, Geneva, N. Y. *Stain Tech.* 3, 131-9(1928); cf. C. A. 21, 1283.—The effect of buffer solns. of varying reaction upon staining fixed sections with thionine, azures A, B and C, and methylene blue was studied. The buffer solns. were employed as (1) a pre-treatment of the sections, (2) as a post-treatment and (3) as a dye solvent. Regardless of the method of employing the buffer solns. the intensity of staining increased with increasing p_H values, thus resembling the action of most basic dyes. It is uncertain whether this reaction is due to varying the p_H or to altering the salt content of the soln. or both. The staining intensity was greatest between the points p_H 5 and 6 or between p_H 6 and 7, its position varying with the method of fixation and of applying the buffer solns. It was further observed that between p_H 5 and p_H 7 there were always more pronounced metachromatic effects than with either more acid or more alk. buffer solns.

C. R. F.

Wright's as a differential spore stain. L. O. DUTTON. Methodist Hospital, Memphis, Tenn. *Stain Tech.* 3, 140-2(1928).—A method is outlined of differential spore staining utilizing Wright's stain dild. 1 to 5 in a phosphate buffer soln. of p_H 7.6 and following the general technic of the Dorner method. Spores are stained a deep blue while the cytoplasm of the sporangium is stained a pinkish red.

C. R. F.

A gasometric method for determination of reducing sugars, and its application to analysis of blood and urine. DONALD D. VAN SLYKE AND JAMES A. HAWKINS. Rockefeller Inst. *J. Biol. Chem.* 79, 739-87(1928).—The *Van Slyke-Neill* manometric app. was applied to the detn. of reducing sugars in blood or urine. The sugars are permitted to react with ferricyanide and the amt. of the latter reduced is detd. by treating with hydrazine and measuring the N_2 liberated. Highly accurate results are obtainable.

ARTHUR GROLLMAN

Note on the calibration of Barcroft manometers. MAURICE JOWETT. Univ. Liverpool. *Biochem. J.* 22, 717-9(1928).—A revised method of calibrating the Barcroft app.

BENJAMIN HARROW

Determination of succinic acid in blood. PERCIVAL W. CLUTTERBUCK. Manchester Univ. *Biochem. J.* 22, 745-8(1928).—A modification of Moyle's method (C. A. 18, 2198).

BENJAMIN HARROW

Determination of chloride in body fluids. JOCELYN PATTERSON. Charing Cross Hospital Med. School, London. *Biochem. J.* 22, 758-61(1928).—In plasma or serum: 0.1 cc. of the fluid is added to 1 cc. distd. water contained in a wide test tube. Add

3 cc. concd. HNO_3 , shake until the protein redissolves, then 0.5 cc. AgNO_3 (5.812 g. per l.) and shake again. Add 3–4 cc. acetone, mix, cool, add 8 drops (0.3 cc.) of satd. iron alum (indicator) and titrate from a microburet with alc. NH_4SCN of about $1/8$ strength of AgNO_3 and which had been standardized against the latter. B. H.

Some notes on the preparation of gold sols for the Lange test, with an account of a new method. F. S. FOWWEATHER. *Brit. J. Exptl. Path.* 9, 161–3(1928).—The success of the Lange test depends on the prepn. of a correct Au soln. Unless alk. adjusters are used the acid Au chloride salt cannot be used with success although the product commonly known as "gold chloride" is the acid salt, $\text{AuCl}_3 \cdot 2\text{HCl}$. Either the double salt with NaCl, viz. $\text{AuCl}_3 \cdot \text{NaCl} \cdot 2\text{H}_2\text{O}$ or the corresponding K salt may be used. F. prefers the K salt and avoids reduction at or near the p. p. The details of his method are as follows: Into a 200 cc. conical flask (from which any pptd. Au must be removed) are poured 100 cc. of freshly redistd. H_2O . One cc. of a 1% soln. of neutral K oxalate is added. Then 1.5 cc. of a 1% soln. of the Au K bromide is added. The whole is thoroughly shaken, the mouth of the flask protected from dust by a watchglass and the flask placed in a window where bright daylight reaches it. Direct sunlight should be avoided. The whole process from mixing and exposing the solns. to complete formation of the sol should occupy from 1 to 2 hrs. The final sol should have a faint sheen, giving the appearance of oiliness. Sols prepd. in direct sunlight may develop in half an hr. (depending somewhat on the temp.) but they are entirely without sheen and generally rather too stable. Sols taking more than 2 hrs. to develop are cloudy and unsuitable. In winter it is advisable to warm the H_2O to 25–30° before adding the reagents. In summer it is necessary that the H_2O after redistn. should be cooled thoroughly to room temp. before attempting the prepn. of the sol. On very dull or foggy days the method cannot be used. HARRIET F. HOLMES

The estimation of hydrochloric acid and enzymes in the stomach contents. FRANZ FRIEDHOFF. *Deut. Arch. klin. Med.* 160, 267–70(1928).—To est. the quantities of acid and enzyme bound to the solid stomach contents after various test meals, the residue after filtration of the stomach contents was washed with water till the washings were neutral; they were dried, and the adsorbed liquids were expressed by subjection to 250–300 atm. pressure. The concns. of acid and enzyme in the expressed liquid were roughly proportional to the concn. in the filtrate. P. Y. JACKSON

Is the finding of occult blood in small particles of feces conclusive? PAUL HIRSCH-MAMROTH. Polyclinic for Internal Diseases, Berlin. *Arch. Verdauungs-Krankh.* 43, 247–11(1928).—The presence of blood in small particles of feces was verified in 70 cases. FRANCES KRASNOW

The practical value of the determination of gastric pepsin. FRITZ HIRSCHBERG. *Arch. Verdauungs-Krankh.* 43, 211–9(1928).—The Boas method makes the detn. of pepsin very simple. It is especially valuable in cases of nervous influences on the gastric secretion. FRANCES KRASNOW

Microchemical identification of chitin. WILHELM KÜHNELT. *Biol. Zentr.* 48, 371–82(1928).—Deeply incrustated and pigmented objects are heated at 300° with glycerol or bleached with HCl and KClO_4 . For slight incrustation this treatment may be omitted. 50% KOH is added and the mixt. in a sealed tube is digested at 160° to 180°, cooled, centrifuged and washed with alc. and water. The chitin, thus obtained, is heated with KI soln. (I_2 —2 g., KI—1 g., water—200 cc.) and then with 10% H_2SO_4 . A dark violet color indicates the presence of chitin. If the prepn. is heated until the chitosan is completely dissolved and then cooled at 70° there appear spherical crystals of chitosan sulfate which turn violet in the presence of I and show the Brewster lines between crossed Nicol prisms. FRANCES KRASNOW

A normal sheep urinalysis. DANIEL J. HEALY, JOHN F. BULLARD AND HOWELL D. SPEARS. Kentucky Agr. Expt. Sta. *J. Am. Vet. Med. Assocn.* 73, 87–91(1928).—There was found urea 2.5, NH_3 0.01 and N 1.4%; no sugar, albumin, or acetone; some amorphous urates and Ca oxalate crystals. FRANCES KRASNOW

The estimation of silica in tissues. EARL J. KING. Univ. of Toronto. *J. Biol. Chem.* 80, 25–31(1928).—A colorimetric micro-method for the estn. of SiO_2 in tissue ash is described which makes use of the intense yellow color of silicomolybdic acid. Phosphoric acid is used as an artificial standard. Phosphate is removed by magnesia mixt. The following max. values were obtained for the silica content of some animal tissues (mg. per g. of fresh tissue: guinea-pig lung 0.12, rabbit lung 0.30, dog lung 0.39, rabbit kidney 0.34, dog kidney 0.21, rabbit liver 0.46, dog liver 0.34, dog spleen 0.16. In normal human lung 1.4 mg. of SiO_2 per g. of dried tissue was found; in silicotic lung 12–15 mg. A. P. LOTHEROP

Chemical and biological analysis of *digitalis lutea*. G. M. PICCININI. *Boll. soc.*

ital. biol. sper. 3, 509-11(1928).—The Keller-Kiliani reaction took place with the same rapidity and intensity for lutea as for purpurea (+++). The percent digitalin using the "Farmacopea Militare" 1916 method was 0.321 for lutea and 0.338 for purpurea. The injection of 1 cc. of a 10% infusion into the dorsal lymph sacs of frogs caused systolic arrest in 30-29-32 min. with lutea, and 25-28-35 min. with purpurea. The lutea leaves were collected in various regions of Northern Italy. The recommendation is made that *D. lutea* be used as a substitute for *D. purpurea* in Italy on account of its greater diffusion in this country.

PETER MASUCCI

The determination of phosphagen in various organs. G. MARTINO. *Boll. soc. ital. biol. sper.* 3, 622-23(1928).—The presence of phosphagen was detd. by Briggs' method, modified by Eggleton, in brain, kidneys, liver, spleen, lung, thyroid, suprarenal capsules, pancreas, ovaries and salivary glands. In none of these organs was there even a trace of phosphagen found. Blood also gave neg. results. Phosphagen is, therefore, found only in muscular tissue.

PETER MASUCCI
